It further holds that the right of service of water from a public utility does not bring the lands so furnished under the protection of Section 552, Civil Code, and such right of service is not a vested right or a right appurtenant to the land.

Effect of Agent's Admission of Liability

Verdict upheld where letter from agent admitting liability for damages had been admitted as evidence.

In the case of Trueman v. Sutter Butte Canal Co., 49 Cal. App. Dec. 242 (January 23, 1926,) a letter from the engineer of the Company was offered in evidence wherein it was stated "The Canal Company has contributed to some extent to the general seepage condition in the orchard, but the major portion of the damage is due to rice irrigation. The Canal Company is willing to assume $250.00 of this damage, being the amount of damage due to direct seepage from our canals. . . . " The introduction of the letter was strenously objected to by defendant but was admitted as "an admission by the defendant, through an authorized agent, that the defendant did contribute to the damage of plaintiff's orchard."

On appeal the question arose as to the correctness of an instruction to the jury where the court failed to allow the jury to consider any question of the manner of the construction of the ditch but in effect made the company an insurer against damage arising from maintaining and operating the ditch.

Appellants cite various cases showing that ditch owners are not insurers but the Appellate Court holds that they are not called upon to attempt to differentiate, even if it may be done, between the case cited and the instant case, as the instructions could not be held to have worked prejudice as against the defendant, in view of the fact that defendant (through the letter of its engineer) expressly admitted liability, at least in part, for the damage. The verdict of the jury was upheld.

Status of Unofficial Engineering Reports

Unofficial reports of engineers are not admissible evidence in condemnation proceedings.

In the case of City of Stockton v. Vote, 49 Cal. App. Dec. 315 (February 2, 1926), where the City was condemning lands for the purpose of constructing a dam to control flood waters and thereby submerge certain lands, a report of an engineer was allowed in evidence, without objections, but the Appellate Court held that it was inadmissible in evidence as being only an unofficial compilation of statistics and the opinion of the engineer.

Evidence was also introduced, over objections, as to the value of the property to the City of Stockton and the Appellate Court held that in a condemnation proceeding the necessities of the public are never taken into consideration in fixing the value.

The judgment was reversed but appellants were taxed with the costs of appeal as under the law a land owner is entitled to the full value of his land, when finally ascertained, exclusive of costs.

Districts' Powers Limited by Statute

Irrigation Districts have only such powers as are expressly given them by act of the legislature.

In the case of Bottoms v. Madera Irrigation District, 48 Cal. App. Dec. 366; 242 Pac. 100; (October 27, 1925) the plaintiff brings an action against the district to recover the sum of $176,000 for services rendered in causing a settlement to be made of the differences between Miller & Lux and the district. The so-called contract was repudiated by the district.

The court holds that the contract was beyond the power of the Board of Directors, ultra vires and void. It further holds that

(*Continued on Page 25*)

THE HYDRAULIC DIGEST

A Monthly Bulletin Board of Brief Facts and Events from Far and Near

Complete Antioch Reservoir

Citizens of Antioch, California, are rejoicing in the completion of the Antioch Reservoir, said to have solved the community's problem of water supply. The capacity of the reservoir is 60,000,000 gallons.

Would Sell Water Works

S. E. Throwell, owner and operator of the Lomita Water Works, serving Lomita Park, California, has applied to the railroad commission of that state for authority to sell the system to Daisy Noe.

Redlands to Vote on Bonds

Redlands (California) voters will ballot on April 12 on the question of whether the city shall bond itself in the sum of $525,000 for the purchase of the "Zanja," historic mountain irrigation stream, now owned by ranchers of the "old town" west of the city.

Plan Co-operative Project

Action has been taken by citizens of Ravenswood, California, for the incorporation of the East Almond Co-operative Water Company, a non-profit organization which proposes to develop water for the irrigation of lands owned by its members.

Bellingham Takes Over System

Bellingham, Washington, has taken over the operation of the South Bellingham water system of the Fairhaven City Power and Water Company. The system was acquired at a cost of $165,000, for which bonds were voted by the city. The bonds were purchased by local financial institutions.

May Buy City System

A committee has been appointed by the city trustees of the city of South San Francisco to make a study of the properties of the South San Francisco Water Company, with a view to reporting on the feasibility of its purchase by the city. The value of the property is appraised at $485,000.

Salt River Users Have Plenty

An official statement from the Salt River Valley Water Users' Association declares that there is no cause for alarm, in connection with the water supply for the coming year, on the part of water users in the valley. The statement asserts that the association has available at this time the same water supply as last year, and that the pumping system will adequately supplement the stored supply.

Water for Roosevelt District

First water was supplied to the lands of the Roosevelt Water Conservation District during February when a 1,000-inch pump began to pour water into the main canal of the district, taking its supply from the south canal of the Salt River Valley Water Users' Association. Three other large pumps will soon be in use at the intake, while the other pumps at various points will provide sufficient water to cover the 41,000 acres of the project.

To Build Ten Miles Levees

The Colorado River Land Company has called for bids on the construction of ten miles of new levee along the river east of the Volcano Lake Basin. The new levee will be an extension of the existing Pescadero Dike, running south from the Pescadero Dam, and will be built in connection with an additional two and one-half miles of new levee which is to be paid for jointly by the Imperial Irrigation District and the Colorado River Land Company.

Promissory Notes Authorized

The farmers Irrigation Company, Santa Paula, California, has been authorized by the state railroad commission to issue $55,000 of its unsecured promissory notes for the retirement of outstanding notes; $18,000 of additional promissory notes payable in three years; and $29,000 additional common stock; and to deliver the three-year notes and stock, together with $14,600 in cash, in payment for water properties recently acquired from the Limoneira Company.

Refuses System Purchase

City of Vallejo, California, has decided against the contemplated purchase of the Bay Terrace water system. Negotiations touching the transaction have been in progress since the city first undertook to purchase the system in 1921 and later declined to complete the deal.

Arizona Bonds Purchased

Sutherlin, Barry & Company, New Orleans, were successful bidders in the sale of the $112,000 bond issue of the New State (Arizona) Irrigation and Drainage District, consummated in February. The funds from the sale will be turned over to the Salt River Valley Water Users' Association for use in the development of the lands of the New State district, by means of a pumping project.

Enlargements for Moreno

Improvements undertaken in the water system of the Moreno (California) Mutual Irrigation Company will cost approximately $160,000, to be spent within the next four months, according to plans which the company announced in February. The improvements involve the construction of a pipe-line from the town of Moreno to wells on the company's property in the San Timoteo Canyon, including 31,000 feet of 24-inch steel pipe and re-inforced concrete pipe, and 2500 feet of short tunnels. It will carry water for the irrigation of 3500 acres.

Yakima Bond Sale Delayed

Water revenue bonds of the city of Yakima, Washington, in the amount of $1,050,000, which had been conditionally purchased by a syndicate of Seattle banking houses, ran into an unexpected delay late in February when the purchasing syndicate asked for an extension of sixty days in their preferential purchase rights. The attitude of the purchasers is that the water system contemplated under the bond issue is economically defective. They object to the use of wooden pipe in the distribution system, believe that the estimate of revenues was over-optimistic, and the estimate of operating expenses too low.

Irrigation Creates a New Industry

(*Continued from Page 12*)

years. A. J. Shamblin, Superintendent of the United States Date Experiment Station at Indio, has directed the work under the auspices of the Bureau of Entomology of the Federal Horticultural Board. The results have been very gratifying, and the final success of the campaign of extermination seems probable.

DATES ripen from September to December and attract thousands of visitors. To the average city dweller, a trip to the Coachella Valley during the harvest season seems like a visit to the Sahara or Mesopotamia. Graceful green palms bearing huge bunches of luscious fruit have a romantic appeal not found in other products of California.

The demand for California dates has kept pace with, and even surpassed the rate of production. This been due to several causes, the foremost being the excellent flavor of the fruit. The name of the person who first described Coachella Valley dates as "nature's finest confection" is unknown, but he deserves much credit for such a happy thought so well expressed. Inferior varieties, which are now in the process of being eliminated from the valley, or the lower grades of the standard varieties, do not, of course, fulfill the expectations of a purchaser, so care must be taken when a novitiate buys dates for the first time that he secures the best. In the United States the total consumption of both domestic and foreign dates last year was approximately half a pound per capita. This comparatively small amount indicates that the day of overproduction is far in the future.

A number of the smaller growers sell their entire crop fom their back doors or from road-side stands, others pack and ship their fruit to commission merchants in the larger cities. The major portion of the crop, however, is put through modern packing houses where great care is taken to prepare and pack the fruit in a sanitary manner. Cleanliness is another reason for the active demand now enjoyed by California dates.

The Deglet Noor Date Growers Association, with its headquarters and packing house at Indio, is a growers cooperative modeled somewhat after the orange or walnut growers associations. This association has a membership of 43 growers and the largest output of any similar organization. Deglet Noors are handled almost exclusively, the only exception to the "one-variety" policy being a few hundred pounds of Thoorys which are brought in by the members. The Thoory is considered the best of the "bread dates" and, being dry and hard, is easily handled.

The Narbonne Ranch and George Beach also operate well equipped packing houses in the valley, though not specializing in any one variety. Several packing houses have been established in towns near Los Angeles where dates from the Coachella Valley are prepared for the market. The Valley Packing Company has a large and modern plant in Monrovia, the Marvin Date Company has its plant in Riverside, the Date Corporation of America is located in Alhambra and the Cowgill-Conner Date Company has its plant near Pasadena. The two last mentioned also specialize in Deglet Noors.

AN INTERESTING feature of the date industry is the class of people who have adopted date growing as their hobby or their life work. It would be hard to find an industry where so high a general level of intelligence prevails. Professional men of all classes, business men from several different lines of work, (and women too, of course), skilled mechanics, farmers and citrus growers are all represented. About nine years ago, C. E. Cook, formerly in the electrical supply business in Los Angeles, secured a large tract of land in the Indian Wells district and started a date garden. Knowing that there were others who would like to own date gardens but who were prevented by business or other reasons from making developments personally, he sold portions of his land under contracts to plant and care for date gardens. Most of these palms are in bearing now and their owners are highly pleased with results. The list of owners includes a lawyer, a business woman, two high school principals and three others also engaged in educational work. Mr. Cook is now engaged in opening up another tract of land and it will be interesting to classify the new list of date enthusiasts.

Residents of the valley believe that sooner or later the waters of the Colorado River will be available for use and with the coming of cheap water that the Coachella Valley will enter upon an era of development that will far exceed anything that has occurred in the past. The rich soil will bear bountiful crops and eventually the Coachella date will take its place with the orange and the raisin, to be known all over the nation.

Why Are Our Irrigation Organizations?

(*Continued from Page 18*)

improvements and particularly public works? Should we, at this time, before constructing railroads, highways, and other improvements, along our public streams, give some consideration to the future hydraulic development that may be made thereon?

THIS institution is known as an Irrigation Congress, but I am sure we can now fully realize the value of water for other purposes and thus the necessity of coördination in the various uses to which it may be beneficially applied. We can therefore no longer consider irrigation development standing alone but must take into account the use of water for manufacturing, power, domestic and other purposes.

As our population increases the demand for wholesome, potable, domestic water becomes more important and as our industrial growth continues the value and need of energy likewise increases.

The use and protection of our watersheds now largely given over to national forests and open public domain presents a problem of importance quite aside from the question of grazing, which is now pending before Congress for a solution.

We are confronted with hydraulic and water supply problems of an inter-state nature that are demanding solution. The most immediately important of these exists on the tributaries of the Columbia River, Pend d'Orielle, Priest and Coeur d'Alene Rivers and lakes of the same name. The state is called upon to outline its future needs and to enter into a compact with three other states, effecting an allocation of this water supply among them and dedicating the same to various uses. The solution of this problem requires careful study, the exercise of keen judgment and mature foresight.

It is a question whether this Congress is the proper organization to give these problems attention and whether it can function in a capacity which will find a solution for them. In a government such as ours, these, and most other public questions, must after all find a solution in an expression of public sentiment. This being true, if we are to arrive at a proper solution, some means must be employed to give the public the facts.

Our legislature convenes once every two years, each session being confronted with many requests and suggestions for laws designated to outline the conditions under which our natural resources may be utilized. These cannot, without a previous crystallization of public senti-

ment, receive adequate and properly coordinated consideration.

UNDER the laws and constitution of Idaho as they now exist, neither the state nor any of its institutions has a right to say whether a proposed use of water resource is really in the interest of the state and constitutes the greatest possible beneficial use to which it might be put. Perhaps this is a wise provision but on the other hand I am inclined to the belief that it is a matter that warrants our careful consideration. Can we, under this condition, expect to complete the development of our water resource and secure the greatest benefit from it to the state as a whole?

These problems are not limited to the state of Idaho. It is my belief that they will find a correct solution only through some organization or institution dedicated to unselfish public service. You gentlemen should come to some conclusion at this session as to whether or not there shall grow out of the Irrigation Congress an organization dedicated to a solution of these problems.

Irrigation in Colorado

(*Continued from Page 19*)

function. Of a truth it may be said that Colorado is pre-eminently an agricultural state, but all this as a result of her irrigation institutions. Is it, then, passing strange, that with her future inseparably joined with this great industry, she considers her water supplies her greatest asset, and looks anxiously ahead to the safe-guarding of this precious heritage which means so much to her people? For upon the successful protection and administration of this, her greatest resources, depends her present prosperity and the future development of her tremendous potential resources, which is of such vital importance to Colorado, and of material moment to the nation at large. Those pioneers in irrigation practices and jurisprudence who framed Colorado's constitution and laws builded wisely and well for the safe-guarding of this great industry, a monument to their sagacity, a blessing to her people, and a bulwark to a nation.

To Investigate Extension

Citizens of Cle Elum, Washington, were greatly interested by the suggestion made before a service club of that city by Superintendent Lytel of the Yakima project favoring the extension of the proposed Kittitas high-line canal as far as Cle Elum, to irrigate 5,000 acres of land lying east of the city, and to add to the municipal supply. Funds for an investigation of the possibility of obtaining such action have been appropriated by the city.

Federal Reclamation Spending $25,000,000 in New Work

Reclamation under federal control is spending approximately $25,000,000 in new construction of dams, canals and irrigation works on twelve different projects, according to an official report, which declares that the work now going on is the largest to be undertaken since the original major projects were built.

Three large dams, the McKay dam on the Umatilla (Oregon) project, the American Falls dam, Idaho, and the Guernsey dam on the North Platte River are the largest of the works now under construction. In addition to these dams, construction work is in progress on a number of other federal projects.

On the Yuma project, a 1,200 horse power hydro-electric plant is under construction, at a drop in the California main canal. This plant will cost about $250,000, and will furnish power for pumping water to the Mesa division lands in Arizona. The foundation of the plant has been completed and the contractor has commenced the erection of the power house.

On the Grand Valley project, Colorado, a siphon spillway is being constructed at the Orchard Mesa pumping plant, and excavation is also being carried on with draglines at a number of points in connection with drainage work at a cost of $200,000.

On the Boise project in Idaho, riprap is being placed for the bank protection and a concrete parapet is being constructed on the main canal in order to increase its capacity, the cost being $278,000.

On the North Platte project the enlargement of the Interstate Canal is in progress and the construction of the Laramie River diversion canal is under way at a cost of $465,000.

On the Carlsbad project, New Mexico, concrete lining of the main canal is in progress and on the Rio Grande project in the same State several dragline excavators are being utilized in the construction of drains, levees, and canals, the total cost being $1,016,830.

On the Klamath project in Oregon, enlargement of a number of canals is in progress at a cost of $58,700.

On the Yakima project, Washington, canals are being lined with concrete on the Tieton division, and a wasteway is being reconstructed on the Sunnyside division, the cost being $65,000. On the Kittitas division rights of way for 27 miles of the main canal are being purchased and specifications are being prepared for the early letting of contracts that will involve an estimated expenditure of $7,500,000.

On the Riverton project in Wyoming, construction of the Pilot Butte dam embankments are in progress together with some lateral excavation. The Pilot Butte dam embankment will be 42 feet high, 2,400 feet long, and contain 200,000 cubic yards of material. Its cost will total $189,000.

On the Shoshone project in Wyoming, contract work is in progress on the Willwood division for the construction of canal and laterals at a cost of $290,000.

Recent Court Decisions

(*Continued from Page 22*)

irrigation districts are public corporations or agencies, and have only such powers as are expressly given them by the Legislature, under and by virtue of which they exist, or are necessarily implied to carry out the purposes of the district. That any one dealing with the district is chargeable with knowledge of all the powers that officers of such district possess, and all contracts beyond the scope of such powers are void, and knowledge must be taken, not only of extent of power, but also the mode in which it may be exercised.

Transfer of Moneys Between "Funds"

The changing of money from one fund to another by an irrigation district does not change the true status of such money.

In the case of State vs. District Court, 242 Pacific 431, (December 23, 1925) the Supreme Court of Arizona held that the Board of Directors had no authority to transfer money from the construction fund of an irrigation district to a so-called "hold back fund" or other fund except where there is a surplus upon the completion of the district project.

The mere direction of the district to the County Treasurer by the resolution to designate portions of this fund by some other name and the compliance by the Treasurer with this direction by bookkeeping entries in her records, did not change the status of the fund. It still remained the construction fund, although called by other names.

Irrigation Bonds General Liens

Under Oregon laws, the bonds of irrigation districts are general lien obligations.

In the case of Noble v. Yancey, 241 Pac. 335 (Dec. 2, 1925) the Supreme Court of Oregon held that under the statutes of that State, bonds of an irrigation district are general lien obligations, requiring the assessment of all the lands in the district for the payment of principal and interest, which necessarily requires the assessment of each current year to be sufficiently broad to take care of actual and contemplated delinquencies in prior assessments.

The Oregon law differs from the California Irrigation District Act in having a special provision in its act providing that "In case the amount assessed against any tract of land shall not be paid the next assessment against the land in the district shall be so increased as to take care of such default," but the court holds that this section did not change the prior and general law to the effect that the liens of the bonds are general liens against the lands of the district. The case also distinguishes certain decisions which held that the liens of irrigation district bonds were not general liens.

HYDRAULIC ENGINEERING

Dealing with the Practical Problems of the Operating and the Consulting Engineer

CO-OPERATING IN SURVEYING OUR WATER RESOURCES

How the States and the U. S. Geological Survey Work Together

By N. C. GROVER*

OCCASIONALLY great excitement is caused by the discovery of a rich gold field, resulting in a rapid migration of adventurers who hope to make fortunes by mining. Discoveries of gold or other precious metals lead men to undergo hardships and danger in order to take a chance on being lucky enough to "strike" a rich mine, and yet, over a period of years, the average annual value of the gold taken from the ground is insignificant in comparison with that of the products of agriculture or manufactures.

Water, a mineral that is even more valuable than gold, is so commonplace that its value is often overlooked. In fact, it is only in connection with a shortage of water that its value is appreciated by many people. When that condition is reached and especially when water is seen to limit development along any line, as it now does in this country along many lines, there is a demand for the collection of reliable data in regard to the nation's water resources.

The total amount of water available for use in any region cannot be increased, except here and there, by diversions from nearby rivers. Its distribution throughout the year may be modified by means of storage, but the total quantity is a direct result of precipitations which cannot, so far as now known, be changed by any act of man. This statement applies with equal force to ground waters which also are derived from precipitation. The variability in the flow of streams from month to month and year to year, and the inability of anyone to predict with confidence what the future flow of any stream may be, except by study of records of the past behavior of that particular stream, have forced engineers to conclude that reliable records of flow of many streams ranging in size from the largest to the smallest are absolutely essential to safe and sane development along many lines.

WATER has always been recognized as a necessity for both plant and animal life and deficiencies in supply were first recognized as important in connection with irrigation. Suitable and adequate water supplies for cities and towns have for many years required the services of the best engineers of the country. More recently, the marvelous growth in the use of electric energy has brought strikingly to attention the limit which the available water supply puts on the size of power plants, both hydro and steam, and has shown that the amount of water in a region determines the limits of development of industries, the growth of cities and in many regions the extent of agriculture.

For the design of hydraulic works that are to remove water, a knowledge of the maximum amounts to be removed is just as essential as is knowledge of the amount of water to be used or to be controlled for the design of hydraulic works that are to promote use or control. Everyone who has to do with water, whether to use or remove it, needs, therefore, reliable records of the quantities available or to be removed at all seasons.

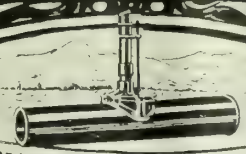
Under continued Federal appropriations extending over 30 years, the United States Geological Survey has become the authorized Federal agency for collecting and publishing data pertaining to water and is the recognized source of reliable information in regard to all questions relating to water supply. As the Survey, which is primarily a Bureau of research and investigation that collects and publishes for general information and use data in regard to the natural resources of the country, has been unable to extend its water resources investigations to keep pace with the need for data, governmental and private agencies have sought its cooperation in extending the investigations of water supply. This cooperation has increased greatly in recent years and now involves thirty or more states.

More than $500,000, in addition to the regular Federal funds, has been contributed annually in recent years by states, counties, municipalities, and corporations operating under the Federal Water Power Act. Twenty-five district and sub-district offices are maintained by the United States Geological Survey for carrying on field work. An experienced engineer and competent assistants are assigned to each district and by residence there make themselves familiar with local problems and needs and facilitate conferences with local cooperating officials.

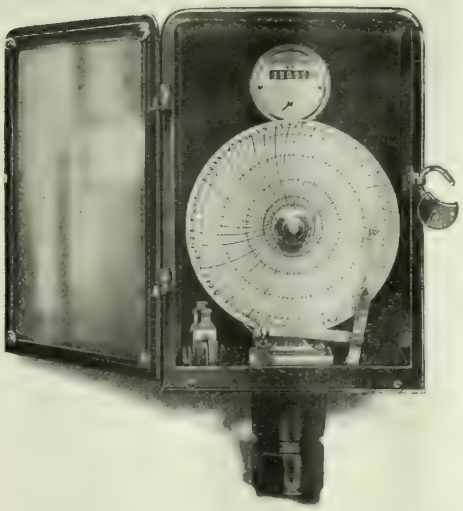
A few state officials have felt, at first, that their problems did not require the collection of complete records; that they were interested, perhaps, only in the floods and, therefore, needed only the records of high stages, or only in the low flow and needed to study only the periods of draught. All have now learned, however, that if reliable records at particular stages are needed, the river station must be established, rated carefully and maintained continuously, because otherwise the records of extreme stages either will not be collected or will be insufficient for correct interpretation into quantities of discharge at the peaks or into total run-off in the flood season, the two quantities that are always needed. In general, the equipment and the personnel must be ready and functioning regularly or records of extreme stages, which are the most difficult to collect and interpret, will not be made. In flood seasons, the combination of impassibility of highways, interrupted railroad schedules and shortness of peaks of floods makes the collection of flood records, except as a part of complete records, difficult, expensive and disappointing.

AFTER varied experiences with the many different problems that arise, most states have recognized the advantages to be obtained by cooperating with the United States Geological Survey, which has a staff of trained engineers qualified by experience and furnished with all needed equipment of the latest and best design, to collect reliable records at a minimum cost. Besides its large force of engineers who study the

*Mr. Grover, who is chief hydraulic engineer for the U. S. Geological Survey, presented the accompanying article as a paper before the recent National Drainage Congress at Oklahoma City.



ACCURATE WATER MEASUREMENT PAYS



Furnishes a Graphic Record of Your Flow Distribution

Here is a new device produced and tested by our research department, that records the flow either upon a daily or weekly basis

SPARLING METROGRAPH

Equipped, as you prefer, with either 4 feet of flexible cable, so that you may place it where convenient or for mounting on the standard meter register extension.

A dependable, 8-day clock and easily read flow sheets, will furnish you with a valuable and interesting story of your flow distribution

surface waters, the Survey has a corps of ground-water geologists experienced in the problems related to the occurrence and recovery of ground water, and, in addition, a group of chemists trained for studying the chemical quality of water with respect to its use in agriculture or the industries, and a chemical laboratory especially equipped for this work.

The nature and terms of the cooperation vary as the problems and available funds vary in the several States. The amount of Federal money that can be allotted for cooperative use in any State is, however, generally no more than enough to pay the salary of the district engineer. The amount of work that can be done is wholly dependent on and nearly directly proportional to the amount of cooperative money that can be allotted.

In general, it is not practicable to attempt the establishment and operation of a district office with less than $10,000 annually in the total fund available for the work, and preferably the fund should be considerably larger. With that or a greater amount available, a district office is established in a state and an experienced district engineer put in local charge. The work to be done will be decided in conferences between the district engineer and the cooperating officials, the wishes of those officials being followed in general. The work having been decided on, its technical conduct will be entirely within the control of the officials of the Geological Survey who will select methods, equipment and personnel, having due consideration for costs of the work and the funds available therefor.

Federal funds are so meager that it is uneconomical to conduct work in a state that does not cooperate in a sufficient amount to warrant the establishment of an office. Stream gauging cannot be conducted economically or satisfactorily by engineers who live at a great distance from the work. The waste of time and money in travel is great, and the records collected will not be accurate because of the impossibility of having engineers on the spot promptly when needed and of the certainty that too little work will be done at the cost involved in sending men from a distance.

For several years past cooperation has been requested far in excess of the funds that the Survey could allot to the work. Because of this situation, there has been an insistant demand by State officials that Federal funds for studying water be increased. This demand has culminated in a bill, introduced in this Congress by Honorable W. H. Newton, of Minnesota, providing for an inventory of the water resources of the country to be made by the United States Geological Survey in cooperation with States and other governmental agencies and authorizing annual Federal appropriations of $500,000 in each of 20 years except the first when $400,000 is authorized.

The bill was drafted and is sponsored by the American Engineering Council and has the endorsement of Federal bureaus, cooperating State officials, many local and national engineering societies, and engineers in private practice who deal largely in problems relating to water. The Council has summarized the reasons why this inventory should be made by and in cooperation with the United States Geological Survey as follows:

1. The Geological Survey is primarily a bureau of research and investigation that collects systematically and publishes for general information and use data in regard to the natural resources of the country and it is recognized as an authorized Federal agency for collecting and publishing information in regard to all questions relating to water resources of the country.

2. The Geological Survey has an established personnel and facilities for carrying on the investigations. The methods used in conducting the work have been developed as a result of years of experience and have been accepted as standard throughout the United States, and foreign countries. This insures co-ordination and standardization of all investigations conducted by the Geological Survey or under its supervision.

3. The work of the Geological Survey is on a continuing basis and is reasonably free from danger of interruptions with changes in administration.

4. The Geological Survey is in position to make data readily available to the public by means of its publications and of other facilities.

5. It is highly important that base data in regard to water and other natural resources be collected by an unbiased agency not directly interested in construction or administration of specific projects or of specific types of projects in order that the public may have absolute confidence in the results. Moreover, agencies responsible for construction or administration are most soundly fortified if their actions are based on information collected by an accredited federal investigational bureau whose primary responsibility is that of making available unbiased facts.

An Outline of Irrigation

(Continued from Page 14)

Our past work in determining the laws governing the flow of water in canals and other conveying channels used in reclamation is recognized as authoritative not only in this country but in foreign countries. The work of this Division along lines of canal operation and maintenance, reclamation organizations, canal and ditch structures, water requirements of soils and plants, alkali reclamation and the drainage of irrigated lands together with many other lines of research already mentioned or that will be mentioned, constitute the field which we have occupied in reclamation during the past thirty years. It has been our effort to guide the irrigator with a view of making his position more profitable and secure.

Diesel Power as One Solution for Drag-Line Difficulties

By JAMES O. QUILLER

RECLAMATION contractors, engineers, and other users of excavating equipment are exhibiting more than ordinary interest in the application of Diesel engine power to small draglines, shovels and similar excavating equipment so widely used on hydraulic projects.

"It should have marked advantages, undoubtedly, over some of the power units used on shovels and ditching machinery," said a well known contractor to me, during the recent Western Road Show at San Francisco; "but I shall want to be convinced that the chief objections to the Diesel have been entirely overcome. The idea itself, of course, is not original; it has been simply a question of adapting the Diesel to this use or that, wherever practicable, but for many purposes we know that this type of plant has not yet qualified—for use on automobiles, for example."

With the view of clearing up the main points of doubt, as to precisely how the Diesel performs when used on a dragline machine, and how this latest innovation is proving up in the hands of users, I went directly to the manufacturers, the Northwest Engineering Company of Chicago. C. R. Dodge, general sales manager of the company, in his reply tells how vibration—one of the major objections to the Diesel as heretofore applied to the dragline, because confined to three cylinders—has been eliminated, and explains many other features of interest to dragline operators.

"For years," says Mr. Dodge, "the material reduction in the cost of operation has been the goal sought by every manufacturer of shovels, cranes and draglines. The Diesel principle of internal combustion has offered the nearest approach to real economy, but to date the excessive bulk and vibration of the Diesel has made it a questionable form of power for shovel, crane or dragline service.

"For a long time the Northwest Engineering Company, the largest exclusive builders of gasoline and electric shovels, cranes and draglines, has given consideration to the Diesel and its relation to this class of machinery. This concern was not willing, however, to put such an engine on the market till able to overcome those common troubles in the present small Diesel. Excessive vibration must be eliminated, complete combustion assured, and many of the mechanical difficulties corrected.

"After five years of experimentation and study on the problem of the Diesel, the Northwest Engineering Company has announced the Northwest-Cummins Diesel Engine. Unlike the oil engines now being placed in service on shovels, cranes and draglines of from ¾ to 1¼ yd. capacity, the Northwest-Cummins utilizes 4 cylinders. Thus all objectionable vibration has been eliminated and smooth operation is assured."

"The Northwest - Cummins," continues Mr. Dodge, "is a real Diesel in every respect, not a semi-Diesel, and it brings all the advantages of the original Diesel principle unmodified, as in the case in the many solid injection engines at present on the market.

"It starts from stone cold, without the aid of torches, electric hot spots or other similar device, and runs at a full Diesel compression of 500 lbs. pressure. This assures full economy of operation.

"This, as well as the complete combustion without the use of the troublesome high pressure air compressor, is accomplished by means of the peculiar and novel means of fuel injection. The fuel pressure is only 50 lbs. This makes possible the use of needle valves of the simplest type and allows the most accurate metering.

"Air is actually injected with the fuel, as in the original Diesel, but instead of coming from a high pressure air compressor it comes from the combustion chamber itself on the compression stroke.

"The 4 cylinders of the Northwest-Cummins are cast separately, allowing easy removal of either half of the five main bearings as well as the easy removal of any cylinder with minor alterations to the rest of the machine.

"All parts are extremely sturdy and heavy. The fuel pump is very simple and serves the purpose of keeping the pressure up to 50 lbs. only, and not as a fuel meter as is the case in most small Diesels. Operation is cool, the water jackets never approach the boiling point, even after hours of work on hot days. Lubrication is full pressure feed throughout and is carried to the piston pins.

"For starting, a small gasoline engine and an air compressor are provided. The compressor charges a small storage tank that has capacity for from 10 to 15 starts. Twenty minutes daily operation will keep this tank full.

"The primary advantage of this engine is of course low cost of operation. Northwest machines equipped with the Northwest-Cummins are operating at a cost of 90 cents a day."

Republic Electrical Liquid Level Recorders

These instruments have a wide application wherever the correct knowledge of liquid supply in tanks, standpipes, reservoirs, irrigation, etc., is desired.

The Reading instruments can be either Indicating, Recording or both (as in the above illustration showing reading instruments installed at Endicott-Johnson Corporation Water Works). The Reading instruments can be located at any distance from the place where pressure or level record is taken.

MANAGEMENT

GAS ADVOCATED AS FUEL FOR IRRIGATION PUMPING

By F. M. BANKS

THE CLAIMS and costs of electric power for pumping irrigation water have been given in previous issues of MODERN IRRIGATION. *In this article F. M. Banks, sales supervisor for the Southern California Gas Company, presents the case for gas, which he asserts is a superior source of power under certain conditions, and which is widely used in irrigation, especially in southern California. The article is a much condensed abstract of a paper which Mr. Banks delivered before the Pacific Coast Gas Association in February.*

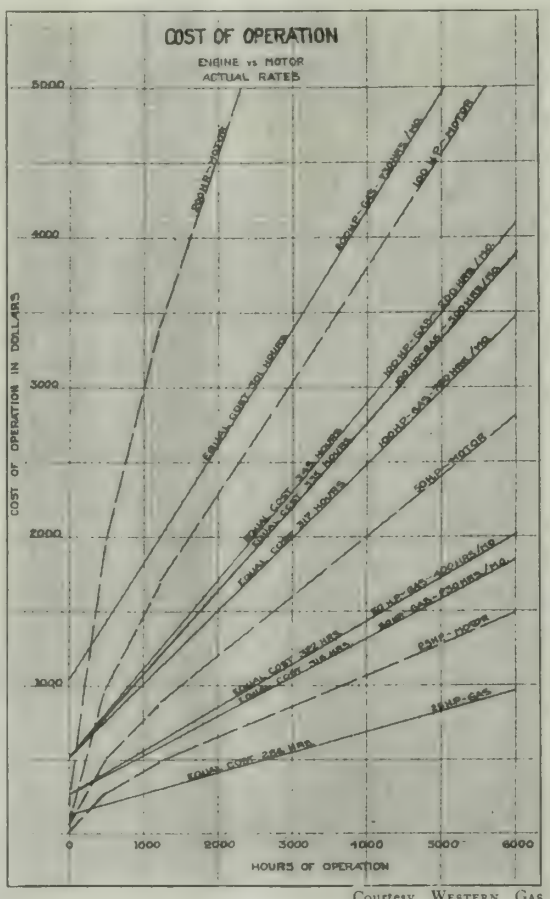
IN SOUTHERN California a relatively large portion of the water required for irrigation must pumped. Furthermore, there are some areas in which the water level is quite low, often exceeding a depth of 200 feet below the surface. The prevalence of these conditions is responsible for the installation of a large number of gas engines for this work.

At the present time there are almost 400,000 active gas engine horse power connected in Southern California from Bakersfield south. In the last few years installations have been made at the rate of about 50,000 horse power per year. In 1925 the increase was nearer 75,000 horse power. A good portion of this horse power operates continuously in oil company and gas company work. The remainder, something like 25 per cent, is used in agricultural and industrial work.

POPULARLY, gas engines are considered unreliable, subject to shutdown from numerous causes, liable to excessive repairs, difficult to start and subject to constant attention. All of this is the result of experience with old types of engines using liquid fuel, of high speed engines on constant loads, and of the uniformly sad experience with engines operating on continual overload. These impressions are kept fresh in the minds of power users by salesmen for other equipment.

As for shut down, data collected for a year in one case discloses the fact that engine shutdowns for all causes were about one-seventh of the shutdowns of electric motors, and the time of shutdown was in about the same ratio. One installation of nineteen 160 horse power engines driving compressors experienced forced shutdown due to both engines and compressors of only 0.2 to 0.3 per cent. Thus, engines are proven to be one of the most reliable sources of power. Repeat installations by concerns who have operated engines 24 hours a day for the full season is proof of the success of gas engines.

Experience has taught us that engines 20 to 30 years old will operate season after season with very small repair bills. Properly cared for and given proper replacements, engines will operate much longer, so that salvage value at the end of 20 or 25 years is considerable. Never the less, we often figure the life of an engine as 20 years, showing depreciation in the statement of overhead as inseparable from repairs. That is, an engine will depreciate much faster than it otherwise would, if adjustments and repairs are not made as needed. Therefore, allowing 20 years for the life of the engine, depreciation and repairs should be taken as 8 per cent a year.



Courtesy WESTERN GAS

Gas engines are always equipped these days with an air starting unit, so that starting is far from difficult.

The four outstanding features of improvement made in recent engines, namely, high tension ignition, forced feed oiling, throttle governing, and air starting, have so changed engine operation that modern engines are no longer comparable with old engines. Further than this, proper muffling makes operation possible even in the cities.

It is a surprise to those not acquainted with the facts to see how little is the attention required by gas engines. Frequently one man operates several plants a mile or more apart and attends to other duties, such as water company zanjero, in addition. This is possible because the fuel supply is constant, gas does not foul the engine, and the design is such as to afford safe continual operation.

For our purpose engines usually encountered may be classified as follows:

1. Slow speed engines with head and mixing box designed for gas.
2. Slow speed engines converted from liquid fuel to gas.
3. High speed engines of tractor type.

4. Automobile engines using gas as fuel.

The most economical, and in the main the most satisfactory engines are the first class. Converted engines can be made to operate fairly satisfactorily from a point of fuel economy, but conversion must be properly done. Too often this is not given attention, and only mediocre results are obtained. These engines will operate on gas as they stand, but with a high fuel consumption. Because of the fact that they have been designed to give rated power with a practical maximum of power from the fuel-air mixture at compression pressures in the neighborhood of 80 pounds per square inch the gas-air mixture is slow in burning. The explosive power of the mixture is not utilized and combustion often continues to the point of exhaust. It is therefore necessary to increase compression pressure to 100 or 110 pounds, by inserting a plate bolted either to the piston or to the inside of the head.

High speed engines will not as a rule be satisfactory on constant load, the fuel economy is not good and more constant attention, and more periodic care and repairs are required. Low first cost of course often makes it feasible to operate such engines and replace them oftener than would be necessary with heavier engines. This is true particularly of old automobile engines, picked up at small cost. However, from the standpoint of the utility they are not satisfactory. It is too easy for the owner to become tired of having to attend to such an engine and install a motor. With years of service from a heavier engine the owner is himself the utility's best protection for continued business.

IN COMPARISON with liquid fuel engines, and not here considering Diesel or semi-Diesel engines, gas at 40 cents per thousand is equal to liquid fuel at about 3.6 cents per gallon. It is apparent that gas, where available, has the engine field largely to itself.

On the average, gas engines properly installed, with air starting unit, muffler, gasometer and so on, complete and ready to operate, cost from $55.00 to $66.00 per available brake horse power. Electric motors with starting and protective devices cost in the neighborhood of $15.00 per horse power. Of course the prices per horse power vary with the size of the plant, but a comparative price of four to one may be taken as a fair average for the purpose of discussion.

In addition to first cost, a new installation may, for example, require a larger house for an engine than for a motor. Further, an engine may be chargeable with additional labor. In most cases, however, a pump must be attended to periodically, in which case

LAYKOLD
EMULSIFIED ASPHALT

THE constantly lowering water table and the always increasing demand for more and more water for irrigation purposes are unfailing indications that the water can no longer be wasted with a lavish hand.

Seepage loss from unlined ditches, the greatest wholesale waste of all, can be eliminated by the use of proper ditch lining.

Laykold is an emulsified asphalt that requires no heating, special apparatus or technical knowledge to apply. It is admirably adapted to the lining of ditches, and can be applied either in the form of asphaltic concrete or by mulching in directly to the ditch banks.

Todays Edition of a Book for 10 Years a Standard

USE OF WATER IN IRRIGATION: BY SAMUEL FORTIER; THIRD EDITION, $3.00

Introducing the first edition, (1916) the author wrote: "The volume aims to benefit three classes of readers: new settlers, irrigation farmers, and students in agricultural and engineering classes. The subject matter is confined almost exclusively to the irrigated farm and to the problems which confront the irrigator. In this respect it is an Irrigator's Handbook."

In the preface to the third edition, (1926) Dr. Fortier writes: "During the decade . . . the practice of irrigation has been much improved, the farmers' part in irrigation better understood and appreciated, and fundamental principles more fully elucidated. To record these changes aright, and to present the knowledge that has been gained, . . . it has been necessary to add a number of new articles, and to rewrite and enlarge much of what appeared in the earlier editions."

PIPE

Both USED and NEW--At a SAVING to YOU!

WHENEVER and wherever you need pipe of any size or dimension, Pacific can serve you and save you money, too. For general farm and irrigation purposes, Pacific Reconditioned Casing is a real bargain. Absolutely guaranteed. Every length straight and clean with new threads and couplings, each protected from damage in shipping by special steel protectors.

Every length rattle-tested and steam pressure-tested as proof against weakness; then dipped in a special non-tasting hot asphaltum which resists alkali and corrosion. This adds years to its life. Nowhere else in the West, except in the Pacific plant, can used pipe be so thoroughly reconditioned and then sold at such low prices.

the operator may see that the engine is functioning properly and go about his work. The proper sort of engine in this case should require no extra labor charge. In water companies, additional labor may be an item of some moment, or may be cared for by paying the present attendant a slight increase in salary, or it may amount to nothing.

It is easily seen that conditions peculiar to the individual case will determine the charges which apply. In actual work it is of primary importance that all conditions be investigated thoroughly before an engine is recommended. Otherwise an engine may be installed where it will not be satisfactory from a point of economy. In this case injury to the engine business will result far out of proportion to the importance of the particular installation causing the trouble.

COST of operating includes the following:

Fixed Charges: a—Interest, b—Depreciation, c—Repairs.

Operating Charges: a—Fuel, b—Lubrication, c—Labor.

As for interest, much has been said. The fact that the Government does not allow of charging interest on invested capital when figuring deductions from taxes should seem to support the contention that to charge interest in a statement of comparative costs is unfair. In a business the matter is quite apparent. If a man invests in his business he expects a return which will warrant that investment. Otherwise he would put his money out at interest. In other words he is being paid for his business risk and business management. In the case of an engine, the owner installs it only after he has satisfied himself that it will pay for itself in the assumed period of life, and will net a return over and above that amount. Otherwise he would better use a motor.

Therefore, since the engine is paying for itself and also netting a return, it is fair that a depreciation fund should be established. If this is not done the money is being used for something else and should be expected to be able to earn the usual interest rate at least. Hence, setting aside, on the books at least, 5 per cent of the first cost each year, and creating it with the normal interest earning power, the total interest earned for the period of the life of the engine will just equal interest charged against the engine year after year as it depreciates.

A good engine may be expected to give a thermal efficiency of about 25 per cent and a mechanical efficiency of 90 per cent. Properly designed, an engine will develop a brake horse power of 9,500 to 10,000 B.t.u. With 1000 B.t.u. gas the

(*Continued on Page 53*)

Oil Man Turns Farmer

C. F. Whittier, wealthy Californian, who recently retired from active participation in the oil industry after seventeen years as president of the United Oil Company, has purchased two sections of land at Buttonwillow, California, near Bakersfield, and will begin large-scale farming operations. Plans of development include the drilling of eight water wells immediately and the installation of a complete concrete pipe irrigation system. Cotton will be planted on the larger portion of the land at first, but it is planned to grow lettuce and other vegetables later on. The land which Mr. Whittier has purchased includes Sections 21 and 22 and is a part of the large acreage being divided and and sold by Miller & Lux.

Contends for Legal Point

J. S. Higgins, city attorney of San Diego, has expressed his opinion that it would be illegal for the city of San Diego to permit the La Mesa Irrigation District to share in the costs of the El Capitan developments and to have part of the resulting water. Attorney Higgins' contention is that the $4,500,000 bonds voted by the city were expressly for municipal purposes, and the co-operative arrangement, which has been suggested by Judge M. W. Conkling, who is trying the city's case against the La Mesa district and the Cuyamaca Water Company, would be a diversion of the funds from the purpose for which they were voted.

Must Vote Again on Bonds

Orange (California) voted $125,000 in municipal water bonds last September, but, according to the opinion of attorneys consulted by the municipality, the question must be resubmitted to the voters because of the reading of the ballot in the September election. The proposition as approved included provision for the purchase of water stock belonging to the Santa Ana Valley Irrigation Company, and because the state constitution does not permit the state or any of its political subdivisions to subscribe for stock or become a stockholder in any corporation, the attorneys hold that the whole issue is invalidated.

Dr. H. L. Kent, president of the New Mexico College of Agriculture; F. J. Rigney, of the Elephant Butte Irrigation District; and L. M. Lawson, superintendent of the Rio Grande project; have been named by Hubert Work, Secretary of the Interior, as members of a Board of Examiners to assist in the determination of the qualifications of applicants for entry to public lands on the Rio Grande Reclamation Project in New Mexico and Texas.

You *Name the* Load
We *Make the* Pipe!

SINCE concrete pipe (as made by Bent) came into its own, engineers question no longer its striking advantages for a great variety of uses. *But*—a concrete pipe installation is either a mediocre or an eminently superior job of work, depending upon who fulfilled the contract.

Many trade names have become hall-marks of tradition, that serve as an unerring guide to discriminating buyers. Today the name "BENT" on a joint of Concrete Pipe marks it as a strictly finely made product. The same care and skill is exercised in its manufacture, and in the laying of the line, as though every future contract depended on *that* job meeting the fullest requirements of specifications—*and more.*

Let us give you a "concrete" demonstration of what we mean by "Bent" Service.

WITH THE WATER COMPANIES

Of Interest Expressly to Water Works Engineers, Superintendents and General Managers

SAN FRANCISCO STARTS NEW DIVISION OF HETCH-HETCHY

By HUGH CRANE

THE FOOTHILL division of the great Hetch-Hetchy project is the next section of that titanic construction task to be undertaken by the city and county of San Francisco. The foothill division is one of the higher links in this great system that will eventually bring to San Francisco a water supply from the snows of the Sierra Nevadas sufficient for the needs of a population of four million, and will generate electrical energy estimated at 200,000 horsepower.

The highest of the ten divisions into which the project is divided is the canyon division or Lake Eleanor division, which extends from the Lake Eleanor reservoir, at 4,660 feet elevation, to Early Intake, where the aqueduct begins, at elevation 2326. The next highest division is the Mountain division, which includes the 19-mile continuous tunnel, and drops from 2326 to 2170 feet in that distance. The next division is the Moccasion division, the shortest of the ten segments of the project, but one of the most important, as the generating point for power. These three have been completed, and the next to be taken up is the Foothill Division.

THIS DIVISION extends from the Moccasin Power House, where 100,000 horsepower is developed, through the foothills a distance of 17 miles to the eastern side of the San Joaquin Valley at the Oakdale Portal. It includes 16½ miles of tunnel aqueduct and one-half mile of pressure pipe passing under the Tuolumne River and Don Pedro Reservoir. It drops from 924 feet, the elevation of the nozzles at Moccasin Power house, to 741 feet at Oakdale Portal.

Camps are now being established along the seventeen miles of the course of this division, shafts are being sunk, and the engineers in charge hope that within a month the work will be ready for bidding by contractors.

The tunnel through the Sierra foothills below Moccasin Creek for which the plans of this division call will be divided into two sections at the Tuolomne River by the Don Pedro Reservoir at Red Mountain Bar. The siphon under the reservoir is already constructed, having been completed in 1923. It is an inverted steel pipe siphon cased in concrete. This construction was not required for several years to come, but as the river channel at the crossing was to be flooded by the reservoir constructed by the irrigation districts of Turlock and Modesto, the lower portion of the siphon submerged by the lake was constructed in advance of filling the reservoir.

This section, with the ends extending well above the elevation of the dam crest, is of riveted steel pipe, 9 feet 6 inches in diameter and 771 feet long. The thickness of the steel varies from ¾ inch to 9-16 inch. The interior of the pipe is lined with cement mortar 2¼ inches in thickness, leaving the net diameter 9 feet 1½ inches. The pipe is laid on bedrock and is incased in concrete from 18 inches to 2 feet in thickness. The siphon is designed to carry the entire flow of the aqueduct of 400 million gallons per day.

A camp accommodating 100 men, and a plant including tramway, bunkers, etc., were constructed on the west side of the Tuolumne River near the crossing. Excavation was started in the main channel in November, 1922, the water being diverted by means of a cofferdam around the work. This section was rushed with all possible speed. Early fall rains hampered the work and in December, when 12,000 second feet of water passed down the river, a small section of the cofferdam was washed out. After concreting this first section of pipe, the river was turned back into its channel over the pipe and a cofferdam thrown around the east channel. No unusual difficulties were encountered on the remainder of the work and the siphon was completed and tested on June 1, 1923, in time to permit the Modesto and Turlock irrigation districts to close the gates of the Don Pedro Dam and fill the reservoir for that season's irrigation.

THE WORK now to be undertaken will add the 16½ miles of tunnel and will complete the division, marking the completion of the project from its extreme point to within 117 miles of San Francisco.

It will mark the realization of another definite step toward the eventual goal, the project which has been called the city's greatest asset, and which has been gradually evolving since the beginning of the century. Actual construction work has been going on for more than ten years. In addition to the three highest sections, the lowest part of the aqueduct, the bay crossing division, has also been completed, making the foothill section the fifth to be undertaken. Its cost is to be borne by a bond issue of $10,000,000 authorized by a vote of 20 to 1 at a special election in 1924.

San Francisco is already receiving a return from the large investments which have been made thus far, in the form of an income from the sale of power at wholesale rates near Newark, amounting to $2,000,000 a year, which pays the interest on more than $30,000,000 of the investment. This power is generated in the Moccasin division, where, under existing conditions, a delivery of more than 70,000 horsepower on an average is assured.

THE MOCCASIN division is one of the most interesting parts of the entire project. After passing through the 19-mile tunnel the water is delivered to Priest reservoir, the regulator for the Moccasin power plant. This reservoir was formed by the construction of an earth-fill dam 1,160 feet long, and 147 feet high, containing 717,283 cubic yards of earth and rock and 17,043 cubic yards of a concrete core-wall, at a cost of $1,000,000.

Water released from the reservoir passes through a concrete lined tunnel 13 feet diameter, 5,370 feet to a surge shaft 40 feet diameter, 160 feet high, from

Naturally, there are a good many local conditions that affect the choice of a pump, but there must be some reason why so many engineers insist that no matter what the TYPE of centrifugal used—it must bear the name plate of The American Well Works.

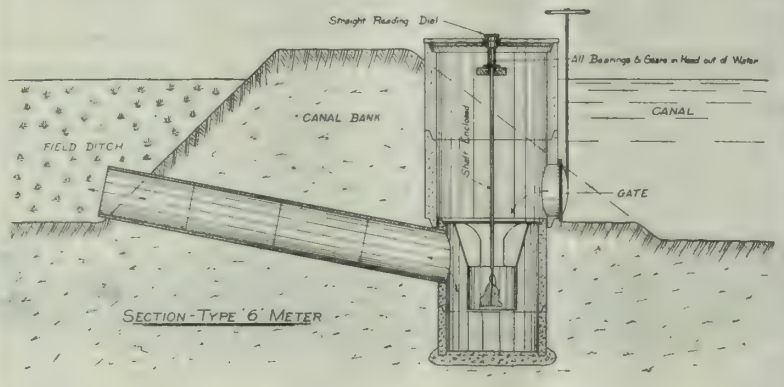
The RELIANCE METER



THE "Type 6" Reliance Irrigation Meter offers you standardized permanent construction at a very low first cost. Their sustained efficiency with a minimum of upkeep has been proven by 12 years usage. Cut shows installation of the 4 sec. ft. size in 24 and 30-inch concrete pipe. This is the standard type of setting adopted by many irrigation districts in Texas and elsewhere who are now equipping all their deliveries with this device. The "Type 6" meter is furnished in sizes ranging from ½ up to 16 sec. ft.

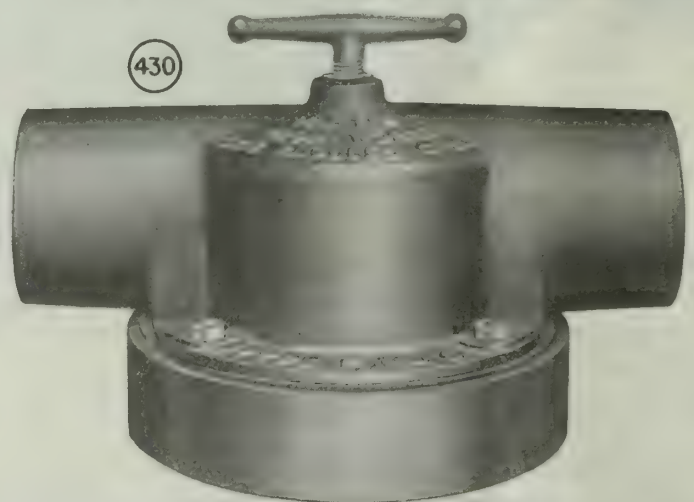
the NEW MARTIN VALVE

TYPE F—For Row-Crop Furrow Irrigation



Furrow crops such as beans, lettuce, cotton, etc., may now be irrigated most advantageously by the New MARTIN method. The Martin Valve, Type F, is attached to a concrete standpipe. Water is controlled by this valve which discharges through two outlets made to fit into standard 4-inch galvanized surface pipe. Three or four joints of surface pipe are used on each end of the valve. These surface pipes are fitted with small galvanized iron gates which control the flow of water into each furrow. Equalization of the flow to every part of the field can be attained with this improved equipment. Write us for full particulars regarding MARTIN Irrigation Appliances. Our complete catalog is now ready.

which three pipes, 104 inches diameter, lead through branch tunnels in which they are imbedded solid in concrete.

One of the pipe is capped at its tunnel portal, to be extended in future, and two of them continue on down the mountain side branching to eight nozzles which shoot solid jets of water 11 inches in diameter against the buckets of the impulse type wheels which turn the generators of the Moccasin Power House. These four machines will deliver at full load 100,000 horsepower or 80,000 kv-a.

Balancing Reservoirs

(*Continued from Page 17*)

be equal to the corresponding annual cost of operation of storage reservoirs, expressed as a percentage of the peak demand. Having found this balanced cost condition and it is deemed desirable to store water in elevated reservoirs, the pressure conditions in certain selected zones should be scrutinized and the average pressure per hour plotted, as shown on Chart "E," from which the proper elevation of stored water can be obtained.

RECORDING pressure charts are almost indispensable in the pressure survey, and should be carefully adjusted, and proper calibration maintained. I find it convenient, in a study of this kind, to determine the elevation of these gauges referred to City Datum from which the elevation of hydraulic grade at any point on the system is noted, and comparison made.

Referring to Chart "B" again, attention is directed to the hourly pressure, and a suggested method of determining the dimensions, and elevation of elevated reservoirs for this particular case. If the tank is to operate automatically, and fill from the mains during the off peak hours, and discharge during periods of large draft, then the bottom of the reservoirs should be placed at such an elevation that a reasonable pressure head will be maintained until the heavy draft has stopped, and the pressure raises in the mains to the point of filling the tank. Sufficient friction head should be allowed between the pressure head in the mains, and capacity line in the reservoir so that the tank will fill rapidly during the off peak hours. An estimate of the required friction head, can be obtained by again turning to the mass diagram. It will be noted that the lines B-B are drawn parallel and tangent to that portion of the mass diagram which indicates the night flow. The rate of flow for this period is seen to be about 12,500 g.p.m. for the two 24 hour periods studied. If reservoirs are provided in the amount of 2¼ m.g., then they also must be filled during this period which will increase the night rate of flow by the time

decided upon to fill the reservoirs. An estimate can then be made of the allowable time to fill the reservoirs from which the proper friction head can be determined.

Summary and Conclusions

That before an extensive construction program is undertaken for a city, in which the problem is one of pumping from the underground waters, and the consumption of water is relatively high, the water department would do well to make a comprehensive study of the rate of growth in the past, and forecast the future conditions which are likely to be met. Based on this study then, pumping plant sites should be selected and the distributing system so designed that balancing reservoirs of economic capacity may from time to time be added. It is believed that balancing reservoirs of suitable capacity based upon economic study can be provided to equalize the maximum hourly demands throughout the year, thereby allowing pumping plants to operate at a higher average annual load factor, resulting in better efficiency and corresponding saving in power.

Reservoirs in the form of elevated tanks, or stand pipes, are easily constructed and maintained; their economy in annual costs offer a solution in many cases, as a method to meet the peak conditions, and their adaptability to smooth out the major fluctuations in pressure is recognized. An altitude valve or other automatic device should preferably be installed in the discharge line of the tank, thereby allowing complete automatic behaviors.

Frequently a slight elevation can be found in cities, even though the general topography is assumed to be flat. In this case there is sometimes experienced some difficulty in serving consumers, particularly on the peak. This case can be treated separately, and the district isolated by means of check valves in the trunk supply lines, and storage provided sufficient to care for the demand, based on local studies, rather than the system condition. It is obvious that the check valves should be so located, and the tank at such an elevation, that flow during off peak hours will store the water and be ready for use when the next cycle of lowering of system pressure occurs.

Stored water is also an asset from the point of view of fire protection, and should be given some weight in this consideration, more so perhaps if the entire supply is being pumped, than if from a gravity source.

Regarding the aesthetics of elevated tanks and towers, it seems to me that much can be said in this respect, and the conventional design of elevated tanks and steel towers so modified as to fit in with the surrounding buildings and structures.

Section of the 20 mile 60" steel aqueduct Hetch Hetchy Water Project. This line coated inside and outside with Biturine Enamel

Lowering Pipe Upkeep

There is no better way to insure the long life of your pipe lines, assure uninterrupted service and low maintenance cost, than to let us coat them with

BITURINE ENAMEL

"The Arch Enemy of Corrosion"

with a 15 year record on underground pipe lines

We supply Biturine Enamel, furnish a competent foreman when desired, or undertake the entire work of coating under contract.

Biturine Enamel defies time, water, alkali, acids and electricity. Biturine also defies high maintenance costs. Glad to tell you more about it.

India Holds Lead in World's Irrigation Race

INDIA, popularly conceived as a backward land of tigers, turbans, and whirling dervishes, where the babies are fed periodically to the voracious Ganges, continues to hold the first place among the countries of the earth in point of irrigated acreage, as may be observed in the diagrammatic map on this page (reprinted from the NEW RECLAMATION ERA).

A steady increase of the area under irrigation in India is indicated in the Triennial Review, recently published by the Indian Department of Labor and Industries, which gives statistics on the amount of land under irrigation by government works. Figures are given for the three-year period of March 31, 1921, to March 31, 1924, and, while more than a year old in point of time covered, are the latest official calculations available.

Three quarters of a million acres were added to the area under government irrigation during the period under review, the total of lands in British India irrigated annually by government works of all kinds being 27,500,000 acres at the end of the period as compared with 26,750,000 acres during the preceding three-year period.

By years, the area irrigated totaled 27,578,308 acres in 1921-22, 28,302,303 in 1922-23, and 26,539,390 in 1923-24. In general, the results were as good as or better than those obtained the previous triennium, the notable exception being the United Provinces, where the monsoon was favorable in each of the three years. Productive works averaged 19,652,514 acres during 1921-24 as compared with 18,589,760 during 1918-21.

An interesting comparison of the acreage of crops matured during 1923-24 by means of government irrigation systems with the total area under cultivation shows that nearly 12 per cent was irrigated. The figures, by provinces, are as follows:

AREA IRRIGATED AND TOTAL AREA UNDER CULTIVATION IN 1923-24

	Net Area Cropped Acres	*Area Irrigated Acres*
Madras	36,424,000	6,891,000
Deccan	39,000,000	418,000
Sind	4,134,000	3,427,000
Bengal	22,806,000	93,000
United Provinces	35,011,000	1,979,000
Punjab	26,731,000	10,207,000
Burma	13,857,000	1,730,000
Bihar and Orissa	24,665,000	954,000
Central Provinces	17,427,000	438,000
Frontier	2,593,000	359,000
Rajputana	281,000	16,000
Baluchistan	286,000	26,000
Total	223,215,000	26,538,000

The total capital cost of government irrigation and navigation works up to the end of 1923-24 reached the enormous amount of 892,500,000 rupees (1 rupee equals $0.3666 at current exchange) yet in that year alone the value of irrigated crops was estimated at 1,400,000,000 rupees or over one and one-half times the total capital expended on the works. The percentage of area irrigated to total cropped area varied greatly in the various Provinces. Sind occupied first place with nearly 83 per cent; the Punjab came next with 38 per cent; and Madras, the Frontier Province, and Burma followed with percentages of 19, 13¾, and 12½, respectively. None of the others exceeded 10 per cent.

CONSTRUCTION of new works continued in practically all the Provinces during the triennium under review. In the Bombay Deccan the Girna River works in the Nasik collectorate were completed nad these, together with the Godavari and Pravara canals, are gradually coming into operation, while the Pravara River works and the Nira right-bank canal, incorporating respectively the Bhandardara and Lloyd (Bhatgar) Dams, are nearing completion and are already contributing to the irrigation of considerable tracts of country. Projects under consideration include the remodeling of the Mutha canals, the extension of the Gokak Canal, and a scheme for developing the Nira Valley by widening the Nira left-bank canal and constructing a new dam at Vir, to supplement the supply of water from Bhatgar. In so far as the Sind is concerned, all irrigation works have been dwarfed by the Lloyd (Sukkur) Barrage project, but a considerable number of improvements, nevertheless, have been and are still being effected. Projects for canals at Ghotki and Mahrani are under consideration.

The Riddle of the Rio Grande

(*Continued from Page 15*)

The Mexican government expressed full sympathy with the proposal, but suggested, as a counter proposal, that the scope of the commission be enlarged to include the Colorado river as well. Thus the matter stands at the present time. If the Mexican government maintains this attitude, the United States is in a helpless position, so far as the Rio Grande is concerned, for nothing can be done without the consent of Mexico. The American development on that stream will not only have to be arrested, but it will be menaced by possible development on the Mexican side.

PHYSICAL CONDITIONS favor the diversion of water on this Mexican side above the intakes of all the systems on the United States side. There is very good reason to believe that large irrigation undertakings are imminent in Mexico and it seems certain that it is a question of time only until Mexico will begin to take water out of the Rio Grande for irrigation of a portion, at least, of her valuable lands.

If this is done before additional supplies are developed by storage, it will seriously menace the present development on the American side and almost certainly cause a severe water shortage.

The users of water on the American side of the Rio Grande are not unappreciative of the fact that the interests of Mexico demand that she have water for the development of her lands—water to which she is entitled from every standpoint. They are, however, determined that their interests in the lands which have been already developed shall be protected, and are looking desperately for the solution of this problem—a solution which apparently requires an international agreement authorizing the construction of storage works.

Into this complex situation another factor has entered—a factor involving another international stream and the development of another great irrigated empire. Because of the similarity of conditions on the Rio Grande and the Colorado Rivers, the people of Texas have become intensely interested in the discussion revolving around the Colorado, and the various plans which have been put forward as the basis for its development.

In the second installment of this series of two articles, I am going to describe the conditions which link the destinies of these two rivers, and explain why the people of the lower Rio Grande Valley are vitally concerned with the plans for the proposed Boulder Canyon Dam and all-American canal.

DIGGING—CLEANING CANALS
AT LOW COST

THE NEW RUTH WITH ITS CONTINUOUS FLOW OF DIRT will dig or clean canals and trenches at a minimum cost per cubic yard or lineal foot heretofore considered impossible. The Ruth cuts continuous, even banks and smooth bottoms. Working successfully in marshy or dry ground, or canals full of water. The Ruth positively cleans the canal of all muck, sand, small willows, tules and water grasses.

Send for Bulletin No. 8—it illustrates the New Ruth Dredger; type and size of canals it will dig or clean; gives specifications, operating costs and maximum capacities.

RECLAMATION

WHAT CONSTITUTES A SUCCESSFUL COLONIZATION POLICY?

By DR. JOHN A. WIDTSOE*

Chairman, Northern Division, Board of Survey and Adjustments, Bureau of Reclamation

IN THE HISTORY of American colonization two ventures, conducted on a large scale, are of particular value in revealing the fundamental principles of successful colonization. The first of these is the settlement of the Great Basin and the Colorado River Basin by the pioneers of Utah. The second is the Federal venture in irrigation under the reclamation act of 1902.

The Utah colonization, which began in the valley of the Great Salt Lake in the summer of 1847, has spread, until settlements are now found in all the States of the Great Basin and the Colorado River Basin. Nearly all have met with unvarying success. Half a million prosperous people, two-thirds of whom are farmers, are carrying on the initial experiment of 1847. The United States Bureau of Reclamation has conducted its work in every Western State; more than 2,000,000 acres have been brought under water, and 200,000 people live on the lands reclaimed under the reclamation act. The history of those two developments should be helpful ot those who now are engaged in colonizing lands.

THESE experiences teach, first, that no enterprise in colonization can succeed unless the project is adequate to enable the farmer to meet his obligations and to live life properly in this day of high civilization. That crops can be grown is not sufficient evidence that a project is fitted for colonization.

The main question in colonization is whether the colonists, brought on the land, will remain on the land. The colonist-visitor injures a project; the colonist-settler determines its success. The test of a successful marriage is not the love of courtship days, but the love that persists after the wedding.

The experience of the Utah pioneers showed clearly that every colony placed on fertile land, with sufficient water supply, and under conditions enabling the reasonably industrious and thrifty farmer to live up to the standards of his day, was successful. When, by mischance, the people settled on infertile lands, or lands with insufficient water supply, or under adverse conditions beyond control, failure resulted.

In short, the farm must pay. Doctor Work's committee of special advisers on reclamation came to the same conclusion. Their most outstanding finding was that most Federal reclamation troubles could be traced to inherent conditions that made large areas incapable of satisfying the economic, social, and religious needs of the industrious, intelligent settler. This year's Board of Survey and Adjustments has confirmed this view by actually determining, by careful land classification, that a large proportion of Federal project lands is infertile or without water supply or unproductive for other reasons, and therefore incapable of producing crops profitably.

DR. WIDTSOE SAYS: The farmer especially must find his reward in the intangible realities. It is improbable that, in our day, the income from farming, counting the investment and labor, will be as large as in other industries. Agriculture is only in part a business; it is more a mode of living. To live in the open, to stand on one's own land, to labor independently of regulations, to match wits with nature and man; to raise one's family under conditions that breed strength of soul as well as of body—such spiritual rewards must compensate him for the lower cash income from his efforts.

The beginning of colonization wisdom is to make certain that the projects to which prospective colonists are invited are inherently capable of successful development. Projects which can not reward the farmer sufficiently to pay his obligation and to support his family in some comfort should be suspended from colonization efforts until such time as economic conditions change, or new knowledge permits a more profitable use of our resources.

A SECOND great colonization lesson taught by experience is that the prospective colonist must be selected according to his fitness to live and labor under prevailing project conditions. It takes a man of distinct gifts to become a successful farmer. In land reclamation, the farmer is the heroic figure. Capitalist and engineer must wait for their full rewards until the farmer by his unending toil has made the vision of the engineer and the dream of the banker come true. All men may love the land; but not all men can win a living from it. The margins of agricultural profits are small and the problems many and intricate.

Training in agriculture is not indispensable; it is desirable to have it. Many a city man has become a successful farmer; and, frequently, men with farm experience have failed as independent colonists. The test is, rather, love of the work and the ability to manage affairs intelligently.

The people who settled the projects of the Latter-Day Saints came from many countries. A large proportion came from industrial centers and knew little of agriculture. Nevertheless, the majority succeeded. The process of selection had secured, before they came West, a self-reliant people.

On the Federal projects all manner of men were invited to accept the new opportunities. The special advisers on reclamation found that many project troubles could be traced to the lack of selection. Men desirous of land ownership, but temperamentally or physically unfitted for the work, came on the projects only to fail.

THE third lesson taught by our colonization experience is that, though settlers are fitted for agricultural life, they must be given aid. Agriculture has become a complex art; no man can know all the facts upon which it rests. The

*An address delivered before the Conference on Reclamation and Land Settlement, Washington, D. C.

Clear Vision for the operator

A Northwest delivers full traction on both crawlers while turning as well as while going straight ahead. 100 per cent power on the turns instead of 60 per cent loss.

THE bucket is in clear view of the operator all the way, whether out beyond the boom or 20 feet down the tip of the treads.

The placing of the control levers at the very front of the operator's platform permits a clear vision for the operator. He never has to tire himself by rising to look over the platform edge to see what he is doing.

He remains in his seat with the Northwest comfortable controls at hand, and every operation in sight.

Unhandicapped, he is able to get the maximum out of the machine. Clear vision, combined with the "feather-touch" clutch control and high horsepower, assures more yardage at the end of the day.

Sit on the seat of a Northwest, grasp the controls, try their easy action—then you'll know a dragline.

Drainage and Flood Control Engineering

By G. W. PICKELS
Assistant Professor of Drainage Engineering, University of Illinois

THIS BOOK COVERS ALL PHASES OF THE DRAINAGE ENGINEER'S WORK FROM THE DRAINAGE OF SMALL AREAS OF FARM LAND BY TILE UNDERDRAINS TO THE RECLAMATION OF LARGE AREAS BY FLOOD PROTECTION, BY DRAINAGE THROUGH OPEN DITCHES AND BY PUMPING.

450 pages, 6x9, Illustrated. $4.00 Net

The marked advance in drainage practice in recent years is emphasized throughout. The sciences of hydrology, hydraulics and soil physics—particularly the results of recent researches—are satisfactorily covered from the specialized viewpoint of the drainage and flood-control engineer.

The book gives a comprehensive and well-balanced picture of drainage practice as carried on today. The economic justification of drainage and flood-control projects is set forth clearly. The legal organization of drainage districts, the essentials of drainage law, and the spreading of assessments make up a final valuable chapter.

farmer needs specialized help. The Federal and State Departments of Agriculture are making such technical aid generally available, but there is much yet to be done before every farmer can obtain necessary advice in time of need. Any plan of colonization should include provision for such aid.

The settler also requires financial aid. The man who has made a fortune elsewhere is seldom induced to become a colonist of a new project. Future colonization will be made largely with young men, ambitious for independence, but with little money. In the beginning, such men will require financial aid with which to build their houses and to equip their farms and, later, occasional help between harvests, until their growing bank accounts make further help unnecessary.

However, whether technical or financial aid is given, we must not, as a condition, compel the farmer to follow programs prepared for him. In successful agriculture, the farmer must preserve the independence of his actions; his work can not be planned for him. He must be a free agent. Nevertheless, the giving of aid, especially financial aid, enables those in charge of colonization to offer supervision and direction which the farmer usually needs, and nearly always accepts if given in the right spirit.

In the Utah settlements, the bishop and his two counselors stood at the head of a group numbering from 500 to 1,000 souls. These men were ready to assist in the material as well as in the spiritual needs of the people.

The history of the Federal reclamation projects shows without question the necessity of technical and financial aid, and that it should be given, not grudgingly but carefully, in a generous spirit. Wherever this has been done prosperity has come to the settlers.

There has come out of our settlement experiences the fourth lesson, that strong men on fertile, well watered lands and with ample aid, may fail unless they are properly organized for community life. Social are quite as important as economic needs. "Man does not live by bread alone." The colonization history of the country shows the desirability of community organization for social as well as for economic advantage.

The conditions of our day, involving many new demands, may compel future colonization enterprises to give such community organization first consideration. The value of the plan has been fully demonstrated by the Latter-Day Saints. The maintenance of a relatively small group of people, under a system of self-government, characteristic of the Mormon Church, serving the religious, economic and social needs of the people,

has contributed greatly to make the adventure in colonization successful.

The special advisers on reclamation found that community organization on the Federal irrigation projects had similar good effects. The settlers themselves had discovered it, and in many places had set about to form organized communities, out of which had grown a co-operative understanding and many successful co-operative enterprises. There can be no question about the importance of this lesson in future colonization.

Finally, a fifth lesson taught by our colonization experience is difficult to define, yet of first importance.

The success of the Mormon settlement activity, while resting upon a few simple principles, already outlined, was given life, strength, and permanence by a strong religious feeling. The things of the spirit are more important than those of the body. Spiritual forces cement the activities of mankind. Political, economic, and social forces are of secondary importance. In witness, we may recall that, in American colonization, the Church has always been utilized by those who have been most successful. Out of the communities held together by strong religious appeals, have come the leadership which has built rural America, and preserved our American institutions.

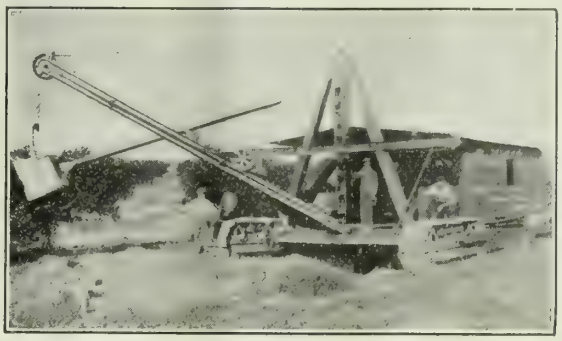
The farmer especially must find his reward in the intangible realities. It is improbable that, in our day, the income from farming, counting the investment and labor, will be as large as in other industries. Agriculture is only in part a business it is more a mode of living. To live in the open, to stand on one's own land; to labor independently of regulations; to match wits with nature and man; to raise one's family under conditions that breed strength of soul as well as of body—such spiritual rewards must compensate him for the lower cash income from his efforts.

It is doubtful if farming can ever be valued correctly on the basis of its money yield. There must be a spiritual purpose in every community, to make coherent and intelligible community activities. Life must be purposeful; else there will be no goal at which the community is aiming. Can we, of many creeds, as we continue our colonization, find an equivalent of the spiritual impulse? Can a community be made to feel the gain in the exchange of money for living? Perhaps, the best we can do is to see to it that the Church goes with the settler, so that he may be guided into visions of the great purposes of human life. However accomplished, it must be done. The acceptance of a coherent spiritual purpose in life is the most effective means of assisting a community to achieve success and happiness.

For Cleanout -- Maintenance -- New Ditches

There's a Bay City for Every Job

BAY CITY Land Dredges span the ditch, can dig any desired slope, and dump waste on both banks. BAY CITIES leave clean, wide berms, and can work up or down streams. One trip over the ditch is enough. The Shovel Type Dipper handles hard material in which other types of buckets cannot make a good showing.



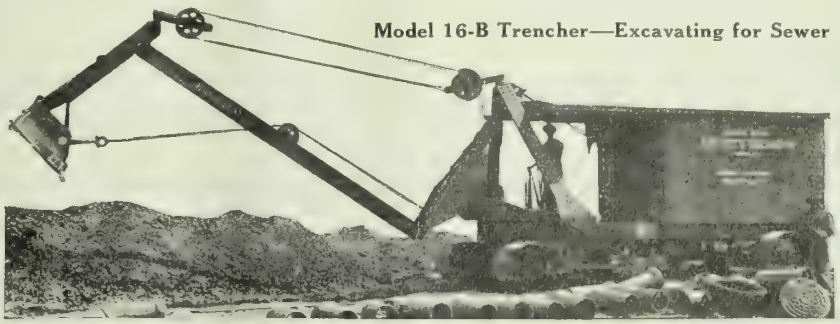
At left—One yard BAY CITY Dredge digging and cleaning ditches in Florida Citrus Groves.

BAY CITY Land Dipper Dredges are built to fit the job. Walking, Crawler, Track or Floating mounting. Easily dismantled, transported and assembled. Capacities ½ to 1½ cubic yards. Oil engine or electric operation.

FOR SMALLER DITCHES — OR PIPE LINE TRENCHES

The BAY CITY 16-B convertible Excavator will handle a wide range of work. Operates Dragline, Trench Shovel, Clamshell or Skimmer. All steel. Shipped assembled. Digs any width or depth up to 20 feet.

Model 16-B Trencher—Excavating for Sewer



or—Model 4 Excavator

BAY CITY Model 4 is a small low-priced convertible, one-man operated Excavator. Fills the gap between hand labor and high priced equipment. Capacity 20 to 40 cubic yards per hour. Gasoline or electric power. A Real Digger economically designed for the small job. Also operates shovel, and clamshell.

IRRIGATION FINANCE

HOW TO FIGURE OPERATION COSTS AND INCOME ESTIMATES

By ORA McDERMITH
Consulting Engineer, Kittitas Irrigation District

IT IS obvious that the economic success of an irrigation project depends on the success of the average individual farmer or settler who secures the benefits from the construction of the irrigation system. The economic success of the individual farmer in turn depends on whether he makes a profit by his operations. That is, the average annual gross income over a reasonable period of years must exceed the average gross expenditures necessary in carrying on such operations.

In making an estimate of the feasibility or probable opportunity it is necessary to consider items of gross income and cost of operations in the average individual case in considerable detail. The more detailed the estimate usually the less chance of error will be encountered. In the making of such an estimate it is very convenient to have the outline in diagrammatic form, working from the result desired down through the various component items which produce such result and having each item capable of being further subdivided to its furthest detail.

The amount of the "Annual gross income" will depend primarily on the volume of production and the prices secured. Estimates of crop prices, costs and conditions should be based on data obtained from similar enterprises as to past performance and corrected for local conditions and possible future influences. Such estimates should be made with clear judgment and consideration of future conditions. For instance, on the Kittitas division of the Yakima project the primary established crops are alfalfa and grain, which, combined with dairying, offer a firm foundation for an estimate of the character of crops which probably will be grown with the added water supply. Yet there are areas on this division which, on account of air, drainage, location, and soils, undoubtedly will be devoted to commercial orchards and other high-priced crops if future prices for these crops justify the investment. Influences of this character should be carefully considered in the economic estimate.

As the income from farm operations becomes available to the farmer largely at the end of the crop season we should consider first the detail of "The annual cost of operations" and following this, "The annual gross income."

Cost of land and water supply.—The primary investment of a settler on an irrigated farm unit is in the land and the water supply necessary to irrigate such land. Usually the largest investment is in the water supply. This investment may be made all in one year, or, over a long period of years. Numerous methods of financing such investment are employed and the method proposed should be carefully analyzed in order to determine its effect on the annual cost for the period covered by the economic estimate.

The cost of the land should include the initial outlay for raw, uncultivated land plus the expense necessary to put such land into condition for the production of crops.

The raw land value is for the land in its natural state and consists principally in the value for grazing purposes. This should in most cases be but a nominal figure. After the land is smoothed for the first seed bed it is considered that subsequent operations will be included under the subdivision "Cost of producing crops."

THE ITEMS under the "Cost of land," are capable of further subdivisions according to character and other conditions. For instance, the item of "Clearing" generally depends on the character of work to be performed and can be subdivided as shown in the diagram. Each of these items is capable of further subdivision if required.

The "Cost of water supply" is an added investment to the "Cost of land" to make the combination productive by the labor of the farmer. It should include all costs which are for the purpose of insuring the permanency of the water supply.

Each of these items is likewise capable of extension as in the item of "Preliminary cost" as applied to irrigation districts which should include the expense necessary to bring the project to the point of construction of the irrigation system. This is an investment to make the land more valuable.

The item "Water purchase cost" in the diagram would be the purchase price of a given quantity of water. The item "Other water rights" includes supplemental supplies of some value owned or acquired in addition to, but separate from the main supply.

Cost of improvements. — The cost of improvements should include all expenditures of the capital investment which increase the value of the farm and make it more habitable.

Further subdivision of the item "Cost of buildings" is obvious.

For convenience the "Cost of general improvements" may be further subdivided, as indicated.

Cost of equipment. — The cost of equipment includes the yearly amount expended for tools, harness, and other items necessary to enable the farmer to carry on his operations efficiently. The grouping of these items is made thus on account of the common factor of relatively large depreciation.

Cost of livestock.—The yearly cost of livestock will vary greatly. As a general proposition most of the livestock will be raised on the farm, the offspring of progenitors purchased during the first few years of operation. Other cases may occur where the purchase of livestock is relatively large each year, especially where stock is bought annually for the purpose of feeding and fattening. Further subdivision of this item is obvious.

Cost of producing crops.—The cost of producing crops is one of the largest items of the annual cost on the irrigated farm. There are many methods for estimating this cost, depending on the grouping of the component factors. The further subdivision shown is illustrative of but one combination. The items as

shown in the diagram consist of the principal operations and are capable of much more detailed subdivision.

Other current operation costs.—Under this heading will be feed purchased for stock, insurance on crops and livestock, water, operation and maintenance charges, and miscellaneous (itemized).

Personal expense. — In the farming business unlike other business enterprises the home and living expenses are considered as an integral part of the operations. These may be subdivided as indicated.

Fixed charges.—Under fixed charges we include: Insurance on buildings, interest charges, amortization, and general and personal taxes.

Miscellaneous. — Under this heading place any item which can not be placed under the above subdivisions. Any item under this heading should be accompanied with an explanation.

Annual gross income includes all receipts or values which may be received on account of any farm operation, and may be subdivided as indicated.

The completed diagram summarizes the subdivisions clearly so as to avoid duplication and the omission of important items.

Cotton Profitable on Projects

Cotton valued at $21,393,000 was grown on five Federal irrigation projects in 1925. Cotton was grown on 215,967 acres on the Salt River project, Ariz.; Yuma project, Ariz.-Calif.; Orland project, Calif.; Carlsbad project, N. Mex.; and Rio Grande project, N. Mex.-Tex.

The yield from this acreage amounted to 83,011,470 pounds of lint and 163,759,794 pounds of seed, an average of 384 pounds of lint and 712 pounds of seed per acre. The total value of the crop amounted to $21,393,218, more than 27 per cent of the total value of all crops grown on the federal irrigation projects during the year.

The value of the crop on the Salt River and Rio Grande projects amounted to more than $8,000,000 each and acreaged more than $100 an acre. For the first time cotton was grown on the Orland project in California, where 64 acres were planted as an experiment. From this acreage cotton to the value of $5,625 was grown, or an average of $87.90 an acre.

Open Riverton Lands

Twenty farm units of public land on the Pavillion Division of the Riverton (Wyoming) project of the federal Reclamation Bureau have been opened up to settlers by the Interior Department. They range in size from 35 to 108 acres. Applicants for farms must qualify before the local board of examiners as to industry, character, and health, must have had two years farm experience, and must have $2,000 in capital, or its equivalent. Charges include $1.50 per acre to cover the cost of the land, spread over three years, and one dollar per acre for two acre-feet of water, with additional water at 50 cents per acre, for the seasons of 1926, 1927 and 1928.

For Detailed Listings, Branch Offices, Etc., See the Buyers' Guide to Leading Supply Sources—Pages 55-56

MODERN Irrigation

Are *You, Too,* Profiting From the Onward March of Reclamation?

AS RECENTLY announced in these columns, the Republic of Mexico, following the lead of the United States, has passed a "Reclamation Bill" and will expend $30,000,000.00 on some twenty irrigation projects.

The Grecian government, also, taking its cue from the success of such enterprises in America, India, Egypt, Australia and elsewhere, has determined upon a comprehensive program of reclamation and irrigation in Macedonia and will spend approximately $34,000,000.00 on this work.

It is a noteworthy fact that American engineering firms have been placed in charge of both of these undertakings.

Since America (the United States) leads in the manufacture of the most modern irrigation appliances, and auxiliary equipment of every description, the major percentage of these millions will in all probability (aside from labor costs) be spent within the boundaries of the United States.

American-made drag-lines, dredges, and other excavating machinery; trucks, tractors and automobiles; cement, cement re-inforcing and other materials; pipe and pipe fittings; gates and valves; motors and motor controls; meters and other odds and ends that go to make up a fully equipped irrigation project—these will have to be provided for, and the United States is the logical source of supply.

The advertising columns of MODERN IRRIGATION are the logical source of current information regarding such equipment. Engineers and other executives, who do ordering or specifying, will find these columns during 1926 a reliable "Who's Who" of manufacturers selling the hydraulic field. Here the leading, most progressive concerns in every line will be represented.

At this moment, the pages of MODERN IRRIGATION are being examined, and examined carefully, by men whose yearly purchases in *your* line aggregate large sums of money. Long-pull advertising will help you to secure a larger percentage of this annual turnover. The men who buy are reading and studying these advertisements—never doubt it. Consciously, or unconsciously, they are forming their opinions and narrowing down their ultimate choice of equipment. Many actual decisions are made months in advance of the order for the goods.

These projects are but two of the countless many under contemplation—or actual construction—at this time. Nineteen-twenty-six will be a big year in the irrigation and allied hydraulic industries. Millions will be spent for replacements and other millions for new equipment. Are YOU making your proper bid for a share of this business? Are you represented, as an advertiser, in the columns of MODERN IRRIGATION?

If not, phone, wire or write immediately for rates and complete information. Just say: "We wish to sell more equipment this year to the hydraulic field. How can MODERN IRRIGATION help us do it? Rush full particulars."

OVERHEAD IRRIGATION

FOUR THINGS TO THINK ABOUT IN OVERHEAD SPRINKLING

Tillage of the Soil, Aeration of the Water, Clean Foliage and Frost Protection

By R. P. LEHR

IN THE February issue of MODERN IRRIGATION, *Mr. Lehr discussed three important considerations in overhead irrigation—its advantage in affording superior seepage, its adaptability to hillside irrigation, and the important matter of laying pipe for its installation. In this issue he continues the discussion, taking up four additional points which the man who uses, or is thinking of using overhead equipment should bear in mind.*

THERE is little doubt in the minds of agriculturists who are following sprinkler irrigation carefully that this new method of water handling will call for a more intensive cultivation. The furrower will be no longer necessary, but the furrower has been the means of breaking open the subsoil in a very beneficial way, when the furrows have been as deep as they should be. The change will call for more frequent use of the panbuster.

We also know that the sprinkling system will have a greater tendency to form a sole, or irrigation "pan" below the loose surface soil, than the old furrow method. We know that gravity water seeping down through the soil column carries with it the fine soil particles, which collect and compact themselves in a dense layer below the surface.

This, finally, in many soils, hinders water percolation and soil breathing of air, essential to bacterial life and chemical processes at work in the land. This is the most logical explanation we have of the so-called plow pans we often find in virgin prairie lands which have never known tillage of any kind. For this reason, we will have to make deeper use of the chisel cultivator, and for the reason that the sprinkler thoroughly wets the entire surface instead of only parts of it, some soils will experience crusting and baking at the surface when followed by conducive weather, and these factors will have to be offset by more intelligent use of cultivating implements.

THERE is one phase of overhead irrigation which I do not believe has been given due analysis. This is the special *value of aerated water*. There is an old saying among farmers that an inch of rain is worth more than an inch of irrigation water—this in spite of the fact that rain does not contain the soluble matter, which is often of beneficial character, that may be found in waters that have seeped through the soil to find their way into canals and wells.

But rain water does contain one desirable element—carbon—in the form of carbon dioxide, and in this it is unique. This may account for the benefit of rain water as compared with irrigation water. We know the value of carbon to all plant life producing a crop containing either starch or sugar, both of which are high in percentage of carbon. We also know the high percentage of carbon in the structure of the tree or plant itself.

THE SOURCE of this carbon is simply the atmosphere. Rainwater "washes" this gas out of the air to a degree depending on the size of the drop. Fine drizzle or fog is found to contain more carbon dioxide than rain drops, but will carry some carbon down to the soil from the higher air zones. From the soil it is then capable of mixing with the lower air and of being absorbed by the stomata, or breathing organs, found on the under side of leaves and in all green cell tissue, where— with the assistance of light—it is converted to starch and later to sugar in the plant chemical processes.

It may not be amiss here to say that our many classes of soil bacteria are cheifly responsible for the manufacture of this valuable gas, generated in the soil through the decay of vegetable matter by them, and the better we keep the soil aired and moistened, the better we promote the activity of these forms of bacteria. It may be true that some water will be lost through evaporation under the sprinkler system, but, in the writer's judgment, this is more than compensated by these other desirable characteristics.

An obvious result of the use of sprinklers is the fact that it keeps the foliage cleaner than other methods. The claim may be made that this results in keeping the tree foliage in better general physical condition. Grit which settles on the leaf from dust interferes with light reaching the choloroplasts, or cells where starch and sugar production reaches an important stage, for which light is essential. Nature intends that this surface be kept clean, and, except for unusual types, provides a waterproof gloss which permits foreign matter to be shed easily.

It has been pretty thoroughly demonstrated that insect pests can be substantially hindered by drenching the foliage of trees at regular intervals. I do not know how overhead sprinkling will affect propagation of mildew in crops susceptible to it. This is an item largely controlled by weather following the application of water or rainfall, and in the case of overhead irrigation, we should time our watering to fit in with favorable weather. This we cannot control in the case of rainfall.

The cherry is perhaps the chief crop that would present serious difficulty to the overhead sprinkler. When the cherry crop has advanced to a certain stage, drops of water should not be allowed to touch the fruit, for unless unusually favorable weather follows, the fruit will be injured.

THE CLAIM is often made that sprinkler irrigation is effective as a frost control measure. It is true that temperatures may be reduced by this showering of water. In fact, citrus fruit may be covered with ice by this process to a point where limbs will break. This measure will be safe as long as water is allowed to run, but it must be remembered that, if water is stopped after the ice has formed and the temperature continues to fall or to remain below the freezing point, the ice surrounding the fruit will take a temperature from the air which is even less than the freezing point of water. In other words, we would then have ice which is colder than freezing ice and this would draw upon the latent heat in the fruit until damage resulted. It is also a fact that this

system would permit a very quick means of reducing temperatures, and that the water, after reaching the soil, will fill it and this water in turn will assist in lowering temperatures by its radiation from the soil itself. Frost control is often greatly assisted by a large content of water in land irrigated previous to a freeze.

Overhead irrigation is a science so new that we have not yet learned all of its many phases. We have been at it long enough, however, to draw some fairly safe deductions and these point to its success if properly studied and applied. As the practice progresses we shall learn other lessons from it, many of them perhaps will be even more encouraging and profitable than those we have experienced in the last eight years.

Citrus Growers Discuss Water Matters at Institute

Irrigation of citrus groves provided the main theme of the annual citrus institute of Southern California growers, held at Santa Barbara in February, under the auspices of the citrus department of the Farm Bureau. Three hundred growers were in attendance.

F. H. Macpherson, widely known enthusiast for overhead irrigation, related his experiences in the use of sprinklers before the institute, discussing the benefits and limitations revealed by his investigations.

F. J. Veihmeyer, of the College of Agriculture, University of California, discussed soil water problems, asserting that losses of water by capillary rise are not as important as previously believed. Conservation of moisture by dust mulches is no longer imperative, he believes, in view of the fact that the greatest losses of water are through the transpiratory activities of plants. In this regard, the elimination of weed growth is of extreme importance. W. M. Mertz, prominent growers and investigator of Ontario, related experiences and conclusions on the efficient handling of field irrigation, his lecture being replete with practical handling of field irrigation, and suggestions on irrigation economics and efficiency.

Defeat Mokelumne District

The proposal to organize the Mokelumne River County Water District in the Lodi-Lockeford-Woodbridge-Acampo section of California was defeated by the voters in an election held March 4, by a majority of 917 to 465. The election was the result of agitation in favor of a water district for the protection of the supplies of the district from appropriation by other interests.

FORCE

Pumps, whether supplying water for oranges or cities, must be either good or bad. They either serve well or they do not serve. The force behind the ideals of Peerless engineers -- the force of the pumps themselves -- are things to depend upon. They serve well.

Peerless Pumps efficiently serve the small rancher as well as municipalities.

Peerless Pumps are made for wells 7" or larger—capacity 180 to 3000 gallons per minute. Write for our new catalog and let us help you with your irrigation problems.

Peerless Pump Company

SURVEY *of* HYDRAULIC DEVELOPMENT

As Shown by Official Records of the Month -- Local, State, and Governmental

Permits Issued

Among the more important permits to appropriate water issued by the Department of Public Works, Division of Water Rights of California, during the month of February, 1926, were the following:

Permit No 2414, Application No. 3895 (Eldorado County) Issued to Tahoe Electric Power Co., c/o E. D. N. Lehe, Sacramento, Calif., February 9, 1926, for 320 acre feet per annum from Star Lake in Sec. 30, T 12 N, R 19 E. Sec. 11, T 12 N, R 18 E. for power purposes in Sec. 11, T 12 N, R 18 E. Proposes to develop 357 T. H. P. Estimated cost $2,000.00.

Permit No 2416, Application No. 4573 (Tulare County) Issued to San Joaquin Light & Power Corp., Fresno, Calif., February 11, 1926, for 6 cubic foot per second from Wilson Creek and Morehouse Creek Springs in Sec. 32, T 20 S, R 31 E. and Sec. 30, T 20 S, R 31 E. for power purposes in Sec. 22, T 20 S, R 30 E. 1049 T. H. P. to be developed Estimated cost $11,500.00.

Permit No 2417, Application No. 3712 (San Bernardino County) Issued to Wm. Erwin, Pine Knot, Calif., February 11, 1926, for 0.05 cubic foot per second from Lone Mountain Spring in Sec. 31, T 2 N, R 2 E. for domestic use in Sec. 20. Estimated cost $5,000.00.

Permit No. 2418, Application No. 4009 (San Bernardino County) Issued to Big Bear Realty Corp., Los Angeles, Calif., February 11, 1926, for 0.025 cubic foot per second from unnamed spring in Sec. 31, T 2 N, R 2 E. for domestic use in Sec. 24, T 2 N, R 1 E. Estimated cost $10,000.00.

Permit No. 2419, Application No. 4385 (Sacramento County) Issued to North Sacramento Land Co., Sacramento, Calif., February 15, 1926, for 8 cubic foot per second from American River in Sec. 32, T 9 N, R 5 E. for use for irrigation of 640 acres near point of diversion. Estimated cost $15,000.00.

Permit No. 2420, Application No. 4836 (Sacramento County) Issued to North Sacramento Light & Water Co., Sacramento, Calif., February 15, 1926, for 12.4 cubic foot per second from American River in Sec. 32, T 9 N, R 5 E. for municipal purposes in North Sacramento and suburbs. Estimated cost $25,000.00.

Permit No. 2421, Application No. 4387 (Stanislaus County) Issued to Charles F. and Lottie B. Rose of Empire, Calif., February 15, 1926, for 0.25 cubic foot per second from Tuolumne River in Sec. 6, T 4 S, R 10 E. for irrigation of 20 acres in Sec. 6. Estimated cost $1,000.00.

Permit No. 2422, Application No. 4555 Modoc County) Issued to John A. Kresage, Adin, Calif., February 16, 1926, for 1.01 cubic feet per second from Ash Creek in Sec. 22, T 39 N, R 9 E, for use for irrigation of 91 acres near point of diversion. Estimated cost $750.00.

Permit No. 2424, Application No. 4755 (Siskiyou County) Issued to D. G. Weisz of Happy Camp, Calif., February 17, 1926, for 0.45 cubic foot per second from Bear Creek in Sec. 33, T 15 N, R 8 E, for irrigation of 36.05 acres near point of diversion. Estimated cost $600.00.

Permit No. 2425, Application No. 4584 (Inyo County) Issued to Paul N. Nunn etc., Deep Springs, Calif., February 19, 1926, for 10 cubic foot per second from Deep Spring, Buckhorn Spring and 32 other springs in Sec. 3, 9, 16, T 8 S, R 36 E. and Sec. 32 and 33, T 7 S, R 36 E. for irrigation of 1560 acres and stockwatering near points of diversion. Estimated cost $15,000.00.

Permit 2426, Application No. 4682 (Inyo County) Issued to Burchard Fine of Coso Junction, Calif., February 19, 1926, for 1.0 cubic foot per second from East Sacatar Creek in Sec. 21, T 22 S, R 37 E, for irrigation of 120 acres and domestic use near point of diversion. Estimated cost $800.00.

Permit No. 2428, Application No. 4832 (Mendocino County) Issued to Agnes C. Thomas of Ukiah, Calif., February 23, 1926, for 0.99 cubic foot per second from Russian River in Sec. 16, T 15 N, R 12 W, for irrigation of 79.24 acres near point of diversion.

Permit No. 2431, Application No. 4412 (Lassen County) Issued to J. J. Fleming, Wendel, Calif., February 25, 1926, for 4500 acre feet per annum from Secret Valley Creek in Sec. 36, T 31 N, R 14 E, for irrigation of 2033 acres near point of diversion. Estimated cost $6,600.00.

Permit No. 2434, Application No. 4820 (San Joaquin County) Issued to Walter A. Perry, Stockton, Calif., February 27, 1926, for 2.53 cubic foot per second from Old River in Sec. 29, T 1 S, R 6 E. for irrigation of 203 acres near point of diversion. Estimated cost $4,000.00.

Applications Filed

Among the applications for permit to appropriate water filed with the State Department of Public Works, Division of Water Rights, (California) during the month of February were the following:

Application No. 4908 (Yolo County) Chas. S. Luce, Box 155, Sacramento, Calif. for 2.86 cubic foot per second from Sacramento River, tributary to Suisun Bay. To be diverted in Sec. 1, T 10 N, R 3 E, M. D. M. for irrigation purposes on 229.1 acres. Estimated cost $3,500.00.

Application No. 4909 (Siskiyou County) Montague Irrigation District, Box 275, Montague, Calif. for 5 cubic feet per second from Little Shasta River, tributary to Shasta River. To be diverted in Sec. 26, T 45 N, R 5 W M. D. M. for municipal purposes in City of Montague. Estimated cost $8,000.00.

Application No. 4911 (Butte County) Charles Bloom, Box 69, Richvale, Calif. for 2.65 cubic feet per second from ditch "B" of Drainage Dist. No. 200, tributary to Sacramento River via Butte Creek. To be diverted in Sec. 22, T 19 N, R 2 E. M.D.M. for irrigation of 105.9 acres of rice in Sec. 22, T 19 N, R 2 E M.D.M. Estimated cost $1,000.00.

Application No. 4912 (Siskiyou County) Montague Irrigation District, Box 275, Montague, Calif., for 50 cubic foot per second from Little Shasta River tributary to Shasta River. To be diverted in Sec. 26, T 45 N, R 5 W, M.D.M. for irrigation purposes on 15,000 acres in Montague Irrigation District. Estimated cost $300.00.

Application No. 4913 (Humboldt County) James Marshall, c/o C. W. Rastall, Supt. Hoopa Valley Agency and school, Hoopa, Calif., for .45 cubic foot per second from Hostler Creek, tributary to Trinity River. To be diverted in Sec. 13, T 8 N, R 5 E. H. M. for irrigation purposes on 36 acres on Sec. 14, T 8 N, R 5 E. H. M. Estimated cost $1,000.00.

Application No. 4916 (Yuba County) Yuba River Power Co., 235 Standard Oil Bldg., San Francisco, Calif., for 15,000 acre feet per annum from North Fork Yuba River, tributary to Feather River. To be diverted in Sec. 24, T 18 N, R 7 E. M. D. M. and Sec. 22, T 16 N, R 6 E. M. D. M. for irrigation and domestic purposes.

Application No. 4919 (San Joaquin County) D. Muller c/o Ohm & Raab, 517 E. Market Street, Stockton, Calif. for 0.25 cubic foot per second from Middle River, tributary to San Joaquin River. To be diverted in Sec. 35, T 1 N, R 5 E. M. D. M. for irrigation purposes on 20 acres in Sec. 35, T 1 N, R 5 E. Estimated cost $700.00.

Application No. 4921 (San Joaquin County) M. Bronich c/o Ohm & Raab, 517 E. Market Street, Stockton, Calif., for 2.99 cubic foot per second from Old River, tributary to San Joaquin River. To be diverted in Sec. 33, T 1 S, R 5 E. M. D. M. for irrigation purposes on 239.8 acres in Secs. 28, 29, 32 and 33, T 1 S, R 5 E. M. D. M. Estimated cost $2,000.00.

Application No. 4922 (San Joaquin County) D. Muller c/o Ohm & Raab, 517 E. Market Street, Stockton, Calif., for 2.15 cubic foot per second from San Joaquin River, tributary to Suisun Bay. To be diverted in Sec. 21, T 1 N, R 6 E. M. D. M. for irrigation purposes on 17.1 acres in Sec. 21, T 1 N, R 6 E. M. D. M. Estimated cost $2,500.00.

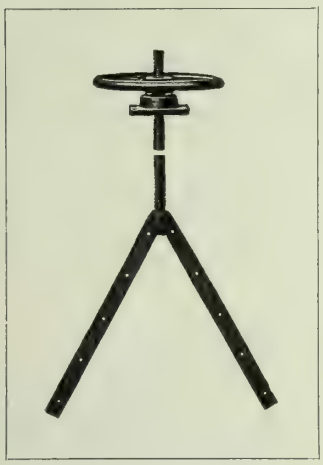
Application No. 4923 (Del Norte County) C. Romander c/o James Davis, Dist. Attorney, Crescent City, Calif., for 300 cubic foot per second from South Fk. Smith River, tributary to Smith River. To be diverted in Sec. 11, T 16 N, R 1 E. H. M. for power purposes in Sec. 10, T 16 N, R 1 E. H. M. for 3750 H. P. Estimated cost $300,000.00.

Application No. 4925 (Riverside County) Ross H. McDill c/o Frank C. Prescott, Atty., 145 S. Broadway, Los Angeles, Calif., for 1½ cubic foot per second from Cushawala Can-

·SNOW·

IRRIGATION APPLIANCES

The Snow Standard Hand Wheel Gate Raising Devices



The cut at the left illustrates the form ordinarily used with wooden canal and head gates. The screw is of steel with machine cut thread working through a bronze nut. The hand wheel, stem and screw are furnished in a variety of sizes with any desired length of thread. The Y straps may be of any length and with any desired spread. Built to fit your particular job.

The illustration at the right shows the ball-bearing device with Type C standard ordinarily used for the heavier lifts. As with the simpler device above, this is also furnished in a variety of sizes to fit your requirements. Back-gearing can be furnished for excessive lifts.

Both devices are exceptionally well built, efficient and moderately priced

PIPE

—another year coming

Work interrupted . . time lost . . if your delays were due to faulty irrigation pipe replace it with Montague.

For 75 years Montague has been making satisf ctory steel products. Montague pipe is designed for you to lay—and forget!

Don't take chances this year with unknown piping—insist on Montague—the "pipe-name" that means service. Special catalog sent free on request. Write for it.

Montague Well Casing.....5-A
Riveted Steel Pipe.....5-B
Surface Irrigation Pipe.....5-C

We also make a full line of Oil and Water Tanks—Siphons—Stacks and Steel Flumes. Prices sent upon application.

MONTAGUE PIPE & STEEL CO

San Francisco California

More than just a stopping place; a central point from which you enjoy most thoroughly all San Francisco's attractions—the beautiful Plaza overlooking Union Square.

SAN FRANCISCO

yon, tributary to Thousand Palm Wash and Whitewater River watershed. To be diverted in Sec. 18, T 4 S, R 7 E. S. B. M. for irrigation and domestic purposes on 167.34 acres in Sec. 30, T 4 S, R 7 E. S. B. M.

Application No. 4926 (Nevada County) Jonas Hirsch, Overland Hotel, Reno, Nevada, for .37 cubic foot per second from Juniper Creek, tributary to Truckee River. To be diverted in Sec. 34, T 18 N, R 17 E. M. D. M. for irrigation and domestic purposes on 30 acres in Sec 34, T 18 N, R 17 E. M. D. M. Estimated cost $2,000.00.

Application No. 4929 (San Diego County) La Mesa, Lemon Grove and Spring Valley Irrigation Dist. Attention T. H. King, 121 S. Spring St., La Mesa, Calif., for 50 cubic foot per second and 18,000 acre feet per annum from Santa Ysabel Creek, tributary to San Dieguito River. To be diverted in Sec. 19, T 12 S, R 3 E. S. B. M. for irrigation and domestic purposes on 18,000 acres in District.

Application No. 4931 (San Bernardino County) Lead Mining Co. c/o E. H. Hughes, Mgr. P. O. Box 193, Trona, Calif., for .005 cubic foot per second from 6 unnamed springs, tributary to Thompson Canyon and Panamint Valley. To be diverted in Sec. 17, T 20 S, R 42 E. M. D. M. for mining and domestic purposes in Sec. 2, T 20 S, R 42 E. M. D. M. for mining and domestic purposes in Sec. 2, T 20 S, R 42 E. M. D. M. Estimated cost $3,000.00.

Application No. 4933 (Inyo County) American Trona Corporation, R. K. Oberteuffer, Trona, Calif., for .0198 cubic foot per second from Rattlesnake Spring, tributary to Searles Lake. To be diverted in Sec. 2, T 24 S, R 42 E. M. D. M. for mining and domestic purposes in Secs. 17, 22, 28, T 24 S, R 43 E. Estimated cost $2,000.00.

Application No. 4934 (Inyo County) American Trona Corp., R. K. Oberteuffer, Trona, Calif. for .0226 cubic foot per second from Argus Spring, tributary to Searles Lake. To be diverted in Sec. 10, T 24 S, R 42 E. M. D. M. for mining and domestic purposes in Sec. 17, 22, 28, T 25 S, R 43 E. M. D. M. Estimated cost $3,000.00.

OREGON

Among the more important applications for permit to appropriate water filed in the office of Rhea Luper, state engineer of Oregon, during February were the following:

Henry George Alois Steger of Merlin, covering the appropriation of water from a small spring for irrigation of 20 acres in Josephine County, at a cost of $300.

J. D. Agee of Grants Pass, covering the appropriation of water from an unnamed stream for irrigation of 20 acres in Josephine County, at a cost of $500.

Mrs. Adda M. DeWitt of Austin, covering the appropriation of water from Big Butte Creek for development of 25 theoretical horsepower in Grant County, at a cost of $200.

C. E. Walker and Wallace H. Edson of Tillamook, covering the appropriation of water from Munson Creek for irrigation of 35 acres in Tillamook County, at a cost of $500.

Benton Carter of Long Creek, covering the appropriation of water from Pole and Gander Creeks for irrigation of 32 acres in Grant County, at a cost of $600.

Louis C. Schafer of Central Point, covering the appropriation of water from Rogue River for irrigation of 4 acres in Jackson County, at a cost of $4,800.

J. H. Eubanks of Wamic, covering the appropriation of water from Three Mile Creek for irrigation of 5 acres in Wasco County.

W. M. Smith of Hood River, covering the appropriation of water from an unnamed spring for irrigation purposes in Hood River County.

D. L. Ebbert of Aurora, covering the appropriation of water from Molalla River for irrigation of 50 acres in Clackamas County.

First Congregational Church of Forest Grove, covering the appropriation of water from Gales Creek for irrigation of 9.276 acres in Washington County, at a cost of $1200.

George W. Bates of Portland, covering the appropriation of water from Johnson Creek for irrigation of 80 acres in Multnomah County.

T. W. Penn of Ontario, covering the appropriation of waste water from Berthold Ranch for supplemental irrigation of 50 acres in Malheur County.

Carl F. Uhden, Ernest B. Hussey, James B. Dodge, and Kenneth G. Harlan of Seattle, Washington, covering the construction of Bear Reservoir and Elbow Reservoir for storage of approximately 40,000 acre feet for irrigation and power purposes in Umatilla County. (Water to be appropriated from Walla Walla River).

R. D. Butler of Junction City, covering the appropriation of water from Amazon Slough for irrigation of 80 acres in Lane County.

Would Sell $50,000 Bonds

The Hermosa-Redondo Water Company has applied to the Railroad Commission for authority to issue and sell at no less than 95 and accrued interest, $50,000 face value of its Series B, six per cent, sinking fund, first mortgage gold bonds, due December 1, 1955; and also to issue and sell at not less than 91, $37,000 of its seven per cent cumulative preferred stock, and $26,500 of its common stock, and for a readjustment of its rates to provide a sufficient income to permit the carrying out of a construction program aggregating in excess of $100,000.

Dam Cost to Date $800,000

A report issued during February shows that the South San Joaquin and Oakdale Irrigation districts have already expended almost $800,000 on the Melones Dam, the total cost of which, with rights of way, is eventually expected to reach more than $2,000,000. Expenditures on the Melones railway aggregated $289,593.25. Of this amount $37,304.10 went for rails, $25,660.75 for ties, and $44,475.39 for equipment. Cost of the road into the dam amounted to $14,685.86. Dam and reservoir accounted for $464,878.31. This included also the rights of way. Other items are: $12,000 for diversion of water river; $83,728 for work on the foundation and $14,411.58 for concrete.

Advocates Gas for Power

(*Continued from Page 33*)

consumption will be 10 cubic feet per brake horse power hour; with 500 B.t.u. gas, 20 cubic feet, and so on until the gas content lowers to about 150 B.t.u.

A slow speed engine properly designed and properly operated will consume one gallon of oil costing from 20 to 35 cents per gallon, for each three thousand or more horse power hours of operation. Other engines may use a gallon for each 750 horse power hours.

An electric motor may be assumed to operate with an efficiency of about 90 per cent under good conditions. An engine will vary from the above stated 9,500 B.t.u. according to the load. The fuel consumption efficiency should be about 98 per cent at 87.5 per cent load; 95.7 per cent at 75 per cent load and 90 per cent at 62.5 per cent load. Of course the speed of an engine may be decreased in proportion to the load and thus retain nearly the same efficiency as at full load. This is true within reasonable limits. In fact the flexibility of an engine is one of its most desirable features.

IN THE construction of the graph (Page thirty) showing comparative costs it was assumed that an engine would be sized 10 per cent greater than the load while a motor would be the same as the load. The following rates were used:

Gas

First 200M per month per meter at	$0.55 per M
Next 300	.50
Over 500	.30

Minimum $96.00 per year.

Electric

	Rate per kwh for connected loads				
	1 hp to 4 hp	5 hp to 14 hp	15 hp to 49 hp	50 hp to 99 hp	100 hp and over
First 400 kwh per hp	3.2c	2.7c	2.5c	2.3c	2.3c
Next 600	1.8	1.5	1.4	1.3	1.2
Over 1000	1.2	1.1	1.0	0.95	0.9
Minimum per hp per yr.	$9.00	$8.00	$7.50	$7.25	$7.00

but not less than $15.00 per year.

The item of interest was omitted, and labor charges were considered to be offset.

The point of equal cost for a 25 H.P. load is 286 hours. For 50 H.P. load operating 400 hours per month the point of equal cost is 322 hours. The same load operating full time reaches equal cost at 316 hours. A 100 H.P. load operating 200 hours a month reaches equal cost at 343 hours; operating 500 hours a month, at 355 hours, and operating 730 hours a month, at 317 hours. A 200 H.P. load operating full time reaches equal cost at 301 hours. From this it may be seen that a 200 H.P. load operating full time reaches equal cost later than does a 25 H.P. load operating only 286 hours or operating full time. This is because the two rates have no relation to each other in their decrease due to increased consumption. It will also be observed that a 200 H.P. engine load will operate for comparatively little more than a 100 H.P. motor load.

Under many loads an engine will pay for itself in from two to four years. A test was made in one plant to show comparative operating costs. An engine and a motor were so placed that the same pump belt could be used from the motor or from the engine jack shaft. The test was made with motor for 24 hours and the engine for 24 hours, a few days apart. Rates were arrived at from average rates actually charged at the plant. The following results were obtained:

Electric

Average rate	1.129c per kwh
Consumption per hour inch	800.5 watts
Energy charge per hour inch	0.904c

Gas

Average rate	35.63c per M
Consumption per hour inch	9.92 cubic feet
Gas costs per hour inch	0.353c
Oil—Shell Red Extra Heavy @26c a gallon, using 3¼ gals. in 24 hrs.; oil cost per hour inch	0.023c
Labor	No extra labor required
Total engine operation:	
Gas	0.353c
Oil	0.023c
Total	0.376c

Conclusion

Total gas costs	376
Total electric costs	904
	41.5%

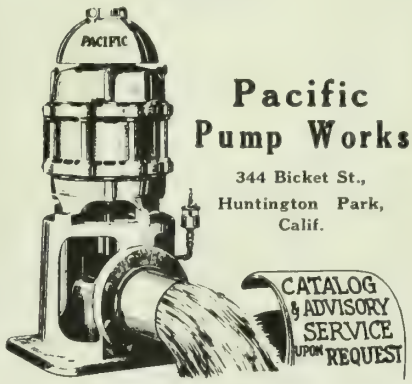
As stated above an engine will develop a brake H.P.H. on about 10,000 B.t.u. in the gas. With 500 B.t.u gas the cost, at 40c per thousand cubic feet would be 0.8c per H.P.H. instead of 0.4c, as obtained before. This means that in only rare cases where gas and electric rates afford considerable margin would engines be installed. With mixed gas containing 850 B.t.u. the cost per H.P.H. at the same rate would be about 0.47c, which retains sufficient margin to afford economical engine operation in a number of cases.

Smooth as Velvet

COMPACT SINGLE-UNIT, PERFECTLY ALIGNED, "SMOOTH AS VELVET" OPERATION ARE FEATURES OF

PACIFIC PUMPS

All parts easily accessible; motor of 7½ to 50 h. p. interchangeable on same head—economical, efficient. Investigate.



Pacific Pump Works

344 Bicket St.,
Huntington Park,
Calif.

IT'S THE *BOTTOM OF THE WELL* THAT COUNTS!

A great NEW principle for pumping water has been evolved. The advantages of the air-lift have long been recognized.
The idea of an air-driven turbine *pump*, however, combining every advantage of the ordinary air-lift—with its marked economies of cost and upkeep—is now a practical reality. No more sand troubles—no more expensive repairs and shutdowns. All parts requiring attention or repair are *on the surface*. Cut at left tells the story. Agents wanted in open territory. Send for literature.

AMONG OUR CONTRIBUTORS

Editorial Jottings About Current and Forthcoming Feature Articles, Dealing With Practical Problems of Hydraulics, and the Men Who Have Written Them

CONTRIBUTORS to this issue represent many different phases of irrigation and hydraulic endeavor, from the purely agricultural interest of the leading article, to the specialized appeals of the departmental material. The official heads of all hydraulic developments of two states are included; two of the men whose work is in this issue are known everywhere for their eminence in the institutional development of irrigation and reclamation practice; several are practicing engineers in one or another division of water work; and one article is of special interest to those who follow the legal progress of the industry.

DONALD MITCHELL, whose official connection is with the Deglet Noor Date Growers' Association, Indio, California, has written an article which will prove of consummate interest to irrigationists from many points of view. Here is a perfect example of how irrigation extends not only the amount, but the variety of food production, how it brings under cultivation new areas without increasing the competition which older farm lands must face; how it creates new crops, new demands, and a new industry, for large social and economic gains. Mr. Mitchell has been engaged in the packing and marketing of tropical and semi-tropical fruits for the whole of his professional life-time, although his identification with the date industry is comparatively recent. He is a graduate of the University of Redlands (California), served with the American air forces in France in 1917, and since his return to the United States has been engaged in the fruit industry in Southern California.

W. W. MCLAUGHLIN is known throughout the irrigation country. He is now associate chief of the Division of Agricultural Engineering of the Bureau of Public Roads of the U. S. Department of Agriculture. He would have accomplished a real service for the readers of MODERN IRRIGATION if he had done nothing more, in his article in this issue, than to show why and how the admirable organization with which he is connected has developed so long and polyliteral a name. But, of course, he does much more than that. His article is taken from the first part of an address which he made in February before the annual meeting of the Idaho Irrigation Congress at Pocatello, and is an admirable exposition of the evolution of the work of this important government institution which has kept pace with the growth in the extent and complexity of irrigation's many problems. Mr. McLaughlin is at the head of the irrigation activities of the Division, and shares the title of Chief of the Division with S. H. McCrory, who heads its drainage investigations. Mr. McLaughlin's headquarters are at Berkeley, California.

C. H. PEASE, who writes on "The Riddle of the Rio Grande," is secretary of an organization of water users in the lower Rio Grande Valley, Texas, and is also editor of the *Gravity Irrigation News*, a weekly newspaper published in McAllen, Texas, serving the people of that community and the surrounding district with special emphasis upon the underlying and basic common interest which unites them—the water supply that has made this section a productive agricultural area. In writing about the problem of the Rio Grande and the division of its water supply Mr. Pease is discussing a problem which is much more than academic. It is one that his entire section recognizes as poignantly and immediately important. Mr. Pease is at present on the Pacific Coast, spending the winter at Berkeley, California.

EDMUND K. BARNUM is chief engineer of the Fresno City Water Corporation, Fresno, California. Fresno, while not as well known as several of the coast cities of California, is one of the metropolitan centers of the west, and Mr. Barnum, by his technical work in connection with the problems of its domestic water supply, is making a real contribution to the development of water works practice on the Pacific Coast. His article gives the results of studies which he has made in the important problem of meeting the peak demand of a water supply system by an auxiliary supply. It was presented to a recent meeting of the California Section of the American Water Works Association.

WARREN G. SWENDSEN is a leader of hydraulic development in the northwest, although his experience has extended to practically every part of the continent where irrigation and drainage are largely practiced. As commissioner of reclamation of Idaho, he has become conversant with all phases of the water problems of that commonwealth, and occupies an exceptional position, from which, with incontrovertible authority, he can discuss the matters with which he deals in this article, taken from his annual address as president of the Idaho Irrigation Congress, at its meeting in February. An outline of Mr. Swendsen's professional career appeared in the February number of MODERN IRRIGATION, in which he was introduced as a member of the magazine's Board of Editorial Advisors.

M. C. HINDERLIDER is State Engineer of Colorado, which state ranks second among the American commonwealths in point of irrigated acreage. Mr. Hinderlider was educated in the middle west, gained his earlier experience in government work which took him into seven western states in charge of hydrographic surveys, has done a large amount of work in the design and construction of hydro-electric plants and irrigation works in Colorado, New Mexico and Arizona, and has been state engineer of Colorado since 1923. Among the large works with the construction of which he has been connected are the hydro power plant of the Central Colorado Power Company on the Colorado River at Glenwood Springs, hydro power pumping plants of the Orchard Mesa and Redlands Companies at Grand Junction —the largest pumping plant in Colorado—the Beaver Park masonry dam, the Terrace Dam and the dam across the Colorado near Grand Junction. He has had twenty-five years of varied experience in investigations and reports involving the study and analysis of water supplies, and the utilization of valuation of such supplies for irrigation, power and municipal uses. (See Frontispiece.)

HANKINS & HANKINS, who have prepared the article on recent decisions from western courts involving questions of irrigation law, are well known attorneys of San Francisco. They will conduct a department, in future issues of the magazine, devoted to this important subject.

N. C. GROVER is chief hydraulic engineer of the United States Geological Survey, and his paper represents an interesting analysis of the part played by this useful government institution, which is constructively contributing to the development of hydraulics.

F. M. BANKS is supervisor of sales for the Southern Counties Gas Company, at Los Angeles. His article on the costs of gas is an abbreviated presentation of a lecture, prepared not for the consumer of gas, but for the vendors of gas engines and of the fuel. Only that part of his remarks which seemed to contain information usefully applicable to the pumper of irrigation water was selected for inclusion in this article, but even in this excerption the reader will notice that the author is speaking primarily to his own industry rather than to the irrigation reader. His analysis of the costs of gas and his comparison of gas with other fuels is nevertheless of real interest to irrigators, especially in Southern California, where the gas engine is extensively used.

JOHN A. WIDTSOE is one of the "big" men of reclamation. His article on the five essentials of a successful policy of colonization is interesting not alone for its compressed wisdom, but for the fact that it approaches the problem from a standpoint very different from the ordinary. Dr. Widtsoe is eminent in the Mormon church, and he naturally refers to the experience of the Mormon pioneers of irrigation for much of the illustrative matter of his article. On account of this concern, also, he emphasizes the part that the spiritual and religious elements of settlement play in successful reclamation. As chairman of the northern board of survey and adjustments he has had ample opportunity to contact with the successes, the failures, and the near failures of settlement attempts, and he speaks from the standpoint of many years devoted to the study and practice of reclamation.

J. O. QUILLER and HUGH CRANE are staff contributors. ORA MCDERMITH is consulting engineer of the Kittitas Reclamation District, Washington. For his article acknowledgements are due to the *New Reclamation Era*. R. P. LEHR is connected with the Killefer Manufacturing Company, Los Angeles, and has contributed articles on overhead irrigation to previous issues.

TABLE OF CONTENTS

For APRIL, 1926

THE PROGRESS OF IRRIGATION—A BRIEF SURVEY OF THE IRRIGATION HORIZON 9

GENERAL FEATURES

FRONTISPIECE—*Hon. C. C. Moore, Governor of Idaho* 8

WHOSE WATER? ..... By Gordon Zander 11
Associate Hydraulic Engineer of the California Division of Water Rights Tells How the Troublesome Question of Water Titles is Handled in his State.

IRRIGATION DISTRICTS IN ANNUAL MEETING 13
California Association Inspects Great Exchequer Dam and Enjoys Constructive Business Session as Guests of Merced District.

HOW DRAINAGE PAYS THE FARMER ..... By S. H. McCrory 14
The Profits of a Farm Often Depend Directly on the Drainage Provisions, Says the Chief of the Drainage Investigations of the Department of Agriculture.

PIPE CORROSION—CAUSES AND PREVENTION ..... By Dozier Finley 16
Method of Covering Pipe With Bituminous Protective Layer Described as Possible Remedy for the Destructive and Expensive Menace of Underground Corrosion.

TWO RIVERS OF DOUBT ..... By C. H. Pease 18
The Rio Grande and the Colorado Are International Streams Whose Destinies Are Strangely Clouded With Uncertainty and Interlinked One With the Other.

WHAT IRRIGATION HAS DONE FOR MY STATE—UTAH ..... By O. W. Israelsen 19
Irrigation Has Literally Made Utah Possible, Says Dr. Israelsen, Whose Prominence in Water Development Makes Him a Most Competent Witness.

KEEPING UP WITH IRRIGATION ..... By W. W. McLaughlin 22
Associate Chief of the Division of Agricultural Engineering Looks Into the Future of Reclamation and Points Out the Fields Which Demand First Attention.

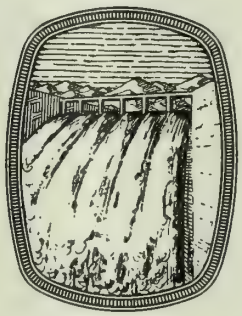
PETROLEUM WORLD 626 S. SPRING ST., LOS ANGELES, CALIF. MODERN IRRIGATION

HON. C. C. MOORE

Governor of the State of Idaho, who, during March, led a delegation of influential business men on a trade mission to Southern California in the interest of closer commercial relations between the northwest and the southwest. Governor Moore is an ardent supporter of irrigation, and, during his California sojourn, took occasion to testify to his great confidence in the future prosperity of the whole Western United States under a program of expanding irrigation.

MODERN Irrigation
The Magazine of Applied Hydraulics



Volume II APRIL, 1926 Number 4

The Progress *of* Irrigation

FLOOD CONTROL work in Southern California suffered severe damages in the early April flood resulting from torrential rain storms that were general over the south Pacific Coast area, sweeping in from the sea and proceeding eastward over Utah and Nevada. At Pacoima, where Los Angeles County is constructing a flood control dam which will be the highest structure of the kind in the world, with a height of 375 feet above streambed, the construction works of Bent Brothers, who are the contractors on the job, were covered with debris, and the excavation, which was progressing rapidly toward completion, was refilled twenty-five feet with rock and gravel. The work on this dam will be delayed a month as the result of the damage sustained.

The Puddingstone dam, another flood-control structure, near San Dimas, California, gave way under the accumulation of water and released more than 300 acre-feet of water, doing considerable damage to homes and orchards below. This construction was of a temporary nature, only a portion of the concrete foundation for the dam having been completed. Ultimately it is to be an earth dam, and 100 feet of its foundation was undermined and washed out in the storm.

The damage sustained in Southern California and elsewhere, however, was for the most part forgotten in the general rejoicing over the much-needed and very generous rainfall, which exceeded recorded storms for April at many points, and dissipated the fear which remained, after a rainless March, that a "dry year" might still menace the water supply of the coming summer.

At Los Angeles, the seasonal rainfall was brought to a point slightly in excess of the normal seasonal total of 14.23 inches. At Riverside, April storms gave a season total of more than twice the total rainfall of 1925. As MODERN IRRIGATION went to press, more storms were predicted by the U. S. Weather Bureau, and prospects for a year of abundant water were hailed with jubilation throughout the state.

AN INTERESTING side-light on the rainfall situation is the fact that a "weather prophet" who has attained a large measure of publicity from his accurate—or fortunate—predictions in the past, released a prognostication at the

close of March in which he announced, in phrases as unqualified as are ever employed in such forecasts, that April would be a rainless month in California. The fact that the first week in April brought more precipitation than has ever before been recorded for the entire month provides food for thought for those who are inclined to give undue credence to such prophecies.

Speaking of the claims to accuracy in weather predictions of exponents of "sun-spot theories" and similar systems of forecastings, in a recent conversation with the writer, Dr. Robert Millikan, probably as great a physical scientist as the world now possesses, disposed of their claims in a brief but pithy observation, when he said: "The weather, as we all know, is a relatively local matter. Sun spots are not a local matter. It is difficult to see, therefore, how they can be interpendent."

GOVERNOR C. C. MOORE, of Idaho, who led a trade mission of state officials and business men to Southern California during March, recognizes the problems of water supply, irrigation and hydraulic developments as among the fundamentals of statesmanship. In an interview with a representative of MODERN IRRIGATION, Governor Moore gave an interesting statement with reference to the hydraulic problems which are now facing the west.

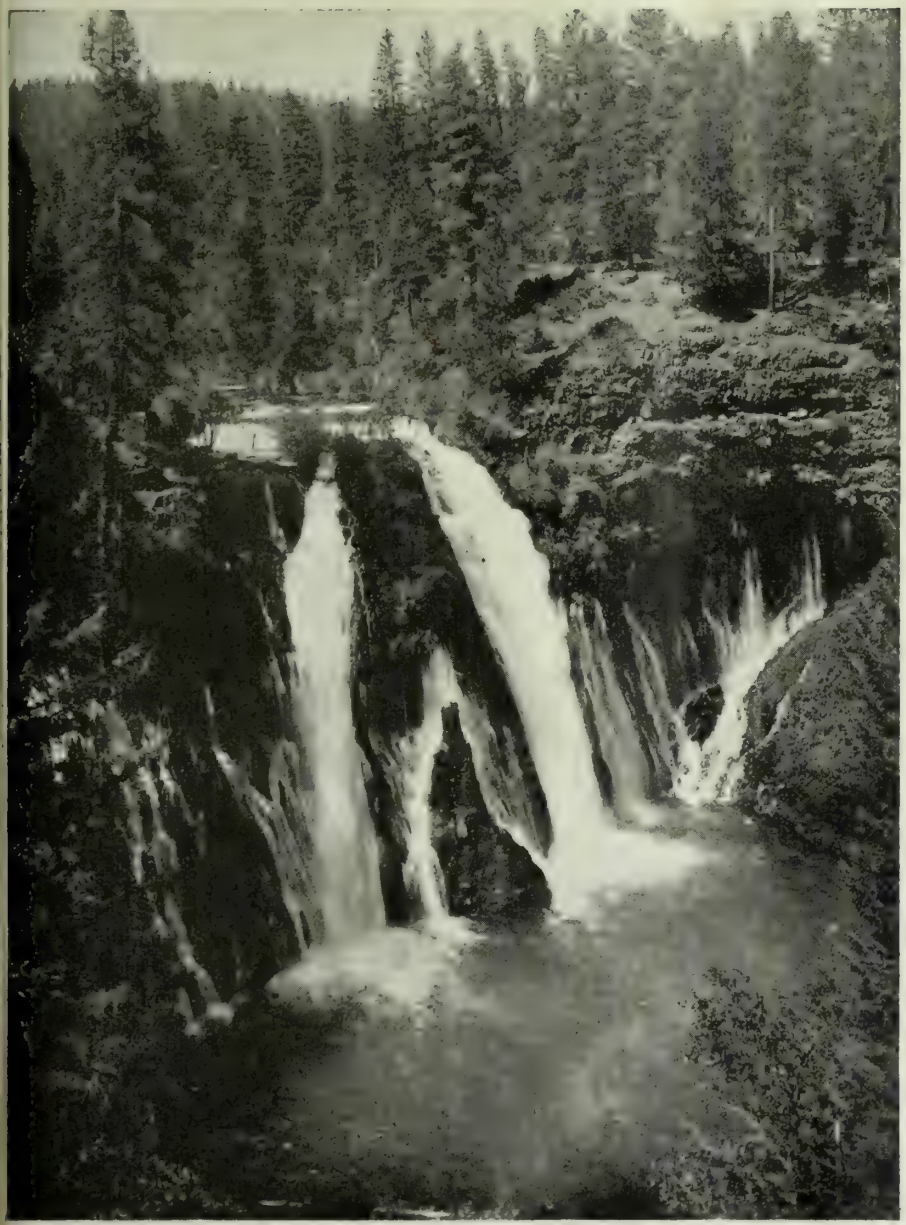
"The question of widest interest," said the Governor, "is the question of the development of the Colorado River. The problem of the Boulder Canyon project involves an enormous contemplated expenditure in the interest of making available a large and much-needed potential resource of the whole nation. While I am opposed to the government engaging in the power business, and believe that this, like other business activities, should be left to the ingenuity of private endeavor, nevertheless, because of the complications of interstate nature that exist in the Colorado River situation, the enormous investment which the proposed plan would require, and the national importance which its development may assume, the Boulder Canyon project may quite properly be a problem for the national government. But I should doubt the wisdom of its development under any plan which would put the government permanently in the commercial power business. I believe the states affected should have the right to develop this resource in their own interests, as and when they desire.

"Idaho has a quite similar problem in dealing with her sister states in the allocation of the waters of the Columbia River. This is being urged by the state of Washington in the interest of the early development of the Columbia Basin project. Idaho is addressing itself diligently to the task of gathering data on this stream with a view to outlining a position which will, first, adequately protect her own interests, and second, serve the needs of her neighboring states. This study is being conducted under the direction of Idaho's state department of reclamation. Until the data are gathered and compiled, no definite statement can be made of the position of our state."

"IDAHO, herself, is making a notable record in the matter of utilizing her water resources," added the Governor. "During the last 26 years some very ambitious projects have been constructed, until now the state contains an irrigated area of more than 3,000,000 acres.

"Favorable natural conditions, careful planning, engineering skill, and permanent materials have been employed in the building of these projects. The water supply is abundant and its delivery to meet all crop needs is always assured. The natural flow of streams providing water for this area is regulated in more than one hundred storage reservoirs of comparatively large size, having an aggregate storage capacity of 5,400,000 acre-feet. This capacity does not include the American Falls Reservoir of 1,700,000 acre-feet now under construction. Farmers are not always required to apply water concurrently with its appearance in natural flow. Stored water is available when the crops require moisture. Full production is, therefore, always assured.

"About two million acres of the State's irrigated area is embraced in municipal irrigation districts. In pioneering this development, the State, like most of the arid West, made errors in its original financial setup and, unfortunately, some investors did not secure the returns to which they were entitled and rightfully expected. The present policy of the State is to carefully guard its credit by preventing the offering of unsound securities, thus lending stability and positive value to its irrigation district bonds. This policy has so far restored confidence that in recent sales of such securities money has been obtained on a 5¾ interest basis in addition to a substantial bond premium."



Beautiful, as well as valuable—this photograph shows Burney Falls, on Burney Creek, Shasta County, California; one of the streams covering which adjudication proceedings have been conducted by the California Division of Water Rights.

WHOSE WATER ?

How California Deals With the Troublesome Water Rights Question

By GORDON ZANDER

Associate Hydraulic Engineer, California Division of Water Rights, Department of Public Works.

GROWTH and progress in any western state in the future will be largely dependent upon an orderly, systematic and judicious development of its water resources, and in order that such development may proceed, and that the necessary capital may be attracted, titles to the use of water must be established and made secure. In California, the recognition of this fact is manifest in the attention given to the adjudication of water rights.

Since December 19, 1914, the date on which California's Water Commission Act went into effect, water rights by appropriation in that state can be initiated only by application to the Division of Water Rights (or to the State Water Commission, its predecessor), in which cases state supervision is exercised over the acquisition of the rights.

If permits are issued, followed by construction and application of the water to beneficial use with due diligence, the rights become established and of record as to priority and amount of water appropriated.

Prior to the enactment of the Water Commission Act, however, no definite or specific control was exercised over the acquisition of water rights by appropriation, nor was it even compulsory that they be recorded. No limit was placed upon the amount of water that could be claimed, and it was the custom to file upon much more water than it was expected to utilize. In many cases the filings were not followed by construction and use, and consequently no rights became vested; on the other hand there are many valid appropriative rights in existence which are based upon use alone, and of which there is no record.

As a result of the conditions prevailing prior to the enactment of the Water Commission Act, all appropriative rights initiated prior to December 19, 1914, are undetermined as to amount of water appropriated and many are undetermined as to priority except on the comparatively few stream systems in the state where the water rights have been adjudicated. In addition to the undetermined appropriative rights, there are the many water rights claimed by virtue of riparian ownership, prescription or adverse use, of which there is no record.

In order that all existing water rights may be determined and placed of record, to the end that they may be made the basis for distribution of water, under the supervision of water masters whenever it becomes necessary that such control be exercised, and that they be known so that they will not be infringed upon by new rights which may be acquired, the Water Commission Act has, in Section 24 and in Sections 25 to 36f, inclusive, provided for the adjudication of water rights.

SECTION 24 of this Act provides that any suit involving the determination of water rights which is pending in the Superior Court may, in the discretion of the court, be transferred to the Division of Water Rights as referee.

Under this procedure all water rights of whatsoever character may be included, and the proceedings may be initiated by the filing of a friendly suit by one or more claimants against all other claimants from the stream system, following which the transfer of the case to the Division of Water Rights will doubtless be granted if petitioned for by the parties.

Upon receipt of an order of reference, the Division proceeds to ascertain the physical facts through an investigation in the field, which ordinarily includes measurements of the water supply and of the various diversions, surveys of the various irrigated areas, and a study of the various factors upon which the duty of water is based. If it is impossible to get all of the claimants to agree upon an allocation of the water supply after the physical facts are known, a hearing is held by the Division, at which the necessary testimony is heard upon which to base findings as to priorities and any legal points that may be involved. A court reference is terminated by a report from the Division to the court, which includes findings of fact, conclusions of law, and a proposed judgment and decree.

The report is, of course, subject to modification or rejection by the superior court, and after a hearing upon any objections thereto has been held by the court, a decree is entered establishing the water rights involved. The court reference procedure is the only method by which riparian and prescriptive rights may be brought before the Division of Water Rights for determination; consequently it is the procedure that should be followed on all stream systems where such rights are involved to any considerable extent.

Section 25 of the Act provides for the initiation, either by the Division of Water Rights on its own motion or by a petition signed by one or more claimants from the source involved, of proceedings for the determination of all water rights by appropriation upon any stream system. In the case of proceedings thus initiated, the procedure outlined in Sections 25 to 36f of the Act must be followed, and only water rights by appropriation may be included. The procedure is similar to that followed under court reference, except that upon completion of the field investigation each claimant is required to submit proof of his claim in the form of an affidavit; any claimant is allowed to contest the proof of any claim, and hearings are held on all contested claims. The proceedings are terminated by the filing of findings by the Division in the superior court, which findings may be confirmed or modified by the court after a hearing on any objections raised.

BY THE procedure provided in the act, adjudication proceedings may be initiated in advance of actual conflict between water users, and injury to vested rights due to diversions by junior upstream users may be averted. Trouble may thus be anticipated and forestalled, the continuance of amicable and neighborly relationships promoted, and strife and litigation reduced to a minimum. All water rights on a stream system may be determined in a single proceeding, which rights might otherwise form the basis for numerous individual suits. The physical facts are determined by specially trained engineers, who are state employees and disinterested parties, and as a result the conflicting evidence as to physical facts with which a court is usually confronted in water right cases is largely eliminated.

The length of time consumed by adjudication proceedings will vary from one to three years, depending upon the extent of the water rights involved, and the number and nature of the contests that may develop. A time record was recently made in two proceedings in Modoc County, one involving the water rights on Owl Creek and the other involving those on Soldier Creek. These two cases were transferred to the Division by court orders dated April 28th, 1925, and May 21st, 1925, respectively; the field investigations were conducted simultaneously covering the major portion of the 1925 irrigation season; the maps and engineering reports were completed in December, 1925; and the reports of the Division, as referee, were forwarded to the court on March 8th, 1926. It is expected that decrees will be entered in the two cases in time to be enforced during the 1926 irrigation season.

The cost of adjudication proceedings depends upon the total area irrigated from the stream, the sizes of the various tracts of land irrigated, the topography of the area which must be surveyed, the number of diversions, the accessibility of diversions, the quantity of existing hydrographic data, the number and nature of the contests that may develop, and the distance of the stream from Sacramento. On the adjudication proceedings already completed by the Division, the cost per acre of irrigated land has varied from thirty-five cents to sixty-seven cents. Present indications are, however, that cost of several pending proceedings which involve relatively small irrigated areas will run as high as a dollar per acre.

Automatic water stage recorder established on Soldier Creek, Modoc County, California, by means of which a continuous record of its flow was obtained throughout the 1925 irrigation season.

TO DATE the Division of Water Rights and its predecessor, the State Water Commission, have undertaken fifteen adjudication proceedings, of which ten have been initiated by court reference and five under the provisions of Section 25 of the Act. Of the proceedings undertaken, seven have been successfully terminated by court decrees, one failed of completion because of involved land ownerships and other pending litigation, and seven are still pending.

The completed adjudications have resulted in the establishment of all water rights on the following stream systems:

Willow Creek in Lassen County, from which about 1000 acres are irrigated.

San Pedro Creek in San Mateo County, from which about 500 acres are irrigated.

North Fork of Cottonwood Creek

Irrigation Districts Association Holds Annual Meeting

Adopts Important Resolutions, Hears Valuable Discussions and Addresses, Views Exchequer Dam

By HUGH CRANE

MEETING at Merced, California, during March, the Irrigation Districts Association of California, representing the greater part of the district organizations of the state, went on record by resolution with reference to several questions of vital importance to irrigation. The Association—

Endorsed the proposed Boulder Dam development on the Colorado River.

Opposed the unnecessary destruction of brush and forest cover on the upper watersheds of western streams, and urged the government to inaugurate a stricter policy of conservation.

Condemned proposed state legislation providing for a tax on the gross revenue of publicly owned utilities.

Urged that a nationwide campaign be instituted by the Bureau of Reclamation, to present the "sunny side" of the accomplishments of reclamation during the past 23 years.

Declined to endorse the policy of statewide water development advocated by the California Farm Bureau Federation, preferring to withhold action until the current survey of the state's resources has been completed.

THE MARCH meeting was made doubly valuable to the Association by the circumstances under which it was held. The members met as the guests of the Merced Irrigation District, and after business sessions at which practical addresses and discussions were featured, more than one hundred of them enjoyed a tour of inspection of the Exchequer Dam, now nearing completion.

William Durbrow, president of the Association, was in the chair when the meeting convened, and after a brief historical summary of the work of the organization, introduced C. E. Kocher, president of the Merced Irrigation District, who welcomed the guests.

Matters of irrigation law, litigation and legislation held the center of interest during the opening session. A. E. Chandler, under whose direction briefs were filed on behalf of the Association in the Herminghaus Case, reported on the status of this important matter. Briefs were filed for the Association by its attorneys as *amici curiae,* opposing the contentions of both litigants. A letter of thanks was received from the Nevada Irrigation District, for the assistance rendered by the Association in its recent case before the Federal Power Commission. W. D. Wagner, secretary of the Association, reported on the California legislative situation, pointing out that although the organization expected to have only six measures before the last session of the California legislature, some sixty bills made their appearance, but few of the bills which lacked the support of the Association became laws.

Paul Bailey, deputy chief of the California Division of Engineering, reported on the progress of the investigations, undertaken by his Division, of the water resources of the state; and Edward Hyatt, Jr., Chief of the Division of Water Rights, spoke on some of the problems of the Division.

Other speakers at the first day's session were R. V. Meikle, chief engineer of the Merced Irrigation District, who discussed some aspects of the Exchequer Dam construction; W. S. Rosecrans, vice-president of the state Farm Bureau Federation, who presented the policy of his organization with reference to state water developments; C. L. Childers, attorney for the Imperial Irrigation District, who spoke on the Colorado River problem and Boulder Canyon project; George L. Swendsen, chief engineer and general manager of the Fresno Irrigation District, who discussed "Irrigation District Management," and John Dwight Neale, of the J. R. Mason & Company, who spoke on "Irrigation District Bonds."

AMONG the topics arising for discussion were several of general interest. A letter from the Stinson Irrigation District came before the Association in which the question of a district's responsibility for the delivery of water upon the land of the user was raised. Officials of the Stinson district declared that they had heard that, in a recent decision against the Turlock district, it was held that it is incumbent on a district so to construct its system of ditches that the district can deliver water to the land of the user.

Discussion revealed, however, that in the case of Bushman vs. Turlock District, the decision was the reverse of the understanding of the Stinson district.

Comparative merits of district-owned and maintained laterals as against privately maintained ditches were urged pro and con in a long discussion centering on the question of lateral ditches and their management.

WILLIAM DURBROW
President, Irrigation Districts Association of California

The incomes of irrigation district officials and employees are exempt from income tax, so far as they are derived from the district, it was announced by the secretary, in response to inquiries from several districts. Incomes from the political subdivisions of states are exempt from the operation of the federal income tax, and irrigation districts are specifically included in this class of exempt organizations by the Revenue Act of 1926, as are Drainage and Reclamation districts as well.

RESOLUTIONS adopted by the Association included the following endorsement of the Boulder Dam and All-American Canal, introduced by Mr. Childers, of the Imperial Irrigation District:

Resolved, that the Irrigation Districts Association of California, assembled at Merced on the 11th day of March 1926, and representing approximately four million acres of irrigable land in California, regards the early construction of the Boulder Dam and All-American Canal as a unit of primary importance to the irrigation interests of California in general, and to the safety of Imperial Valley in particular, and urges upon the representatives in Congress from California to use every effort to pass the Swing-Johnson Bill, thereby authorizing this development at the present session of Congress.

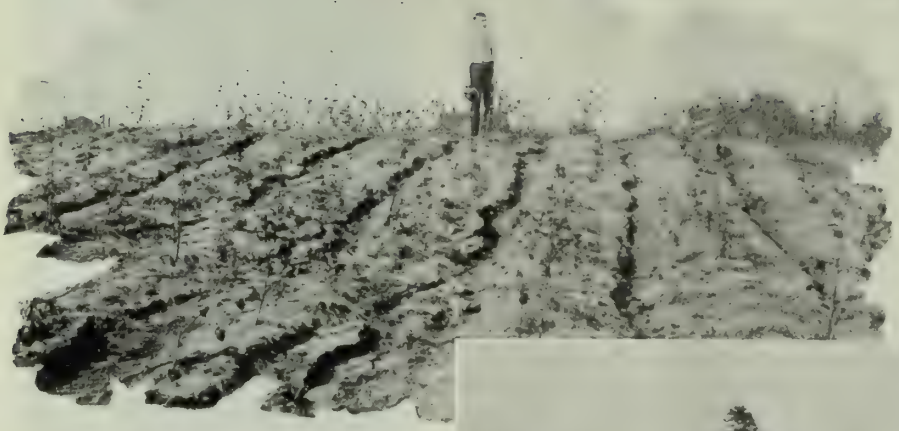
And be it further resolved, that a copy of this resolution be handed to each member of Congress from California and a copy spread upon the minutes of this meeting.

Mr. Childers also brought up the pending case of Crawford vs. Imperial

(*Continued on Page 29*)

How Drainage Pays the Farmer

There is No Investment That Returns Better Dividends to the Farmer Than Good Drainage



Land that is well drained, compared with land that wasn't. ABOVE: *the type of erosion that occurs in many fields, unterraced, where clean cultivated crops are grown.* BELOW: *Land prepared with the typical broad-base graded terrace.*

By S. H. McCRORY*

Chief of the Division of Agricultural Engineering, Bureau of Public Roads, U. S. Department of Agriculture

THAT A well drained soil is the foundation of successful agriculture is an accepted fact. Many of our fields are naturally well drained but there are also large areas that need artificial drainage if they are regularly to produce the best yields of which they are capable. There is scarcely a farm in the country on which there is not some land which would be benefited by better drainage. In places the individual farmer can by his own efforts provide good drainage for his lands. In other places a few farmers must organize under the state drainage laws if their farms are to be drained while in other localities it may be necessary for very large groups of land owners and other interests to combine if adequate drainage or flood protection is to be secured. In the last 35 years great progress has been made in the drainage of our wet lands. Millions of acres have been supplied with outlet drains and made available to the farmer. Truly a great work has been accomplished.

Much has been accomplished but more remains to be done. Outlet drains have been supplied through large areas. Farm drainage unfortunately has not kept pace with the construction of outlet drains. The best information available indicates that there are in the United States today about 200,000,000 acres of lands that would be benefited by better drainage. In recent years the American farmer has had a difficult situation to contend with and in many instances it has cost him more to grow crops than they could be sold for.

I believe that many farmers by improving the drainage of their farms could materially increase their income. Let us consider for a moment what drainage does for the soil and plants that grow from it. A supply of air, water and plant food are necessary for proper plant growth. Drainage removes excess water from the soil, air enters the pores from which the water has been removed and plant roots can penetrate into the soil.

The roots of most plants will not penetrate below the levels of the free water in the soil. If, in the spring, the water table is only a few inches below the surface the roots will penetrate only that deep. When a dry spell comes the roots soon exhaust the moisture in the soil and plant growth is stunted or entirely stopped. Had the soil been well drained the roots would have penetrated deeply in the soil and when the dry spell came would have had a much larger amount of soil from which to draw water and plant food. With some crops it is important that the water table be held at the uniform level. If it fluctuates slowly it kills the plant roots as it rises and when it falls the roots are diseased and do not follow the moisture downward so readily as they first did. Some investigations that we have made recently in Florida indicate that this problem is of considerable importance in the citrus groves; studies in the West indicate that the same condition holds true for the orchards and for alfalfa.

The ideal form of farm drainage is undoubtedly tile but with the present price of tile and labor many farmers feel that they cannot afford to undertake such expensive improvements. Recently, I have been giving considerable study to farm drainage problems and I

*Delivered before the Fourteenth Annual Meeting of the National Drainage Congress, Oklahoma City, Okla.

wish to submit to you for your consideration some ideas on this subject.

ON MANY farms throughout the United States considerable benefit could be obtained if the farmer would construct surface ditches that would remove or prevent water from ponding on low places on his farm. These drains he could construct during the intervals between farm operations when he has a few spare days. The ditches could be built either with a shovel, with a plow and road scraper, or with a ditcher.

If the farmer plans to undertake such improvements he should observe closely conditions on his wet lands during heavy rain storms and notice how the water flows and where it stands and where the lowest places are in the ridges which hold the water on the land. It would be well to mark these places with stakes so that he can locate them later. He should then, at the first time that crops on the land will permit, build his ditches, endeavoring to keep a uniform grade so that the water will flow out readily.

When the first rain storm occurs after he has built the ditches he should observe how the water flows through them and if there are any high places they should be marked and after the water has had a chance to run off and the soil dry out these places should be removed. Many a farmer would profit greatly if he were to spend some of his time for the next year in building such ditches. Improvements of this character call for no expenditure of money and only the use of his own time and equipment.

When the farmer feels that he can afford to make some expenditure to improve his farm, tile drainage is one improvement that should have careful consideration. Personally, I believe that there is no better investment than a well planned and carefully laid tile drain. If, as is the case with most of our farmers now, there is a limit to the amount that he can spend, I would locate the drains so as to drain that portion of the field which had the greatest need for drainage. By carefully fitting the drains to the field much can be accomplished with a few strings of tile. If later more drains are found advisable they can be added. In many fields, however, a few random lines of tile are all that are necessary.

HAND IN HAND with drainage should go the prevention of erosion. If the fertility of our fields is to be maintained this is essential. It is more than this, in many localities as streams are filling up and losing their value as drainage channels. This is true in Oklahoma, in Iowa, in North Carolina.

Recently, we have been conducting some experiments in co-operation with the North Carolina Agricultural College and the North Carolina Department of Agriculture to ascertain if we could determine some of the fundamental principles which control the designing of terraces for preventing erosion or washing of the soil from cultivated fields. During the course of these experiments we have been catching and weighing the soil washed from a series of plots.

During one six weeks' period in the summer of 1924 rather heavy rains occurred and the soil was washed from two of the plots at the rate of a pound per square foot or more than 21 tons per acre. Stated another way, a sheet of the soil about one hundredth of an inch thick was washed away.

Land on which this occurred was not a steep slope, but is gently rolling. Many good farmers would say that such a soil on such a slope would not need terraces to prevent erosion. The University of Missouri in a series of similar experiments which they have reported recently secured quite similar results. There is perhaps no more important problem confronting our country today than the conservation of its arable lands. The best method that we now have is the broad-base variable grade terrace. With very little assistance any farmer can construct it with his own teams and equipment and no expenditure of funds. Properly constructed it should practically stop the washing of his fields and permit him to obtain full benefit from the fertilizers that he applies. Terraces will also stop the sand and silt that has in the past been washed down into our main drainage channels and prevent their becoming obstructed.

The trenching machine at work. These machines are taking much of the drudgery out of large-scale drainage operations where they are employed

Mr. McCrory Says:

In too many places we have stopped with the construction of outlet drains and have not encouraged the farmer to complete the farm drainage on which his prosperity depends.

It has been said that the last ten per cent spent on the completion of a drainage system brings ninety per cent of the profits. When this ten per cent is spent in improving the drainage conditions of the farm so that full use can be made of the outlet drains, this is frequently the truth.

The drainage that pays is the drainage that permits the farmer to increase his yields and to secure the maximum return from his lands.

There are in the United States today about 200,000,000 acres that would be benefited by better drainage.

ONE DIFFICULTY or defect in our drainage work in the past has been that in many places we have stopped with the construction of the outlet drains, and have not encouraged the farmer to complete the farm drainage on which his prosperity depends.

It has been said that the last 10 per cent spent on the completion of a drainage system brings 90 per cent of the benefit. When this 10 per cent is spent in improving the drainage conditions of the farm so that full use can be made of the outlet drains that have been provided this is frequently the truth.

The drainage that pays is the drainage that permits the farmer to increase his yields and to secure the maximum returns from his lands.

During these periods of depression when the farmer does not feel that he can afford to make heavy outlays of capital for improvements, I believe that we should bring to his attention

(*Continued on Page 49*)

Pipe Corrosion—Its *Causes*, and a *Preventive Method*

Waterproof Coverings are Saving Money for Many Western Irrigation Districts

By DOZIER FINLEY

IT HAS long been the custom to design certain steel constructions with such an excess of metal that the structure will be serviceable even after a considerable portion has been destroyed by rust. This appears to be especially true of steel pipe of nearly all weights and sizes. Everywhere we may find pipe sufficiently thick to withstand a pressure of 500 pounds per square inch and yet the working pressure may not be above thirty pounds. It is seldom that pipe fails by water hammer or by the stresses set up by expansion and contraction until after it has been greatly reduced by corrosion. Furthermore pipe usually develops leaks long before it fails through excessive mechanical stresses. This is due to the ugly habit of "pitting," by which "pits" may be formed extending entirely through the pipe wall although other portions of the pipe may be as perfect as on the day it was manufactured.

It is estimated that corrosion destroys steel pipe in the United States to the value of over $20,000,000 per year. Probably over $30,000,000 is spent each year for excess metal in pipe walls so that a longer time will be required for pitting to render the pipe valueless.

This 44-inch water line, near Niles, California, was protected with a mechanically applied felt base bituminous covering.

STEEL IS CHEAP and may be had in almost unlimited quantities. If it rusts away the user builds succeeding structures heavier in weight, seeking to protect the easily corroded metal with extra thicknesses of the same metal. It is a policy not dissimilar to that of the housewife who exclaimed, "Oh, the moths destroy garments so quickly—we shall have to buy much heavier clothes!"

Fortunately the irrigation engineer cannot be charged with a wasteful use of metal in his pipe construction. The generally low pressures employed, the competition with open ditch construction, flumes and concrete pipe, and the limited amount of money usually available have brought about the practice of using pipe only sufficiently heavy to withstand all mechanical stresses save that due to diminished internal pressure.

But corrosion of underground steel irrigation pipe will proceed as rapidly as corrosion on heavier pipe used in other services, except that irrigation pipe is seldom subjected to actual electrolysis. Having thinner walls, irrigation pipe may be expected to become unserviceable in far shorter time than standard lap welded steel pipe. But the irrigation engineer meets this situation by seeking to use the most effective methods of protection against corrosion.

It has been a custom for years to dip pipe of this character in molten asphalt. The coating thus produced ranges from about ten to seventy thousandths of an inch thick, according to the duration of the dip, the temperature and other factors. On the inside of the pipe such a protective coating is no doubt effective, but on the exterior its value is questionable, because handling before the pipe is laid and covered will bring about so much abrasion that corrosion and pitting find ample opportunity to begin their activities even before the pipe is put in service. Tests have shown the most careful inspection will not detect the presence of a large percentage of such abrasion.

DOZIER FINLEY

Mr. Finley is director of technical research for the Paraffine Companies, Inc. His article discusses some of the problems of protection for underground pipe in irrigation and water works use.

PAINTING of underground pipe is apparently of little value unless soil conditions are very favorable—and in our Western states soil conditions are usually unfavorable. Dipping in tar pitch is not practiced in the west because tar pitch is produced only in extremely small quantities on the Pacific Coast. Galvanizing is generally regarded as a protection against corrosion, but in bad soils the galvanized coating itself becomes subject to attack. Encasing the pipe in concrete usually does not take account of expansion and contraction, which can only be equalized between the concrete and the steel by using an excessive quantity of concrete.

Probably the greater part of the discussion on corrosion of irrigation pipe should be addressed to the western states for two reasons; (1) corrosion of pipe is uniformily more severe in the west than in the east and (2) irrigation is practiced almost solely in the west. It is difficult to say just why this corrosion is more severe in the west. It can hardly be attributed to the soil, because similar soils occur in both the east and west. It cannot be attributed to the alternate wet and dry seasons of the west because pipe in certain limited sections of the Mississippi valley, where summer rains keep the ground continually wetted, will be destroyed as quickly as pipe in the worst sections of the west.

The Bureau of Standards at Washington is conducting tests on pipe buried

in different soils in over forty locations in the United States. When these tests are completed several years hence, we may know more nearly why one soil is corrosive toward pipe and another is not. At present we cannot accurately predict the corrosive action of a soil—we can only judge of its action by examining steel specimens which have been buried in it.

IT APPEARS strange we do not know exactly why steel corrodes. Many factors and agents appear to combine to produce the rusting action, but we do not know just what takes place as particle after particle is torn away from the parent metal and converted into the material known as "rust." When the action has been followed as far as scientific observation will take us, there remains a gap—that gap we try to bridge with theories.

All the collected facts and all the theories pieced together, agree on one thing (which indeed is a matter of common everyday observation): iron or steel will not rust if kept perfectly dry. We are led to believe, then, that either water itself is the agent engaged in the corrosion or that the water, through its solvent action, carries to the metal dissolved foreign matters which bring about the attack. It has been demonstrated that pure water, free from air and other dissolved gases, exerts only the most minute rusting action on iron. But this action is increased many fold if air, or certain salts, even though neutral (i. e. neither acid nor alkaline) are dissolved in the water. Water, therefore, appears to be at least one of the factors or agents which has the widest influence on whether or not corrosion shall take place.

There are, it is true, other factors. The writer has found the texture of soil may cause corrosion to appear at certain portions of a pipe line, while other portions are unaffected. Where the soil is wet or dense or the pipe buried deeply, while adjacent portions of the pipe are in loose or dry soil, or are near the surface, there is very frequently corrosion, and the corrosion appears on those sections, strange as it may seem, which have been cut off from the air by extreme density or wetness of the soil or by deep burial. Yet it is not the access of air that prevents corrosion—it is merely that on some sections air reaches the pipe more freely than on nearby sections—in other words it is the difference in the conditions which brings about the corrosion. By electrical measurements this difference of soil conditions around adjacent pipe sections has been demonstrated to set up electrical currents in the pipe; in other words to make an electrical battery out of pipe and soil. Where there is a battery of this type some of the metal must be destroyed—in this case the only metal is the steel of the pipe and consequently a portion of that is destroyed. This condition cannot be combatted by burying the pipe at a constant depth in soil of uniform texture and wetness because these factors themselves cannot be controlled. But there are other factors which cause corrosion—a piece of pipe so small that it is all buried in soil of uniform texture and wetness, a piece of one inch pipe one inch long, we will say, often will corrode just as actively as a ten inch pipe line a mile long!

BUT, as we have said, water appears to be at the root of this evil in some way. If the metal of the pipe can be kept dry the corrosion should not take place. Dipping of the pipe apparently affords a very good interior protection and dipped pipe can be laid without serious injury to the interior dipped coating. The interior of the pipe is exposed only to the flow of water and therefore the metal, if any happens to be unprotected, is subjected to a condition of extreme uniformity; this usually is favorable to a low rate of corrosion.

Recognizing the fact that the average dipped coating is not wholly dependable as an exterior protection, efforts were made as early as 1905 to wrap bituminous saturated and coated felts around pipe by hand. At first the wrappings were not tightly applied and water found its way between the pipe and the covering. In about 1916 mechanical application of the covering was tried. By means of heavy machines, which drew up the highly waterproof covering tightly against the pipe and cemented it thereto by a heavy asphaltic cement, 250 miles of pipe were covered for the Lindsay-Strathmore and Terra Bella Irrigation Districts. This pipe was all of 16 gauge, some of it being as large as 36 inches in diameter, and was asphalt dipped before being wrapped. When examined by the writer in 1925 this pipe was in practically perfect condition—in fact there was no record of any leakage which had come from corrosion starting on the exterior of the pipe.

Since 1916, thousands of miles of irrigation, gas, water and oil lines, ranging from ¾-inch to over 60 inches in diameter have been covered by mechanical application of bituminous covering materials made by the company with which the writer is associated. Applying these coverings has been done either in the shops where the pipe was fabricated, as in the case of irrigation and waterworks pipe, or by means of the Pabco Portable Wrapping Machines used in the field or pipe storage yards in the case of oil and gas pipe. Mechanical application of waterproof covering to pipe for underground service is rapidly becoming standard practice—it is so much less costly and more effective than "protecting steel with steel" that it is now the policy with some companies to cover all pipe, regardless of slight differences in soil conditions; corrosion is so uncertain in the location and intensity of its attacks that it doesn't pay to "take a chance." It has since been proved that had the Lindsay-Strathmore and Terra Bella Irrigation Districts "taken a chance" and installed unprotected steel pipe of similar weight in place of the covered pipe, replacement and maintenance down to the present date would have reached a figure probably exceeding the original cost of the system.

Wrapping 10-inch pipe in the field with two layers of felt base protective bituminous covering, and an outer layer of non-adhesive paper, using portable pipe wrapping machine. Mr. Finley tells how these machines save money.

Two Rivers of Doubt

Shall Conflicts of Interest on the Colorado and the Rio Grande be Settled Jointly or Individually?

By C. H. PEASE

Secretary, Lower Rio Grande Water Users Association

PART TWO

OVER two of the Southwest's great rivers, destined to loom large in the future development of irrigation, there hangs a shadow of uncertainty. One—the Rio Grande—for a large part of its course forms the international boundary line between Mexico and Texas, and empties into the Gulf of Mexico. The other—the Colorado River—originates high in the Rockies, flows through most of the lower western states, and after a short, but important, journey through Mexican territory, enters the Gulf of California.

The destinies of both streams are shadowed by a cloud of doubt. There are analogies between them, and there are interesting contrasts. But—most significant—there is a definite relationship of the one to the other, which makes the settlement of the problems of the Colorado a matter of vital interest to the water users who derive their supply from the Rio Grande.

In the first installment of this article, the situation along the Rio Grande was briefly sketched, with a view to showing that some kind of an international agreement, looking toward the creation of storage reservoirs on that river, is urgently demanded by the present status of American lands and the impending development of lands on the Mexican side.

For obvious reasons, Mexico has not as yet evidenced any concern over the constantly increasing appropriations of water that have been made on the American side. She has but a relatively insignificant development in the Delta region. There are a few small plantations located on the immediate bank of the river which produce principally cotton. Small pumping plants supply water for the irrigation of these lands, which comprise but a few thousand acres, all told. So far, there has been little difficulty experienced in getting sufficient water for all demands on both sides of the river. There have been no controversies over this water supply and no protests from Mexico.

That Mexico has not exploited her own lands is doubtless due to the unsettled political and industrial conditions that have prevailed in that country during the period in which the American side has made its rapid advance. In fact, during the early period of American development, a rather ambitious undertaking was launched on the Mexican side that rivaled in size the very largest of the projects on the north side. Several miles of main canal were completed and pumping machinery had been assembled, when the appearance of the army of Pancho Villa, the bandit, brought an abrupt termination to the enterprise. It has never been resumed.

In the meantime, appropriations on the American side have reached the point where the entire normal flow is required to meet the demands of the lands already brought under the several projects. If these diversions were so situated that Mexico could be deprived of access to the water she would doubtless have viewed with more concern these gradual encroachments. However, it is physically impossible to deprive Mexico of the ability to help herself to this water. By the simple expedient of locating her own pumping plants on the south bank, Mexico will have an equal chance to supply her needs.

In fact, Mexican engineers are in possession of complete data covering a proposed canal diverting from the San Juan River, the lowest of Mexican tributaries, at a point where backwater from the Rio Grande is always present, even at low stage. Such a canal, without touching the Rio Grande, would draw away the greater portion of its low water flow some twenty miles above all American diversion points. This proposed Mexican canal will command practically all of the irrigable land on the south side, several hundred thousand acres in extent, and comprising some of the finest lands in the Republic. On another large tributary, the Concho, there is a considerable area of irrigable land. It has been reported that Mexico has granted concessions for the irrigation of about 150,000 acres in the Concho valley. The Concho is at present an important source of low water flow in the lower Rio Grande.

MEXICO has no occasion for concern over her rights in the Rio Grande. So long as no extensive irrigation is attempted on the opposite side of the river, the only immediate problem facing the American irrigators is to develop additional water resources to keep pace with the expanding cultivated area. But it does not take a very long look ahead to recognize the possibility of complications that may greatly disturb the present status of things. So long as the shadow of Mexican appropriations hangs over the head of the Delta farmers, there must be a feeling of insecurity and a cloud on the title to the fundamental necessity of all industry there.

Fortunately, there are available storage sites which offer the opportunity to increase the irrigated area at least four times that which can be supplied from the normal flow alone. However, these

What Irrigation Has Done For My State—*UTAH*

By O. W. ISRAELSEN

DR. ISRAELSEN is Professor of Irrigation and Drainage at the Utah Agricultural College, Logan, Utah. His is the third of a series of articles to be presented in MODERN IRRIGATION, *in which eminent westerners will tell what irrigation has meant to their respective states.*

IRRIGATION has made Utah possible. Of course, the 52.6 million acres of the earth's surface known to geographers as Utah are obviously not dependent for their existence on irrigation. But Utah's 26,000 farms, its 200-million-dollar investment in farm land and buildings, its 23,000 farm owners, its numerous sugar factories, condensed milk factories, canning factories, vast alfalfa fields and alfalfa seed producing areas, its prosperous and contented rural population—all these component parts of Utah were made possible by irrigation.

Likewise, the most economical development of Utah's rich mining resources and its extensive coal deposits, the utilization of its grazing lands and its dry-farming possibilities; and finally, the enjoyment of the scenic beauty of Utah's mountains and canyons is greatly facilitated by irrigation, if not actually dependent on it.

IRRIGATION was early recognized as an effective agency in the development of a valuable spirit of co-operation among the Utah pioneers. The first canals were dug by the community, owned by the community and operated by the community. One of the chief functions of the town and city corporations in early Utah days was to clean irrigation ditches, maintain irrigation structures and distribute irrigation water. Even yet, in some Utah localities, the city corporation manages irrigation affairs, but most of the canals are now owned and operated by the farmers who use the water on their lands.

The growth of irrigation in Utah has been steady. During the thirty-year period from 1890 to 1920 the irrigated area has expanded from 250,000 to 1,370,000 acres, the latter being only 2.6 per cent of its land area. If the rate of expansion of the past thirty years continues during the next forty-five years, then Utah will be using all of its available water for irrigation. But even then only six acres of each 100 will receive irrigation water. True, the irrigated area is relatively small, but the irrigation of the six acres makes possible a profitable use of the ninety-four acres for other purposes. But the food production on the fraction of the irrigable land now irrigated is also really significant.

Irrigation has enabled Utah to produce twice as much wheat as her people consume. Since wheat is produced both on the dry-farms and the irrigated farms, let us look at some of the crops that depend wholly on irrigation. In 1924 Utah shipped across her borders, after supplying the home markets, 1054 cars of apples, 962 cars of potatoes, 483 cars of onions, 265 cars of tomatoes, 167 cars of cherries and many additional cars of mixed fruits and vegetables. By irrigation Utah produces annually more than one million tons of alfalfa which, in addition to feeding large numbers of beef cattle and sheep, constitutes the major food for 100,000 cows. In addition to supplying the milk and butter needs of the farm families, there is each year manufactured in factories from the milk of these cows more than 7 million pounds of butter, nearly 3 million pounds of cheese and over 33 and one half million pounds of condensed milk.

Irrigation has also enabled Utah to help maintain the "sweet standards" of the nation. From the one million tons of sugar beets annually produced on Utah's irrigated land, enough sugar is made to supply more than five times her population, provided the annual per capita consumption does not greatly exceed one hundred pounds. And finally, there is produced on Utah's irrigated land nearly one-half of all the alfalfa seed grown in the United States.

THUS, irrigation has made it possible to provide, in Utah, happy and prosperous homes for approximately half a million people who are producing large surplus food supplies for the rapidly growing national population. And it is important to remember that the lands which support these homes and produce this surplus food were considered worthless only 100 years ago.

Today, those least informed concerning agriculture under irrigation are asserting that these great accomplishments under irrigation can at best be temporary; that the arid soils are rapidly being exhausted of their fertility, and that a civilization dependent on irrigation for its food supply cannot endure. Contrary

O. W. ISRAELSEN

to this misconception, irrigation has made it possible actually to increase and to make more permanent the fertility of Utah soils. It is true that excessive application of irrigation water on some of the higher lands, and seepage losses from high canals, have caused water-logging of significant areas of low lying land, but these areas are rapidly being reclaimed by drainage. On the other hand, irrigation has facilitated crop rotation and the growth of nitrogen fixing legume crops, and the practice of livestock and dairy farming, all of which have done much toward increasing the fertility of Utah's soils and the establishment of its agriculture on a permanent basis.

And, finally, irrigation has done much for the citizens of Utah. The irrigator, of necessity, has acquired skill in the control of water on his farm. He has learned to receive water from his canal in his turn, and to restrict his use during periods of scarcity. While those who are entitled to the earlier water rights guard their rights cautiously, yet in many instances during times of low stream discharge, they have voluntarily turned their streams on to the burning crops of the less fortunate holders of late priorities.

Likewise Utah's legislators, her attorneys, her engineers, her statesmen, and others of Utah's citizens, have found great advantages in maintaining the spirit of co-operation which irrigation has fostered, and which has made itself vitally felt, in the final analysis of the many perplexing problems and controversies which naturally have developed in the growth of a state that is inherently dependent on irrigation.

Vol. II APRIL, 1926 No. 4

More Sides Than a Few

OFTEN asserted, always accepted, but seldom appreciated is the statement that irrigation is a many-sided subject. In this, as in so many other cases, repetition dulls the edge of truth. There is no dissent from the fact, but there is—perhaps—a lack of imaginative response to all that is implied by the often reiterated statement.

The present difficulties of federal reclamation may be traced, for the most part, to a failure to understand this many-sidedness of irrigation. It was conceived, at the outset of Federal reclamation, that if the engineers would plan and the contractors would build and the government would finance, water and land would be brought together into that ideal union that would have its issue in prosperous, productive, and populous agricultural communities. It has not always been so. Today it is recognized that reclamation is a success only where its many-sidedness was recognized; and where all the factors, either as they have been affected by good luck or good management, received their proper consideration.

The same fault lies at the root of the incomplete success of all agriculture. Farming under any climate, or under any set of conditions, is sufficiently complex. The regrettably low estate of the farmer of yesterday (and today, to a less extent) finds its explanation in a failure to recognize that complexity. A farmer without technical instruction, and often without adequate capacity, was faced with a task which, for its successful consummation, demanded more than a rudimentary knowledge of the economics of supply and demand, the business management of invested capital and employed labor, the physics and chemistry of soils, the biology of plants and of their vegetable and animal parasites, and the financial principles of funding, amortization and marketing. That the farmer, in so many cases, succeeded in solving these problems in a primitive hit-or-miss fashion makes the accomplishments of agriculture the more astounding.

We can see these defects of the past plainly. The defects of the present, originating in the same short-sightedness, are perhaps less evident. They are none the less a fact. The irrigationist readily concurs with the assertion that all of the many factors must have their proper weight in the equation, but too often he proceeds to construct a formula of his own, leaving out some of the most essential ones. Even in current irrigation developments, there is a tendency to hold that a fertile soil, plus an available water supply at an economical cost, plus an adequate complement of competent settlers, are the only prerequisites to feasibility. This is the largest part of the story, it is true; it is an advance over the old theories that water ought to be brought to the land wherever arid land might be supplied with water. But it is not all.

MODERN IRRIGATION is not opposing the extension of irrigation, for it believes fully and sincerely that the "saturation point" is not yet approached, and, in fact, never can be approached. Feasible and successful districts are always in demand and always will be. But projects undertaken without due consideration of the factors of soil fertility, financial feasibility, and a practicable settlement policy, work irreparable damage not only to themselves, but to all other irrigation developments, not to speak of their regretable results from the standpoint of the human element—the disappointments, the hardships, the life failures of those who give their labor and ambition to a project which can not return a fair dividend upon that investment.

But it needs to be recognized, not only in words but in a revision of current conceptions, that construction is not synonymous with irrigation. The engineer, whose tasks bring him so closely into touch with the other factors, and the ultimate success of whose work must depend upon these other elements, ought to be the first to recognize the fact.

MODERN IRRIGATION is the magazine of applied hydraulics; its interest includes construction as one of the important phases of irrigation and water development; but it is not limited to construction. Its

POINT *Of* VIEW

purpose is to spread information on all aspects of the great industry; the conservation of water supplies for tomorrow as well as their use for today; the management of going projects as well as the survey of new ones; the law of hydraulics as well as the technical principles of its application; the economics and finances of the district, the company, and the individual farmer; drainage, politics, management of men and money—all these things that enter into the thoughts and successful work of the industry and its individual members.

Absorbing and Confusing

NOTHING is more absorbing to one interested in the vagaries of irrigation legislation than to follow the congressional career of the Swing-Johnson bill. At the present time the measure is once more before the Senate Committee on Irrigation and Reclamation, where some of its friends and a few of its enemies are busy writing in and rubbing out proposed amendments. The next few days should reveal whether or not action may be expected during the present session of Congress.

Both as a spectacle, and as an important decision in the annals of the southwest's development, the fortunes of the Swing-Johnson measure are worth attention. But one of the most intriguing things about it is the attention accorded it in the newspapers.

The largest number of people to be vitally affected by this measure live in Los Angeles. They are served by newspapers adequate in number if not in content. Most of them gain from the newspapers—or, more usually, from one newspaper—all the information which they get on this subject, or any other matters of public concern. The interesting thing is that they get only the type of information that the directing geniuses of these newspapers are inclined to give them.

Two morning newspapers, the estimable *Times* and the eminent *Examiner*, make a practice of "playing up" Colorado River news. The reader who resorts to them for his information, however, may know in advance what he will find. Day after day, one may refer to the one journal and find that the advocates of the Swing-Johnson bill have swept aside, in one astute and strategic move, all obstacles and opposition, and must now meet only a few minor technical requirements before swinging triumphantly through to victory; and, turning to the other periodical, discover that, at the same time, that ill-fated measure has all but perished of its own weakness, succumbing to the accumulated opposition of its powerful adversaries, and now hangs on, a dead issue, supported by the waning efforts of a few selfish protagonists.

The facts behind the two stories are the same—slender enough it is true—but sufficient to serve as the skeleton around which the journalistic prestidigitators of the modern newspaper can construct a most entertaining body of deception.

This, of course, is an indictment of all journalism of the present day, to a greater or less extent, but it applies particularly to the measure now under discussion. It is too bad. It is worse than too bad; it is tragic, in that it pictures the sincere advocates on "the other side" as selfish, mendacious brigands; it beclouds issues; it obscures the truth.

Let There be Light

A LACK of frankness is one of the things that has made the Colorado River controversy so bitter and so prolonged. There has been too much shouting about principles, on both sides, when only selfish interests were the motives.

For instance, one feature that is typically hedged about with half truths, is the All-American canal. In a letter to a prominent Californian, reproduced in this issue, Elwood Mead, Commissioner of Reclamation, after pointing out some of the international considerations which affect the actions of the federal government with relation to the Colorado River and the Rio Grande, and showing that such actions must be courteous and circumspect on account of the strategic situation of the Latin republic in relation to both rivers, says: "The people of the Imperial Valley, or of Los Angeles, do not seem to realize the precarious situation."

The people of Imperial Valley have a fairly good understanding of the physical features of the problem, because it is always with them. The greater part of the people of Los Angeles do not have even a rudimentary conception of the physical features, let alone the complex considerations of other kinds which it involves.

The All-American canal has been urged by its proponents under the banner of patriotism and principle, as an urgent, vital necessity to the independence of the United States and the maintenance of the peace and dignity of the Imperial Valley. And all the time, many of those who have contended for it on such an extravagant basis, have privately conceded that it ought to be considered merely as a possibility—a demand to be conceded in negotiation—valuable in bargaining but not indispensable as a physical fact.

As with the Swing-Johnson bill, this magazine neither advocates nor opposes the All-American canal. There are strong considerations—valid considerations—on both sides. But it does conceive that it is poor policy for the advocates of the canal to base their plea on any other ground than that which candidly actuates them.

The people do not understand the situation because they are not told the truth. The newspapers will not tell them. They have their own axes to grind. The pros and the contras each shout their own prejudiced story from the housetops, and in the confusion, the man in the street hears little but their accusations of each other.

Keeping Pace With Irrigation

How the Future Development of Irrigation Presents New Problems and New Fields for the Work of the Division of Agricultural Engineering

By W. W. McLAUGHLIN

Associate Chief, Division of Agricultural Engineering, Bureau of Public Roads, U. S. Department of Agriculture

UNDER the heading "An Outline of Irrigation," Mr. McLaughlin told in the March issue of MODERN IRRIGATION *the story of how the present form of organization of the Division of Agricultural Engineering has developed from a simple inquiry into irrigation practice, launched by Congress in the early nineties, and how the functions of that department have been extended as the problems of irrigation and reclamation have become more complex and difficult. In this issue he looks into the future, and discusses the work of his Division with relation to its usefulness in solving the present and future problems of reclamation and irrigated agriculture.*

A KEEN observer of reclamation development, in a recent article, stated that in the immediate future of reclamation there are three general fields involved; that of purely engineering, that of finance, and that of the agricultural engineer. The engineer will deal with those larger problems of engineering. The financial agency will have to devise ways and means of meeting the construction costs and provide a feasible way for the repayment of these costs. The agricultural engineer will have to do with other problems involving the use of the land and water by the farmers.

It will be his field to determine the economic feasibility of the project as outlined and to suggest, should occasion demand, such changes in this plan as may make the project feasible and economical. It will be his lot to balance the cost of land and water, together with incidental development, against the estimated returns and to suggest such changes in terms of repayment of construction charges as can be met by the farmers from the proceeds of the land.

During the past thirty years there have been a great many changes in irrigated agriculture. Pioneer farming is almost a thing of the past and the farming of today is a problem of business. In the early days it was very largely a question of providing sustenance for man and beast. The successful farmer of these times must produce quality as well as quantity and is competing not alone with his next door neighbor but in many instances with his competitor in foreign countries.

The function of the Division of Agricultural Engineering is also changed. During the early years and in fact until rather recently the principle function of this division was to secure and impart the best existing practice in irrigation farming. Such information was disseminated through the press, lectures, personal contact or bulletins. In the more recent years our work has been very largely research for the purpose of determining fundamental principles of irrigation rather than to study existing practices. These research findings are made public by means of bulletins or through the extension departments of state institutions or the federal government.

Our immediate work for the future will be to continue most of the present projects of investigation and research, but with the special reference to the economic features and a better utilization of our water resources. Without going into detail the following list of projects will give you an idea of our present work in reclamation:

Duty of Water.
Loss of Water by Evaporation.
Development of Ground Water for irrigation.
Preparing Land for Irrigation and Methods of Applying Water.
Seepage return due to irrigation.
Irrigation needs and possibilities of the Great Plains.
Effect of Ground Water on Crop Production.
Utilizing Early and Late Water in Irrigation.
Appliances and Equipment for Irrigation.
Control of Silt in Canals and Reservoirs.
Control of Gravel in Streams during High Water.
Cleaning and Maintenance of Canals and Ditches.
Measurement of Water.
Flow of Water in Conduits.
Sale and Settlement of Land and Cost of Farming under Irrigation.
Irrigation Institutions.
Drainage of Irrigated Lands.
Reclamation of Alkali Lands.

Our future work in studies of cost of irrigation farming and development will include further research into permissible costs for irrigation water supplies and costs of and returns from irrigation activities. There will be continued the study of water requirements of the soils and crops with special reference to better utilization of water in irrigation. The studies in utilization of water will include water development and storage, pumping and reorganization of existing irrigation systems. Special attention will also be paid to drainage problems and the reclamation of alkaline lands.

To my way of viewing the im-

Mr. McLaughlin Says:

Farming today is a problem of business; pioneer farming is almost a thing of the past. The successful farmer must produce quality as well as quantity. He is competing not alone with his neighbor, but with foreign countries.

The field of greatest service is in solving the problem of bettering conditions in going enterprises. This does not imply opposition to new enterprises which are economically sound.

In one district. . . . water is raised 325 feet by means of pumps, while at its north end there is flowing a stream of water used in the irrigation of lands lying below the lands served by the pumping plant. The water in this stream is flowing down through 300 feet or more in elevation before being raised that distance by means of pumps. Such cases as this require the assistance of outside aid. Such work offers the opportunity for the future efforts of our Division.

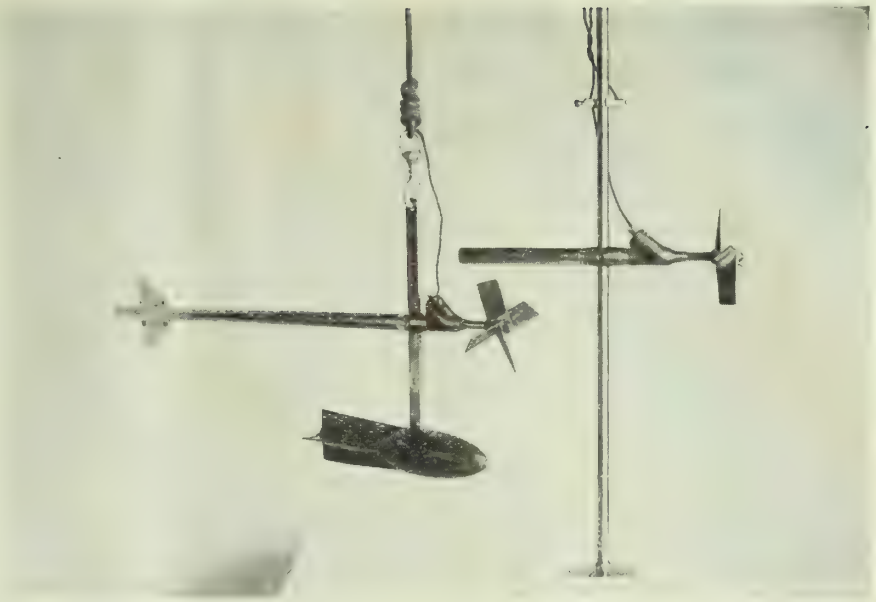
mediate future in reclamation development in the west, the field which offers the greatest possibility for real service with the least chance of failure, is in solving the problem of bettering existing conditions in going enterprises including not only the lands within these going enterprises but additional lands that may be developed in the bettering of conditions affecting lands within the going enterprises.

This betterment may consist in securing by storage or otherwise a supplemental water supply for use in summer and early fall, by reorganizing existing systems, thereby utilizing to better advantage the present water supply, by making possible additional financing or by outlining a different farm program or a change in organization or in methods of operation and maintenance, as well as in numerous other ways.

Do not understand me to oppose the promotion of new irrigation projects that are economically sound; but I believe there is a greener field at present and one more likely to succeed, which is exemplified by such development as is now being undertaken under the American Falls project or that being started under the Salt Lake Basin Project in Utah. Under such projects as the Great Salt Lake Basin the problems of land settlement and colonization and farm financing which have been the stumbling blocks in so many irrigation projects, are much reduced.

Let us illustrate the problem by considering a unit of the Great Salt Lake Basin project, that unit embracing the Cache Valley. This Valley contains approximately 175,000 acres of irrigable land south of the Utah-Idaho line. There is at present under irrigation 95,000 acres and about one year out of five there is a serious water shortage in the later summer and fall even in this, one of the best watered valleys in the inner mountain countries. The cost of soring water for the supplemental irrigation of the lands of this valley is beyond the financial resources of any single irrigation company, and in fact is of such magnitude that to make it effective it has to become a community problem.

To operate as a unit would require a suitable single parent organization, such for instance as an irrigation district or water conservancy district. The proper utilization of the waters of the community would demand the use of the water from those lands which could be best served by any stream or spring irrespective of present ownership when considered in conjunction with the supplemental supply. This, therefore, would involve an exchange of water rights to work out an adequate system; it would require a comprehensive view of the agricultural and engineering problems of the entire valley; it would demand a comparison of the total and unit returns for the lands now under irrigation it would require a comparison of estimated returns with present returns based upon the additional cost under the proposed development. The study would not only involve the individual farmers in the single canal company but would have to consider the community as a whole. The manager, the state, and the community would be interested from the standpoint of increased production and wealth, as well as bringing under irrigation additional acres.



The Division of Agricultural Engineering is working on problems of water measurement as an important phase of irrigation research. This is the new type "Hoff" meter for measuring stream velocities, designed and developed by E. J. Hoff, of the Division.

Various types of measuring devices are continually being developed and tested by the Division. This is an improved Venturi Flume, with 3-foot throat section, installed on American Beet Sugar Company's farm, near Fort Collins, Colorado.

NO QUESTION of colonization in this valley, or serious problem of financing the new settlers would be involved. There has already been determined the type of agriculture best suited to this region and the possibilities of the valley from a productive standpoint are proven. Estimates can be based upon past accomplishments—upon facts rather than upon assumptions and guesses.

(*Continued on Page 33*)

Mead, in Letter to Chester Rowell, Comments on River Problem

THE RELATION of the proposed all-American canal to the probability of Colorado River legislation, and the importance of the international conflict of interests on the Colorado River and the Rio Grande, are emphasized from a most interesting point of view in a letter from Elwood Mead, Commissioner of Reclamation, to Chester Rowell, influential California publicist and political power, which has recently been made public.

Dr. Mead's letter, in part, reads as follows:

"The secretary's recommendations in the first letter and reiterated in his second, that the all-American canal should be coupled with negotiations with Mexico, has a much more vital relation to the passage of this legislation (the Swing-Johnson bill) than the people of Southern California seem to realize.

"For months past, correspondence has been going on between this country and Mexico relative to an international water-right agreement on the Rio Grande and Colorado rivers. On the lower Rio Grande there are 200,000 acres of land on the Texas side, irrigated with water 85 per cent of which comes from Mexico.

"Mexico can use all the water rising within its own territory on its own land. But to save these American farmers and the millions invested we must induce Mexico to recognize the rights of prior users in this country.

"Over on the Colorado the situation is reversed. There are 200,000 acres of land irrigated in Lower California with water that comes wholly from the United States. I believe the prior rights in both cases should be protected, but we can only do that through an international agreement by which both of these streams will be dealt with together.

"It is of the utmost importance, therefore, that nothing be done to interfere with these negotiations.

"To announce that the government was going to build an all-American canal without any consideration of the rights of Mexico in the Colorado is, to say the least, lacking in tact or courtesy. That all-American canal, connected with the reservoir, would enable all the water to be taken out before it reached Mexico. Building it with no effort to reach an understanding would be regarded by Mexico as evidence of intent to do this.

"This is not conjecture. We know how this matter is regarded at the Mexican capital. At present the Imperial valley is being irrigated and the levees protecting its lands from overflow are being operated and maintained through the courtesy of the Mexican government.

"An act of aggression on our part, such as some of the people of California seem to favor, might lead to a reprisal on the part of Mexico that would interfere with the operation of these works.

"Imperial valley depends on and must depend on the operation of the canal and levee system for several years. It seems much more sensible, more courteous, therefore, to approach this matter as the ecretary has done. It will help to prevent destructive reprisals which Mexico is capable of putting into effect both on the Rio Grande and the Colorado. The people of the Imperial valley, or of Los Angeles, do not seem to realize this precarious situation.

"There is another phase of this matter. The people of the east, to whom Imperial valley is remote, have important relations with Mexico in oil, lands and trade. Immediately after the secretary's first letter I received a letter from a former secretary of the interior expressing a belief that the secretary's first letter did not give proper consideration to Mexico's rights and he insisted that our willingness to act fairly should be made so plain that no one could question it.

"What the secretary has said does not menace the building of the all-American canal if needed. It has made influential friends for the legislation in this part of the country."

Colorado and Rio Grande--Rivers of Doubt

(*Continued from Page 18*)

sites can not be utilized, nor the title to the water which is stored protected, without a treaty. A special water treaty with Mexico is therefore the fundamental need of the American farmers on the lower Rio Grande.

The right to the water now being used can not be protected, nor can their increasing needs be provided for except through a new treaty. The American need for such a treaty is pressing. On the other hand, Mexico has no immediate concern in such a treaty.

It is true that, ultimately, neither country can enjoy the fullest benefits from the stream without some mutual agreement which will permit of a comprehensive system of storage and distribution, but until Mexico has occasion to use the resources of the Rio Grande, she may remain indifferent and postpone any settlement until the United States is forced to concede terms that may be satisfactory to her but disastrous to American interests.

When, in the course of the diplomatic correspondence which arose out of the creation of the American commission on the equitable use of the waters of the Rio Grande a little over a year ago, Mexico proposed that the inquiry be extended to include the Colorado river as well, a new situation was brought about. The remarkable situation which exists on the Colorado has been so widely discussed in late years, that it is unnecessary to go into details here.

Undoubtedly Mexico, at the present time, is in an even more strategic position on the Colorado than on the Rio Grande. However, if the works which are contemplated in the proposed Colorado River bill are carried into execution, the physical control of Colorado water will be transferred absolutely to the United States. Mexico occupies a very different position on that stream, inasmuch as she has an extensive development dependent on its water resources. The authorization of an All-American canal would create a menace to this development unless Mexico's present use of this water should be made secure by treaty.

In view of this new situation, Texas is looking toward the far west with considerable interest. It sees in the All-American canal provision of the Colorado River bill an opportunity to place the Rio Grande question on a basis where it will not be quite so one-sided. The United States must rely largely on the principle of priority to protect its Rio Grande development, while Mexico must invoke the same principle to protect its Colorado river development. By disposing of international questions on both streams in one settlement some common principle could be applied which would properly recognize the equities of both countries.

If those states most interested in securing the development of the Colorado, with the all-American canal, are willing to consider a friendly alliance of interest with Texas, and concede the common interest which the two regions have in a treaty settlement of Mexico's interests in both the Colorado and the Rio Grande, the latter state is disposed to look upon the All-American canal with almost a personal interest. In that fea-

ture lies the hope that this country may be able to enter into negotiations regarding both of these streams upon something like equal terms with Mexico.

IT SEEMS to be generally conceded that Mexico is to be given every consideration that justice and equity demand, when the final disposition of her claims to Colorado River water is made, even though the new works which are contemplated might make it physically possible to cut off her water supply completely.

While the rules of international law might justify such a course, international comity might not. By a joint settlement of both streams, therefore, no sacrifices are demanded of American interests on the Colorado that would not be conceded in an independent settlement. But thereby Mexico would be placed in a position where she must adopt the same broad and liberal attitude toward American equities in the Rio Grande.

In short, by a joint settlement, both countries would be impelled to take a fairer view of the other's claims than would be the case if each stream was to be disposed of by independent treaties, each of which would have to be approached from a position where one party had the advantage.

Texans do not feel that they are the sole beneficiaries of this suggested community of interest. From this point of view, the problems of both streams are lifted out of the realm of purely local concern and are given national significance and scope. National interest can not tolerate a foreign menace and domination over two of the most productive and fertile sections on the continent. So long as the present status remains, the continued existence of these two similar, but widely separated communities, remains in doubt. The Colorado River bill, with its All-American Canal provision, takes on added significance from the standpoint of the nation at large. Without some adjustment of the problems of these two rivers they are certain to become more and more a source of friction between this country and our neighbor on the south.

If Texas be joined with the proponents of the Colorado River plan in ties of common interest, it can bring to the union a large measure of prestige and influence in Congress. With its 18 members in the House, including the ranking Democrat and dean of his party, Hon. John N. Garner, who represents the lower Rio Grande district, probably no state wields a greater influence on the Democratic side of the House than the Lone Star State. In the possibility of a union of forces of this kind, between these two sections of the irrigated southwest, there are implicit far-reaching potentialities for influence upon the shadow of doubt that now hangs over these two great international rivers.

Imperial District's Directors Dispute Over Employees

C. W. Brockman, minority member of the Board of Directors of the Imperial (California) Irrigation District, precipitated an interesting situation in March when he introduced before the board a resolution calling for the reduction of salary or discharge of seven employees of the district, whose duties he asserted to be partly or mainly political ones. Mr. Brockman's action followed the dismissal of certain employees of the district, who were discharged some weeks ago following the ruling of a California court which held that the hiring of employees to influence legislation was outside of the legal powers of an irrigation district.

Mr. Brockman's resolution did not come to a vote before the board of directors, the majority of whom are not in agreement with him, failing for the want of a second. An answering resolution, introduced by another member of the board in response to the Brockman resolution, however, was seconded and passed.

In the latter resolution, which constitutes a rejoinder to some of the allegations made by Mr. Brockman, the board denies that the duties of the employees in question are wholly, or in any considerable part political, setting forth at length the nature of the respective services performed by each, and asserting that each of the men in question is serving the district efficiently and well. In amplification of these denials, the resolution shows that the monthly payroll of the district has shown a steady decrease since the recent re-organization, as compared with corresponding months of the previous year.

The employees named in the Brockman resolution are: C. M. Berry, purchasing agent; Charles L. Childers, chief counsel; A. C. Finney, associate counsel; A. E. Kellog, deputy collector; Carleton D. Joy, assistant secretary; John W. Scott, assistant purchasing agent; George Whitlock, right-of-way.

Whose Water

(*Continued from Page 12*)

in Shasta County, from which about 2200 acres are irrigated.

West Fork of Carson River in Alpine County from which about 5000 acres are irrigated.

Hat Creek in Shasta County, from which about 2500 acres are irrigated.

Oak Creek in Inyo County, from which about 1700 acres are irrigated.

Burney Creek in Shasta County, from which about 2500 acres are irrigated.

One proceeding referred by the superior court of Lassen County and including the water rights covering about 3200 acres of land irrigated from Red Rock Creek, was abandoned after it became apparent that a final settlement could not be made within any reasonable time because of involved land ownerships and other pending litigation.

The pending adjudications cover all water rights on the following stream systems:

Stanislaus River in Alpine, Calaveras, Tuolumne, Stanislaus and San Joaquin Counties, from which about 150,000 acres are irrigated.

Whitewater River in Riverside and San Bernardino Counties, from which about 18,000 acres are irrigated.

North Cow Creek in Shasta County, from which about 1800 acres are irrigated.

Oak Run Creek in Shasta County, from which about 500 acres are irrigated.

Shasta River in Siskiyou County, from which about 40,000 acres are irrigated.

Owl Creek in Modoc County, from which about 3000 acres are irrigated.

Soldier Creek in Modoc County, from which about 1900 acres are irrigated.

As indicative of the beneficial results accomplished through adjudication proceedings, it should be noted that the Division has undertaken five proceedings in Shasta County alone, all of which were initiated by court reference. Three of these, covering the North Fork of Cottonwood Creek, Hat Creek and Burney Creek, were settled by agreement of the claimants after the physical facts had been determined and presented in the form of maps and reports. In the other two cases, covering North Cow Creek and Oak Run Creek, tentative allocations of the water supplies have been agreed to by all of the claimants, with the understanding that the waters are to be distributed in accordance therewith throughout the 1926 irrigation season by a water master, to be appointed by the Division, and it is believed that such action will afford the basis for equitable final settlement in the two cases.

In recent years there has been an ever-increasing demand upon the Division for information relative to the adjudication procedure. Requests for information have been received from all parts of the state, and from parties contemplating new developments who realize that the success of their plans will be dependent upon a knowledge of the extent of vested rights and proper steps to protect the same, as well as from the owners of old vested rights who fear encroachment by new appropriations. It seems certain, therefore, that as the development of the water resources of the state proceeds, an increasing number of water users will avail themselves of the adjudication procedure provided in the Water Commission Act, in order to establish titles to their water rights and to make such titles secure.

THE HYDRAULIC DIGEST

A Monthly Bulletin Board of Brief Facts and Events from Far and Near

Reject Santa Cruz Bids

All bids tendered on the Santa Cruz, New Mexico, irrigation project, which were opened on March 11, were rejected as being too high, and another call for bids was issued. The estimated cost of the project is $250,000.

Vote Water Bonds 10 to 1

Residents of Willowbrook, near Long Beach, in Southern California, voted their approval of the issuance of $70,000 in bonds for the construction of a water system, during March, by a majority of ten to one.

Senate Passes Norris Bill

The "Norris Bill," providing for closer co-operation between the federal department of agriculture and the various states in the protection of forest lands, reforestation, and extension of the national forests, has passed the Senate and goes to the House for action.

Everett to Vote on Bonds

Voters of Everett, Washington, will ballot in May on a proposition providing for the acquisition, by the city, of Flowing Lake and watershed, construction of a three-mile pipe line from Flowing Lake to the Sultan supply line, and issuance of $260,000 in revenue bonds to accomplish the work.

Refunding Issue Anticipated

The Payette-Oregon Slope Irrigation District, Oregon, is planning to issue a refunding bond issue in exchange for the outstanding issue of $64,000, which becomes due this year and which the district is not expected to meet. Carstens & Erle, Seattle firm which originally purchased the bonds, has agreed to circularize the holders of the bonds urging acceptance of the refunding issue.

Start Girard Water System

Department of Water and Power of the City of Los Angeles has started work on the construction of a water system for Girard, San Fernando Valley community, which will cost $275,000. The system will include 27 miles of pipe, varying in size from four to twenty inches in diameter, and a reservoir of 284,000 gallons capacity.

Concreting Work Finished

Concreting of canals of the Roosevelt Water Conservation District (Arizona) has been suspended for the season, the last canal to be lined being the south canal, main intake for the south side of the project. Within a short time the main pumping plant of the district will be in regular operation. Concrete lining operations will be resumed next winter, when the big job will be completed.

Kittitas Plans Advanced

It was announced by the Yakima office of the Bureau of Reclamation during March that the development of the $7,500,000 Kittitas high line project would be directed as a separate unit, divorced from the control of the Yakima office. The soil survey work of the project has sufficiently progressed to justify the statement that the irrigable acreage under the project will amount to 75,000 acres.

Yakima Buys Water Properties

City commissioners of Yakima, Washington, have authorized the sale of $100,000 of general obligation bonds, the funds from which will be used in the purchase of the Oak Flats site, proposed intake, rights of way and reservoir site. It is expected that this step will remove the objections which resulted in the recent failure to sell the issue of the city's $1,050,000 worth of utility bonds based on the values to be created in the new water system.

Auburn System Near Ready

The Coal creek water system, now being constructed for the city of Auburn, Washington, will be completed by May 1st, according to a report by J. A. Fallgreen, city engineer. The project is well ahead of schedule and will be finished comfortably ahead of the date originally set. The city will celebrate the completion of the system by a special municipal holiday, in which opportunity will be given for inspection tours over the whole system.

No Pay, No Water, Says Mead

Elwood Mead, Commissioner of Reclamation, announced on March 30 that water users on federal reclamation projects who are more than one year in arrears in their payments on water charges will not receive water this season until their claims have been satisfactorily adjusted with the government. He stated further that the notes of individuals or of the irrigation district, or crop mortgages will be acceptable as payment.

Pine Flat Report Near

The scheme for the creation of a super-conservation and irrigation project in the central San Joaquin Valley, California, commonly called the Pine Flat project, is nearing the point where definite steps may be taken leading to the calling of a bond election, it is stated, as the preliminaries of a survey by a special engineering committee, headed by George L. Swendsen, were nearing completion. This committee has been at work since September, 1925, in the compilation of data on the resources of the Kings River area, and expects to report in April.

Urge $2,000,000 Reservoir

Construction of a large reservoir and dam in the Glen Park district of San Francisco, for the protection of the city from possible failure of delivery by the Hetch Hetchy project has been urged by M. M. O'Shaunessy, city engineer of San Francisco. Pointing out that present reservoirs within the city limits would provide water for the needs of San Francisco for only three days in the event of temporary failure of delivery of water, Mr. O'Shaunessy recommends the construction of a dam of 500,000,000 gallons capacity, with an estimated cost of $1,750,000 for the dam alone.

Ojai Valley Plans Project

Plans for the development of a $2,000,000 irrigation project to supply water to lands in the upper Ojai (California) Valley were revealed in March when application was filed with the state division of water rights seeking permission to appropriate 30,000 acre-feet of water in the Santa Clara River watershed. Application was filed by Guy T. Stetson and Henry S. Nixon as trustees for the Ojai Irrigation District. The plans for the project call for the building of a dam in the Sespe Canyon and tunnel to carry the water through the mountains to the Ojai.

AUTOMATIC DEVICES FOR

WATER MEASUREMENT *and* CONTROL

SPARLING METERS

Attach to 2 inch to 60 inch pipes and record direct in gallons, cubic feet, acre-feet or miner's-inch-hours. Good for any pipe pressure 0 to 150 lbs. With "METROGRAPH" attachment they furnish also a graphic hour-by-hour chart of flow fluctuations.

"SENTINEL" RECORDING GAUGES

For recording the varying depth of flow, not exceeding one foot, over open weirs of any length of crest. Daily or weekly record sheets.

SPARLING RIVER AND RESERVOIR STAGE RECORDERS

Worm-geared, ball-bearing action reducing 10 to 30 foot fluid range on twelve inch flow-charts. Coil spring tension on graduated float tape allows very accurate setting and visible readings.

SPARLING DIFFERENTIAL ORIFICE HEIGHT RECORDERS

Indicate and record the difference between approach and discharge levels on opposite sides of orifices, measuring gates, submerged weirs, Venturi flumes, etc. Maximum allowable variation of primary levels, 5 feet—of differential height, 12 inches.

SPARLING CONSTANT DISCHARGE VALVES

For reservoir and canal outlets where a uniform flow is important. Built in 8", 16", and 24" flanged pipe sizes.

AND

Many other special pieces of apparatus for simplifying and systematizing irrigation water problems. Write to us regarding your particular requirements. For fourteen years we have specialized exclusively on the manufacture of water control equipment.

Glenn-Colusa District May Build $2,000,000 Dam

Manager Durbrow Announces Plans for Project to Generate Power and Save Pumping

Construction of a $2,000,000 diversion dam on the Sacramento River (California) near Hamilton City, resulting in the generation of 13,000 horsepower and the elimination of the present pumping plant of the Glenn-Colusa Irrigation District is contemplated in an announcement made in March by William Durbrow, general manager of the district.

In his statement, Mr. Durbrow states that the application for permit to appropriate 300 second-feet, which the district has filed with the state Division of Water Rights, is merely a preliminary move paving the way for a complete investigation of the feasibility of the project.

His statement follows:

"The Glenn-Colusia Irrigation District has made an application to the Division of Water Rights for a permit to appropriate 300 second feet of the flow of the Sacramento river for power purposes.

"The proposed project would entail an expenditure of $2,000,000. The gravity diversion dam would be put in across the Sacramento river at the present location of the pumping plant of the district near Hamilton City.

"The upper nine miles of the district's central canal would be enlarged, and approximately at Nine Mile the water would be dropped back into the Sacramento river through a power plant, which would give a drop of approximately thirty-eight feet and the generation of about 13,000 horsepower.

"The application for a permit to the division of water rights is in this case simply a preliminary step to an investigation as to the feasibility of the project.

"While there has been no navigation of this portion of the river for some ten or fifteen years this project would undoubtedly bring up a conflict as to the question of the navigability of the upper regions of the river. The project, however, does not necessarily mean the abandonment of such navigation, but might be used as a unit in the canalization of the river.

"The Glenn-Colusa Irrigation District's chief interest in this matter is the possibility of paying for a gravity diversion dam through the sale of power making for the district a great saving in its present pumping costs.

"Such a project would also be of interest to other districts taking water out of the Sacramento river on both sides, which through the diversion dam would be enabled to get gravity water to their lands rather than through the present costly process of pumping from the river.

"While no plans have as yet been made as to the use of the power to be generated by this plant the preliminary estimates will be based upon the sale of such power at a going rate to some distributing company."

Suggests Simple Method of Determining "Draw-Down"

Madera Man Uses Weighted Rubber Tubing as Apparatus; Lungs Do the Rest

D. Stephenson, a Madera (Calif.) plumber, has several inventions to his credit, the latest of which is a simple method of determining the "draw-down" in a drilled well, in which a deep well turbine has been installed.

Mr. Stephenson and the Apparatus

Instead of the more expensive and complicated method of using a hand-pump, in conjunction with a vacuum or pressure gauge, or any one of several types of electrical contrivances, ¼-inch rubber tubing, weighted with two feet of copper tubing, is "fed" into the space between the pump and the well casing, while the pump is idle.

As the approximate water-level in the well is known, the tubing is lowered to that level and, by either blowing or sucking, the exact point of contact with the water is easily determined.

The tubing is marked at this point and the pump is started. After the pump has been running for several minutes, or for a sufficient time for the water to have lowered to its "pumping level," Mr. Stephenson again lowers the tubing—sucking at intervals at the end of it—until the tongue detects a slight vacuum. The tubing is again marked.

The distance between the two marks is the "draw-down." The distance from the first, or lower mark, to the lower end of the tubing is the static head and the distance from the second, or upper mark, to the lower end of the tubing is the "pumping head"—less friction.

Irrigation Districts Association Meets at Merced

(*Continued from Page 13*)

Irrigation District, which seeks to enjoin the district from expending any funds of the district in presenting any case before any legislative body, and on his suggestion, the Association authorized its executive committee to file a brief on behalf of the Association in this case.

In the interest of forest conservation, the Association adopted the following resolution:

Resolved, That we are opposed to the ruthless denuding of the forests on the upper watersheds of our rivers and urge the Department of Parks and Forest Service of the Government to take such steps as may be necessary to conserve the timber and brush; to be more strict in the issuing of permits granting to lumber companies the right to cut timber, to the end that the run-off will be spread over a longer period during the summer season. And be it further

Resolved, that the secretary send a copy of this resolution to our representatives in Congress and to the heads of the Park and Forest Services.

Opposition to a tax on the revenues of publicly owned utilities, proposed before the last California legislature, was voiced in the following resolution:

Whereas, There was before the last Legislature of the State of California, Assembly Bill No. 4 and Senate Bill No. 7, providing for a tax upon the gross revenue of publicly owned utilities, and

Whereas, It is understood that the so-called Farm Legislative Committee will sponsor this same movement during the coming session of the Legislature,

Therefore be it resolved, That the Irrigation Districts Association of California, in session on this 12th day of March, 1926, again go on record as unequivocally opposed to such a measure on the following grounds:

1st, That it would be a serious blow to the principle of public ownership. The fact that public utilities supplying water are exempted shows that its authors are not consistent and do not have faith in the arguments which might be put forth to support the measure.

2d, That the whole theory of this amendment is inconsistent with public ownership and operation of public utilities. The public would be taxing itself to run its own business.

3d. That it is apparent by this amendment that, had all public utilities been included, it would have received little support. Therefore, apparently, only those were included that would work a benefit to now privately owned utilities that are supplying the public with electric power and other such services.

4th. That the power companies pay only seven per cent of their gross income in lieu of all other tax. The people living in communities owning and operating their own public utilities pay all the County, City and Irrigation tax. Therefore, if this amendment were to pass, it would be clearly a case of double taxation and a penalty on every community owning its own utility.

5th. That the rates which the private utility may charge for service are fixed by the Railroad Commission at a figure which will insure a return of 8 per cent on their investment, while no such protection is given publicly owned enterprises.

A plea for a more optimistic picture of federal reclamation, and an implied criticism of publicity that emphasizes the difficulties and failures of reclamation policies, were approved in the following resolution:

Whereas, Nationwide publicity regarding the United States Reclamation projects is prejudicing the public mind against Western reclamation and

Whereas, we believe the public is entitled to know some of the accomplishments of the Bureau of Reclamation from official sources, and

Whereas, we believe in the original plan of the United States Reclamation Service to perform a definite and necessary public improvement work in the West,

Therefore be it resolved, by the members of the Irrigation Districts Association of California, representing 4,000,000 acres of irrigated and irrigable land in California, in annual session assembled at Merced, California, this 12th day of March, 1926, that this association go on record as requesting such a definite program of publicity initiated by the Bureau of Reclamation as will fully and completely reflect the results achieved as a whole during the past twenty-three years by the United States Reclamation Service, and be it further

Resolved, that copies of this resolution be forwarded to the Honorable Calvin Coolidge, President of the United States, to Hon. Hubert Work, Secretary of the Interior, and Hon. Elwood Mead, Commissioner of Reclamation.

Indo-China Has Ambitious Irrigation Works

Indo-China has undertaken agricultural irrigation on a large scale. The works include a great dam in the delta of the Thanh-Hoa, which empties into the Gulf of Tonquin. It was completed in January, 1926, having been begun in 1918. It will be the largest irrigation system in the East except those in India. Besides the dam there is to be a chain of navigable canals sixty-eight miles long, 320 miles of large ditches and 970 miles of minor ones, not all of which are completed. The expenditures so far have been $2,300,000.

The Thanh-Hoa runs southeasterly along the foothills of the Song-Ma Mountains, the boundary between Tonquin and Annam. These heights are divided by valleys through which run streams that are dry in summer but in winter are raging torrents. It is to collect and combine these waters that the irrigation plant has been constructed. It is expected that conservation will produce water in plenty to irrigate the northern part of Annam during the dry season, which comes in June, July and August. They are expected to provide for the irrigation of 150,000 acres.

Rice has been the chief product of Annam, but of recent years cotton has been raised with success. The new irrigation works will make it possible to increase the area devoted to cotton and to aid the cultivation of sugar cane as well as rice in a densely populated part of the province.

Republic Electrical Liquid Level Recorders

These instruments have a wide application wherever the correct knowledge of liquid supply in tanks, standpipes, reservoirs, irrigation, etc., is desired.

The Reading instruments can be either Indicating, Recording or both (as in the above illustration showing reading instruments installed at Endicott-Johnson Corporation Water Works). The Reading instruments can be located at any distance from the place where pressure or level record is taken.

MANAGEMENT

HOW MANY INCHES OF WATER IN A BUSHEL OF WHEAT?

By W. H. SNELSON

Senior Irrigation Specialist, Dominion Irrigation and Reclamation Service, Calgary, Alberta

DUTY OF WATER investigations extending over eight years, 1918 to 1925, inclusive, conducted at the Dominion Irrigation Experiment Station at Brooks, Alberta, Canada, have given results which are partially illustrated in the diagram on this page, showing the water requirements of Marquis wheat, as determined in the tests.

For the purposes of the tests this wheat was grown each year under several different conditions of soil fertility in order that data could be obtained relative to the effect of soil fertility upon the water requirements of the plant. The following table shows the position the wheat crop occupied in each of four different crop rotations.

Rotation D.—Red clover two years, *wheat,* barley.

Rotation A.—Alfalfa five years, potatoes, *wheat,* flax.

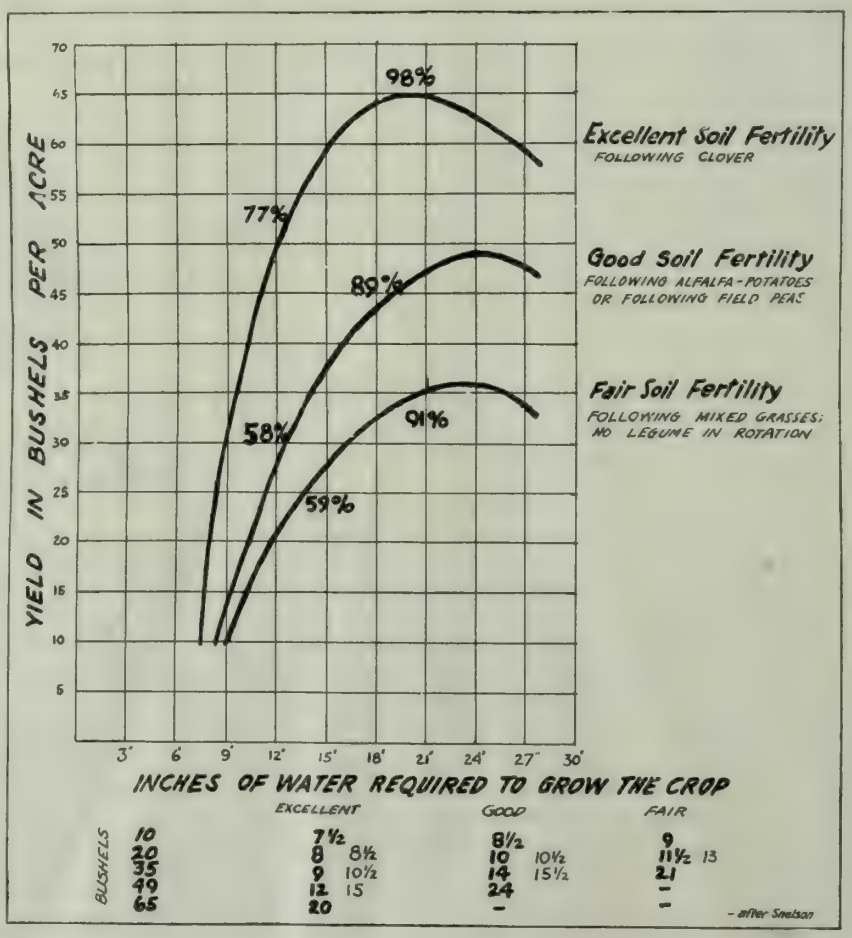
Rotation E.—Peas, *wheat,* oats, barley.

Rotation C.—Mixed hay grasses three years, potatoes, barley, *wheat.*

The accompanying diagram shows that under excellent conditions of soil fertility such as obtained (Rotation A) following the plowing under of a two-year stand of red clover, a maximum yield of 65 bushels per acre was obtained with a total depth of water used (precipitation through growing season plus irrigation applied plus stored soil water used) of 20 inches.

Under good conditions of soil fertility such as obtained following alfalfa-potatoes (Rotation A) or peas (Rotation E) a maximum yield of 49 bushels per acre was obtained with a total depth of water used of 24 inches.

Under fair conditions of soil fertility, such as obtained following grass-potatoes-barley (Rotation C) a maximum of 36 bushels per acre was obtained with a total depth of water used of 24 inches.



THE TABLE shown under the diagram gives in heavy-type figures the inches in depth of water required to produce given yields of wheat under excellent, good, and fair conditions of soil fertility when the water was applied in irrigations of four inches depth each. The light-type figures give the depth required when the water was applied in six-inch irrigations.

A yield of 35 bushels per acre required 21 inches of waer under fair conditions of soil fertility but only 9 inches of water under excellent conditions of fertility.

The figures on the curves give, opposite the use of 12 inches and 18 inches of water, the percentage of maximum yield obtained by the use of these depths. Twelve inches of water produced 58 per cent of the maximum yield on good fertility and 77 per cent on excellent. Eighteen inches produced 89 per cent on good fertility and 98 per cent on excellent.

This information will be of value to growers of wheat under irrigation, who are sometimes in doubt as to how much of the optimum amount of water they can use with economy. There would be no question in the irrigator's mind as to whether, having supplied the crop on excellent soil with 12 inches of water, it would pay to ap-

ply 6 inches more, for in so doing he would obtain an additional yield of 15 bushels per acre at the cost of one irrigation. On the other hand, having supplied the crop on the fair soil with 18 inches of water to obtain 33 bushels per acre it would be a question of weighing the cost of an additional irrigation against the three additional bushels to be obtained.

This diagram emphasizes the necessity of maintaining a high standard of soil fertility where grain is grown upon high priced irrigated lands. One and one-half acre-feet of water produces 3.6 bushels per acre-inch in the excellent soil and but 1.8 inches per acre-inch in the fair soil.

The soil at the Brooks Station is silt-loam. The mean temperature and precipitation for the growing season, April to December, is 56.6° F. and 8.32 inches (1915 to 1925).

Are Your Tools Right?

The practical irrigation farmer needs a few essential tools, in order to work to good advantage, points out a writer in THE HIGHWAY MAGAZINE. The executive and adviser who is interested in improving the efficiency of the water user should see that he is provided with these implements. Along the essential items is a land level for finishing off all fields before seeding. This can be simply made of plank two inches thick by eight or ten inches wide, 16 to 20 feet long, and altogether eight feet wide, for four or six horses. Pulled across the field, it will fill all dead furrows, will level back furrows, and fill all voids. This machine will also do considerable general smoothing and clod crushing.

Next a ditcher of some kind is needed. A common 18-inch lister or double plow makes a very good lateral. One or two furrows with a common plow, and then a trip through with a go-devil or a log will do the work. A good ditcher can be made from two, a right and left, 14-inch walking plows bolted together, and pulled by four horses.

There are various systems of dams, the farmer should decide which is best suited for his use. A plan which has been found very good, is to make provision for a number of adjustable metal dams when making the ditches. This prevents loss of water and time in the rush hours of irrigation. A good point, not always remembered, is to place the dams in the high places. Avoid the low spots. They will take care of themselves when it comes to getting their share of the water. Keep the laterals clean. A clean lateral means water saved, and on an irrigated farm, water

LAYKOLD
EMULSIFIED ASPHALT

SANDY ditches can be easily waterproofed by pouring Laykold directly on the banks, mulching it in well by rake, and then finishing off with a smoothing iron. This type of lining is inexpensive, and will give satisfactory results for one or two seasons, after which it can be replaced with a permanent asphaltic concrete lining.

IRRIGATION ENGINEERING

By ARTHUR POWELL DAVIS, D. SC.
Chief Engineer and General Manager, East Bay Municipal Utilities District; formerly President Am. Soc. C. E.; formerly Director and Chief Engineer, U. S. Reclamation Service.

AND

HERBERT M. WILSON, C. E.,
Mem. Am. Soc. C. E.; former Chief Engineer and Irrigation Engineer, U. S. Geological Survey.

Seventh Edition, Revised and Enlarged; Total Issue 12,000

THIS IS a rewritten and rearranged edition with much new material added. The principal difference introduced is the treatment of soils, plant food, operation and maintenance, and other lines of work where the duties of the irrigation engineer come in contact with the irrigator, such as in the preparation of land, the duty of water and its application to the land. A bibliography of standard works is given at the end of each chapter. 640 pages. 6 by 9. 249 figures and illustrations. Cloth, $4.50 net postpaid. Remittance must accompany the order. Allow from one to two weeks for transmittal of order and shipment from the publishers.

IRRIGATION PRACTICE *and* ENGINEERING

By B. A. ETCHEVERRY,
Professor of Irrigation Engineering, University of California.

In three volumes—the most comprehensive work in the field. A wealth of information of both practical and informative value for everyone interested in water development and conservation. Prices are net postpaid and remittances must accompany order. Allow from one to two weeks for transmittal of order and shipment from the publishers.

Vol. 1.—Uses of Irrigation Water and Irrigation Practice.....$2.50
Vol. 2.—Conveyance of Water..... 4.00
Vol. 3.—Irrigation Structures and Distribution System..... 4.50

PIPE

Both USED and NEW--At a SAVING to YOU!

WHENEVER and wherever you need pipe of any size or dimension, Pacific can serve you and save you money, too. For general farm and irrigation purposes, Pacific Reconditioned Casing is a real bargain. Absolutely guaranteed. Every length straight and clean with new threads and couplings, each protected from damage in shipping by special steel protectors.

Every length rattle-tested and steam pressure-tested as proof against weakness; then dipped in a special non-tasting hot asphaltum which resists alkali and corrosion. This adds years to its life. Nowhere else in the West, except in the Pacific plant, can used pipe be so thoroughly reconditioned and then sold at such low prices.

saved, means money saved. Main laterals should be cleaned twice a year.

Last, but not least, the irrigator must get a good honest man who will use his head as well as his hands, and give him a good shovel. The shovel should not be too heavy, fairly straight, with small shank and sharpened daily or more often. Tell your man not to try to dig up the whole farm, but just keep the oncoming water blocked.

Standard Irrigation Work Is Brought Up to Date

Samuel Fortier's well-known work "Use of Water in Irrigation," first issued in 1915, and revised and printed in the second edition in 1916, has been just issued in the third edition, in considerably revised and amplified form. Dr. Fortier's book has been recognized as a standard work for the guidance of the application of irrigation water since its first appearance, and its modernized version will undoubtedly enable it to hold its place of popularity on the reference shelf and the executives' desk, and in the farmer's library and the class-room.

In the preface to the third edition, Dr. Fortier says:

"During the decade that has elapsed since the first edition of this work was published, the practice of irrigation has been much improved, the farmers' part in irrigation development better understood and appreciated, and the fundamental principles of irrigation farming more fully elucidated.

"To record these changes aright, and to present in summarized form the knowledge that has been gained on different branches of the subject since 1915, it has been necessary to add a number of new articles and to rewrite and enlarge much of what has appeared in the earlier editions.

"The author hopes that this latest effort on his part and of those who have been associated with him will bear fruit and that this revised and enlarged edition will continue to be a safe guide to irrigation practice in this country."

In the revision, Dr. Fortier has added a large amount of thoroughly up-to-date material, embodying the latest investigations in many departments of the broad subject of the use of water. Only the discussions of the broad principles of irrigation have been left unrevised; the statistical matter has been entirely worked over, taking the latest census enumeration as its basis in most cases, while the references to modern practices and present-day knowledge is written entirely from the point of view of 1925.

Copies may be obtained through MODERN IRRIGATION. Price $3.00.

Keeping Pace With Irrigation

(*Continued from Page 23*)

There would be provided by such development irrigated lands for supporting additional people as well as the better supporting of those already there. The financing of the work as a whole would be relatively easy and simple from the very fact that the danger of failure is reduced to the minimum and the land can be put to work immediately when additional water is available.

This is only one example of many that could be cited, showing the possibilities of this line of development. There are instances where a little additional capital would provide for the enlargement of existing reservoirs that would bring the present irrigated lands up to full production. In other localities this additional capital might be used in replacing temporary structures with permanent ones, thereby reducing the annual operation and maintenance costs and so on throughout the category.

In one district in Utah, water is raised to a height of 325 feet by means of pumps for irrigation. At the north end of this district on the same side of the hill there is flowing down from the mountains above a stream of water which is used for the irrigation of lands lying for the most part below those lands covered by the pumping plant. In other words, the water in this stream is flowing down through at least 300 or more feet in elevation before being raised by means of the pumps. An exchange of water in this case would make both projects feasible and economically safe. Such cases as this would require, undoubtedly, the assistance of outside aid in bringing about the desired transfer of water rights.

Such work as this kind of development coupled with our efforts to help solve the individual irrigation problems, and coupled with our endeavor to coordinate the investigational reclamation work of the western states in those problems of general and basic value, offers sufficient opportunity for the future efforts of this division.

Our division is not a large one and funds at our disposal are quite limited. We feel, however, that this division has returned to the people in real value many fold the funds expended. Our endeavor in the future will be as it has been in the past to be of more and more service in helping solve the every day problems of the farmers and rural districts that are making their homes upon irrigated lands, that their lot in life may be more prosperous and contented.

You *Name the* Load
We *Make the* Pipe!

SINCE concrete pipe (as made by Bent) came into its own, engineers question no longer its striking advantages for a great variety of uses. *But*—a concrete pipe installation is either a mediocre or an eminently superior job of work, depending upon who fulfilled the contract.

Many trade names have become hall-marks of tradition, that serve as an unerring guide to discriminating buyers. Today the name "BENT" on a joint of Concrete Pipe marks it as a strictly finely made product. The same care and skill is exercised in its manufacture, and in the laying of the line, as though every future contract depended on *that* job meeting the fullest requirements of specifications—*and more.*

Let us give you a "concrete" demonstration of what we mean by "Bent" Service.

WITH THE WATER COMPANIES

Of Interest Expressly to Water Works Engineers, Superintendents and General Managers

STREAM POLLUTION IS A NATIONAL PROBLEM

By NATHAN T. VEATCH, Jr.*

PROTECTION of our streams, and other bodies of water as well, is nothing more or less than the protection of a national resource, in fact, one of our most valuable national resources, since it concerns the all important question of public water supply and therefore, concerns all city dwellers in locations where ground water supplies are not available. Some industries are entirely dependent on reasonably pure stream water and all industries are dependent on water supplies of some nature.

By no means the least important feature of this question is the fact that it is becoming more and more acute each year through the increase in urban population, the increase in the number of municipal sewer systems, the increase in industries which produce objectionable trade wastes and in the rapidly increasing number of cities which are being forced to use surface water to get an adequate supply.

The increase in the urban population of the United States is shown in the following table adopted from the U. S. Census which shows that the urban population of the United States in 1920, exceeded the rural by approximately 3 million, and there is every indication that this excess will continue to increase.

	1900	1910	1920
Population of U. S. (million)	76	92	106
Rural, (million)	46	50	51.5
Urban, (million)	30	42	54.5

There seems to be no available authentic data on the number of sewer systems in the U. S. but, based on experience in the central west, it may be stated that at the present time a town of 2,000 without a municipal sewer system is decided exceptional, and that probably 75 per cent of these systems have been built in the past 20 years. It is therefore reasonable to assume that within 20 years, practically all towns of 1,000 and over will be served with sewers. Similarly, there seems to be no available authentic data in regard to the change of municipal ground water supplies over the country to surface water, but again judging from experience in the central west where numerous cities have had to make this change, through inadequacy of ground water supplies, this factor is important.

NATHAN T. VEATCH

THE MANUAL of the American Waterworks Association estimates the number of water works in the United States as 9,850 in 1924, of which 36 per cent are surface supplies. In view of the fact that practically all of the cities in excess of 30,000 are included in the 36 per cent it is probably safe to say that 75 per cent of the urban population of the United States is served with surface water from streams, lakes, or artificial reservoirs, and that approximately half of this number, or 20 million persons, are served from water supplies taken from streams which are subject to pollution from municipal sewage, trade waste, or drainage from barn yards or feed lots.

The present standard of purity as set forth by the International Joint Commission in 1913, in an extensive investigation of boundary waters, considered as safe for surface waters which are to be purified by modern plants, consisting of settling and coagulating basins, filters and sterilizing equipment, demands that "the raw water shall not have objectionable odor, color, or taste, and shall not contain more than 500 bacteria of the intestinal type (B Coli) per cubic centimeter."

Practice has shown that the above is not a bad standard to shoot at although satisfactory water is produced at many places where this standard is often exceeded, but the fact remains that the use of such water is dangerous and puts too heavy a load on the purification plant. This extra burden surely should fall on those agencies causing the pollution, which calls for purification of sewage and trade wastes where pollutions exceed a safe limit. As a matter of fact some of the streams of the country are called upon to furnish water for municipal water supplies at a rate which in the aggregate exceeds the flow of the stream at times. This was true of the Verdegris River in Kansas in the fall of 1917, when the aggregate amount of water used by Kansas municipalities along its course, was approximately three times its flow at the Oklahoma State line.

THE CHIEF source of stream pollution is undoubtedly municipal sanitary sewage which may be made up of anything, but which is reasonably uniform except as to trade wastes.

For the study of stream pollution the character of sewage is customarily reported as solids both in suspension and in solution, as organic matter in the form of total nitrogen and "Oxygen Consumed," and as "Biochemical" or "Biological Oxygen Demand" which last is a measure of the oxygen required to mineralize the organic matter in the sewage.

*A paper presented to the National Drainage Congress at its 1926 annual meeting, Oklahoma City, Okla.

THE name-plate on an "American" pump signifies over fifty years successful solution of the handling and pumping of water.

It is backed by an absolute guarantee that the pump bearing it will give satisfactory service on the job for which it is designed!

Tanning	1 skin	163.3	1,261.0	22
Creamery**	10 lbs. butter fat	.90	7.90	14
Corn Products** refining	100 bushels			500

*Adopted from Table 46. United States Public Health Service Bulletin No. 143.
**Estimated from a number of analyses.

Bulletin No. 143 of the U. S. Public Health Service states that average domestic combined sewage without major trade waste will contain the following constituents in grams per capita per day.

Total Solids, 439; Dissolved Solids, 330; Suspended Solids, 109; Total nitrogen, 11.4; Oxygen consumed, 51.5; Biological oxygen demand, 100.

For a city of 10,000 persons, therefore, 1,000,000 grams or 2,204 lbs. of oxygen will be required for sanitary sewage.

Trade wastes are of course more variable and require special study in each instance. They may range from sawdust which has practically no effect on the water, to wastes from coal tar product work which cause objectionable tastes in waters in several million dilutions of pure water.

Several specific wastes have been studied and found to contain total nitrogen and oxygen consumed as shown in the table on Page 36, which also gives the approximate equivalent of the waste in terms of sanitary sewage.

Generally speaking, therefore, it is possible to convert the pollution by trade wastes into its equivalent in sanitary sewage and from this figure to determine the required dilution or treatment necessary to prevent pollution. The dissolved oxygen in stream water will vary from approximately 14 p.p.m. at 35 deg. F. to approximately 9 p.p.m. at 70 Deg. F. provided the stream is not already polluted and therefore less nuisance is caused by a given amount of sewage in equal amounts of water in winter than in summer.

FROM the above stated figure of 2,204 lbs. which represents the daily amount of oxygen required to mineralize the sewage from 10,000 persons, and assuming that 5 p.p.m. of oxygen may be given up by the stream at any time without causing serious nuisance or damage to fish life, it may be estimated that a flow of 80 cubic feet per second or 8 cubic feet per second per 1,000 population will be ample for dilution. Such calculations are misleading however, and cannot be generally applied since so much depends on the local condition of the stream. In the past some authorities have stated that a flow of 4 cubic feet per capita is ample while recently the Royal Commission in England has recommended a dilution of 27.8 cubic feet per second per 1,000 persons.

Self purification of streams is a factor in this problem, but is badly misunderstood. For instance, we have often heard the statement that the Missouri River purifies itself in 7 miles, but this may or may not be the case. Self purification is a factor of time, since certain chemical and biological changes must take place and therefore, the velocity of the stream, its turbidity, turbulance and other factors must be considered.

Mr. Langdon Pearse states that the Illinois River on one test absorbed 205,000 lbs. of oxygen from the air while flowing a distance of 65 miles, which fact merely shows that oxygen for self-purification can and does come from the air, but this figure cannot be considered for general application, since it represents a certain set of conditions which may or

may not be duplicated elsewhere.

Ohio River pollution studies by the United States Public Health service show that the time of flow from Pittsburgh to the Mississippi River may be anything from 14 days to 129 days, depending on the river stages, which fact again emphasizes the point that each instance of pollution is a problem in itself.

This is only an outline of some of the features of the stream pollution problem, but serves to show that streams have a definite capacity for biological disposal of sewage and trade waste and that if the municipalities, and other sewage or trade waste contributors along the stream, control the amount of pollution which they contribute, by properly designed and operated sewage disposal plants, the streams can be kept in good condition, not only as regards nuisance but as regards water supply, fish life and other features.

The solution of this problem is obvious and calls for

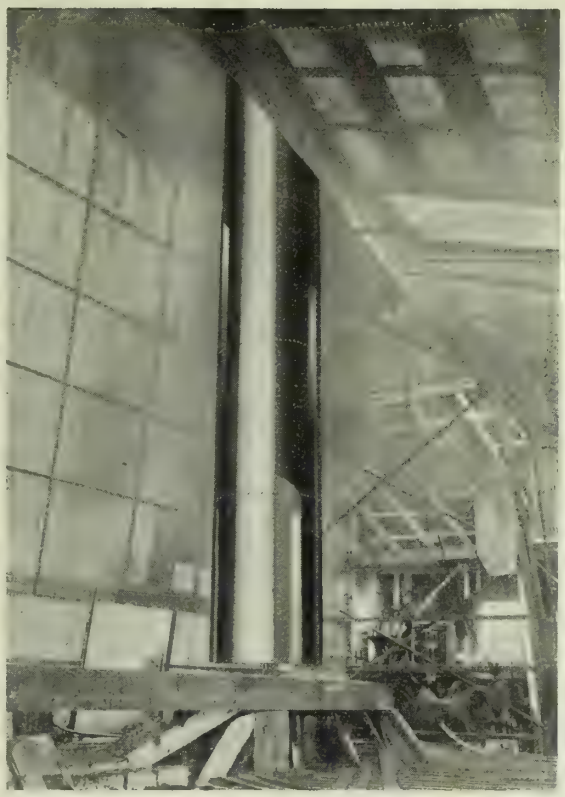
1. Treatment of sewage and trade wastes at their source, to an extent to be determined in each individual case.
2. Maintenance and careful operation of sewage systems and disposal plants.
3. Purification of water at intakes of water supplies, to the extent necessary for safety.
4. Careful operation of water purification plants.

This requires the determination of the extent of purification needed at both ends of the line and for this information we must rely upon information gotten by the Government and State Health Authorities, which are doing immensely valuable work along this line, and deserve better support from the public than they have received in the past.

Customer's Deposit on Disputed Bill Protects Service

The California Railroad Commission has found that the Susanville Water Company, operating in the town of Susanville, Lassen county, was in error in disconnecting the service to J. C. Brokaw, a consumer, to enforce payment of a disputed bill for service, when the latter had made a deposit of funds with the Railroad Commission pending the adjustment of the disputed bill. The Commission directed the utility to revise its charges to Brokaw, and ordered another consumer, who was sharing service on the same line, to pay one-half the disputed bill.

The Commission, in its decision in this proceedings, which, although involving but a small amount, was made the basis for a formal proceeding, re-emphasized the principle that utilities must not discontinue service to enforce collections where consumers have deposited the amount of the disputed bill with the Railroad Commission for adjudication.



Vertical Pipe Dipping Plant of Western Pipe & Steel Co., San Francisco.

Showing application of Biturine Pipe Dip to 60" Water Pipe.

No chain is stronger than its weakest link. No pipe is better than its weakest spot.

To prevent weak spots in pipe lines have them dipped in

Biturine Pipe Dip

"The enemy of corrosion"

Provides a smooth flowing, continuous inside and outside coating; perfect insulation against corrosion from rust, electrolysis, soil acids or alkalis. Will not run in hot weather nor crack at low temperature.

WHO'S *WHO* AND WHO'S *WHERE*

IN THE WORLD OF HYDRAULICS

Personal Notes and Impersonal Observations About Men You Know

Oro McDermith, engineer of the Kittitas Reclamation district, has returned to his office from Washington, D. C., where he represented his district in congressional and departmental hearings.

Eugene P. Hyatt of Lakeside, California, has been appointed by the governor of the state to succeed Dr. L. R. Knorr, resigned, as a member of the board of directors of the recently organized Lakeside Irrigation District.

John Morrow, member of Congress from New Mexico, has been named a member of the House Committee on Irrigation and Reclamation. The appointment is regarded as a matter of congratulation to Mr. Morrow on account of the great and growing importance of irrigation and reclamation in his state.

A. T. Straton, soil expert of the U. S. Reclamation Bureau, is in Yakima, Washington, conducting a soil survey of the Yakima-Benton division of the Yakima reclamation project, working with the co-operation of J. L. Lytel, project manager. The Moxee and Kennewick divisions are to be surveyed as soon as the present work is completed.

William J. Carr, Los Angeles attorney who has been prominent in the debate of the Colorado River problem, has gone to Washington to lend his assistance in possible changes that may be made in the terms of the Boulder Canyon (Swing Johnson) Bill. He will act as a representative of the interests of the city of Pasadena and the city of Glendale.

City officials and engineers of San Diego, California, recently made an inspection tour of alternative sites proposed for the first unit of the city's contemplated water supply improvements. City Manager Fred Rhodes, accompanied by Thornton Mills, hydraulic engineer for the water department, J. W. Williams, consulting engineer, Shelly J. Higgins, city attorney, and Councilman Virgil Bruschi, inspected the proposed route for a pipe-line from Lake Hodges to the city by way of San Pasqual, and the alternative routes via Sutherland and San Vicente.

Dr. Elwood Mead, National Commissioner of Reclamation, is expected to attend the meeting to be held June 24-26 at Yakima, Washington, when the Washington state chamber of commerce will be in session for three days. The meeting is expected to give a good deal of attention to reclamation problems, notably that of state aid, and Dr. Mead will be asked to give a statement of the position of the Reclamation Bureau in the matter.

Pima County, Arizona, has evidenced its interest in water conservation by the appointment of a representative committee to conduct an investigation of the flood waters and other water resources of the county. The chairman of the committee is Fred Ronstadt, who will have the co-operation of C. B. Brown, county agent, in the water studies. The committee was named at a mass meeting of Pima County farmers.

Governor Richardson of California has appointed W. H. West as a director of the La Mesa, Lemon Grove and Spring Valley irrigation district, to succeed J. H. Halley, on the recommendation of the directors of the district. Mr. Halley has been acting as head of the Lemon Grove Mutual Water Company, which is one of the properties to be taken over by the district in its expansion program. When the consolidation contemplated becomes effective Mr. Halley expects to enter the employ of the district to continue his work.

Walker R. Young, construction engineer of the U. S. Bureau of Reclamation, has been named to have charge of the construction of the Kittitas high line canal, the Washington project which will involve an estimated cost of $7,500,000. Mr. Young has had a varied experience with the Bureau, having been connected with important construction work in various parts of the west. His present assignment is to investigations on the Sacramento River in California. It is understood that R. W. Williams, who has been in charge of the Ellensburg office of the Yakima project, will be Mr. Young's assistant.

The policy of the state government of Washington toward reclamation and irrigation was discussed with members of the state reclamation board during March by Mark Moulton, state representative from Kennewick, and F. A. Kern, secretary of the Kittitas reclamation district and newly elected president of the Washington Irrigation Institute. Thirty members of the state legislature and several national congressmen attended the meeting and heard the irrigation men advocate a thorough investigation of all the facts, in order that the next legislature might decide what the state's attitude should be toward continuing the policy of state participation in reclamation.

A delegation of prominent state officials and business men of Idaho were guests of Los Angeles late in March, coming as an official Chamber of Commerce mission in the interest of trade expansion and business co-operation between the northwest and the southwest. The delegation was headed by Governor C. C. Moore, and numbered among its members several well known reclamationists, including Warren G. Swendsen, state Commissioner of Reclamation, and R. E. Shepard, of Jerome, president of the Idaho State Chamber of Commerce.

The personnel of the delegation, in addition to Governor Moore, was: W. G. Swendson, Commissioner of Reclamation; A. H. Connor, Attorney-General; Q. R. B. Kjosness, Commissioner of Agriculture; R. E. Shepherd, president of the State Chamber of Commerce; E. W. Porter, Commissioner of Finance; R. E. Thomas, State Game Warden; J. A. Harader, secretary of the State Chamber of Commerce; O. O. Haga, president of the Boise Chamber of Commerce; J. L. Priest, general agent, Union Pacific Railway system of Boise; F. F. Johnson, president Boise City National Bank; C. J. Sinsel, Boise fruit dealer; J. C. Palumbo; fruit dealer at Pyatt; R. E. Beach, Lewiston merchant; J. C. Jacobsen, C. J. Carlson and L. Wilder, potato growers, Idaho Falls; C. E. Arney, Union Pacific Railway.

Mokelumne River Project Is Making Good Progress

The great Mokelumne River project, eventually to cost $39,000,000, and to supply communities on the eastern side of San Francisco bay with water from the high Sierras transported across the San Joaquin Valley, is making rapid progress toward completion, according to a report rendered by Arthur P. Davis, chief engineer and general manager of the East Bay Municipal Utility District, to the board of directors of that organization during March.

Mr. Davis reported on the various phases of the work as follows:

"Smith Brothers, Inc., contractors for the Lafayette tunnel, have excavated 233 feet of tunnel during the past week, making a total to date of 4278 feet, which is 28.2 per cent of the entire length. A total of 144 feet of invert was poured in the tunnel heading from the west portal. The excavation of the tunnel has been carried on in four of the six headings during the past week and the organization has been enlarged to permit of prosecuting the work at five headings from now on.

"T. E. Connolly, contractor for the Walnut Creek tunnel, has excavated during the past week 72 feet of tunnel, making a total of 2109 feet excavated, or 99.4 per cent of the whole. The tunnel is being trimmed up to shape and concreting will soon start.

"Twohy Brothers Company has erected fifty piers for supporting steel pipe, fifteen are under construction, in a total of 186 piers required. Six sections of pipe have been finished and hauled to the trench and laying of the pipe was begun March 11.

"The testing of plates at Eastern mills and shops has been continued, and at the close of March 12 reports on this work showed that 7006 plates had passed inspection at the mills; 5380 had passed inspection at the shops; 3838 had been shipped from Newport News to Oakland and had been delivered to the Steel Tank and Pipe Company's plant. At the Berkeley shops of the plates received 275 had been rolled and from these 124 pipe sections had been tack welded; 103 had been machine welded; 36 had been tested; 19 had been dipped; 9 had been wrapped and 6 had been sent to the field for installation.

"The water stored in the reservoirs of the East Bay Water Company on March 12 was 5,332,600,000 gallons. The production from the wells during January and February, 1925, was 1,086,800,000 gallons, and for the same months of 1926 was 660,333,000, showing a decreased production from the wells during January and February of 426,500,000 gallons."

DIGGING—CLEANING CANALS

AT LOW COST

THE NEW RUTH WITH ITS CONTINUOUS FLOW OF DIRT will dig or clean canals and trenches at a minimum cost per cubic yard or lineal foot heretofore considered impossible. The Ruth cuts continuous, even banks and smooth bottoms. Working successfully in marshy or dry ground, or canals full of water. The Ruth positively cleans the canal of all muck, sand, small willows, tules and water grasses.

Send for Bulletin No. 8—it illustrates the New Ruth Dredger; type and size of canals it will dig or clean; gives specifications, operating costs and maximum capacities.

RECLAMATION

"WON'T WORK, MR. WORK," SAYS SENATOR McNARY

SENATOR CHARLES L. McNARY, of Oregon, has declined to accept a proposal advanced by Secretary of the Interior Hubert Work, providing for a joint committee to work out a scheme of future construction of new reclamation projects.

Secretary Work, in suggesting the plan to the senator, submitted that some scheme seemed to be necessary to keep expenditures of reclamation funds within safe limits during the next ten years.

Senator McNary based his disapproval of the suggestion on the ground that he did not deem the course of action wise because it would divide responsibility and would result in decentralizing authority in the selection of new projects when centralization of authority is needed to meet the excessive demands on the Reclamation fund. The Senator's letter in full follows:

"Before me I have your recent letter stating that the demands upon the reclamation fund for the construction of new projects far exceed the sum that will be available for a considerable period of time and suggesting that I 'communicate with the Senate and House and request that a special joint committee be appointed, consisting of the Chairmen of the Senate and House Committees on Irrigation and Reclamation, the Chairmen of the Committees on Appropriations of the Senate and House, the Director of the Bureau of the Budget, and the Secretary of the Interior, to work out a scheme of future construction for the purpose of keeping within safe limits the amount of expenditures for the next ten years.'

"You ask me to take this action in the event it appears to be judicious. I regret, Mr. Secretary, to advise you that I do not believe this course of action wise. It would simply divide responsibility now wholly residing in you into as many human units as six is divisible by one, thereby passing the ultimate responsibility around in a circle without a beginning or an end. I feel that such a plan would work for decentralization when centralization of authority is greatly needed to meet the excessive demands on the reclamation fund, particularly when the only reservoir of information of the worthiness of the proposed projects is found in your department, the Bureau of Reclamation, and your chosen soil experts, engineers and economists.

"The laws provide that you may examine into the merits of projects pressing for development and if convinced of their feasibility, transmit your approval with estimates of costs to the Director of the Bureau of Budget, who, if satisfied the costs do not conflict with the economy program, will submit the estimates to the President. Meeting with the President's approval, the estimates are transmitted to Congress for appropriate action.

"The procedure here briefly sketched affords sufficient safeguards against wasting any portion of the Reclamation fund on infeasible projects.

"The present plan and practice of committing to the Secretary of the Interior the responsibility of initiating the consideration of new projects and their construction, in my judgment, should not be substituted by your proposal, however hopeful you may be as to its excellence and desirability.

"In disapproving of your proposal, I must not be understood as being desirous of retreating from any responsibility placed upon me as Chairman of the Senate Committee on Irrigation and Reclamation, as in such a capacity at all times you may be assured of my anxiety to cooperate with you in carrying out successfully this great work of development through reclamation."

SECRETARY WORK'S proposal followed the revelation that the present and immediate demands for reclamation construction are far in excess of any anticipated revenues, making a careful selection necessary among the projects being urged for approval.

Citing that old projects will require $60,000,000 to complete and new projects now pending before Congress will require $60,000,000 more or less, to build, while 15 additional projects have been urged on the Interior Department this winter costing about $40,000,000, the Secretary stated this program of expenditure was considerably in excess of the probable income of the Reclamation fund.

"The average annual receipts of the Reclamation fund applied to construction," he continued, "for the past five years have been approximately $8,500,000. There is no prospect of the annual income being increased during the coming five years. Excluding moneys advanced by private interests to aid in the construction of the American Falls Reservoir in Idaho, the total for last year fell $2,500,000 below the previous year."

The Secretary pointed out that with this threatened diminution in the annual revenues every increase in the number of projects will mean reduction in the amount allotted to each individual project and that there is also the danger, unless a definite authoritative building program is soon adopted, that the funds will be distributed over so many localities that work will be prolonged, costs increased and dissatisfaction engendered regarding delayed development in the localities to be benefited.

In part, his letter read:

"During the present Congress little or no consideration has been given to this financial situation. The Bureau is being continually urged to recommend projects not included in the tentative program. The result is the total of these recommended new projects, which have been introduced in Congress, and for which estimates have been made, aggregates about $33,000,000. If others for which there are no estimates are included, the total will be somewhere between $35,000,000 and $40,000,000. A number of these projects have great merit and should be included in a construction program if there were sufficient funds. With a threatened diminution in the annual revenues, every increase in the number of projects means reducing the amount allotted to an individual one. And there is also danger, if a definite and authoritative program is not soon adopted, that the funds will be distributed over so many localities that the work will be greatly prolonged, its cost increased and dissatisfaction engendered regarding slowness of develop-

Crippled

There is only one right way to turn a dragline

THE Northwest shovel, crane or dragline has two good feet all the time. Even while turning, full power is delivered to both crawlers and it never has to act like a lame duck on the turns.

The Northwest patented crawler base is different. Instead of turning one side into dead iron by shutting it off, the operator slows it down allowing the machine to make an easy turn with full power and minus stress and strain.

Ask any owner what he thinks of Northwest mobility.

Drainage and Flood Control Engineering
By G. W. PICKELS
Assistant Professor of Drainage Engineering, University of Illinois

THIS BOOK COVERS ALL PHASES OF THE DRAINAGE ENGINEER'S WORK FROM THE DRAINAGE OF SMALL AREAS OF FARM LAND BY TILE UNDERDRAINS TO THE RECLAMATION OF LARGE AREAS BY FLOOD PROTECTION, BY DRAINAGE THROUGH OPEN DITCHES AND BY PUMPING.

450 pages, 6x9, Illustrated. $4.00 Net

The marked advance in drainage practice in recent years is emphasized throughout. The sciences of hydrology, hydraulics and soil physics—particularly the results of recent researches—are satisfactorily covered from the specialized viewpoint of the drainage and flood-control engineer.

The book gives a comprehensive and well-balanced picture of drainage practice as carried on today. The economic justification of drainage and flood-control projects is set forth clearly. The legal organization of drainage districts, the essentials of drainage law, and the spreading of assessments make up a final valuable chapter.

ment in the localities which are to be benefited.

"There is a widespread belief that the selection of new projects is largely governed by personal considerations. It needs to be made clear that this is not true. In addition, there is much to be gained by a co-ordinated and carefully thought out program of development, the preparation of which would be participated in by Congress, this Department and the Bureau of the Budget. Such a program, when adopted, should be adhered to until changed by Congressional authority."

PROPOSED new projects and divisions of old projects that are now being asked for number 25 and are located in ten Western States. Oregon leads the list asking for 6 new projects, their total estimated cost amounting to $26,800,000. Wyoming is second with 2 new projects at an estimated cost of $16,060,000 while Washington is third asking for 2 new projects and an extension of an old project, their total estimated cost being $13,800,000. Fourth on the list is Idaho asking for 3 new projects at an estimated cost of $12,430,000.

A list of the States with the number of Federal irrigation projects asked for and their total estimated costs includes: California, three new projects costing $9,771,060; Utah, extension of one old project costing $11,000,000; Nevada, extension of one old project costing $6,291,000; Montana, one new project and extension of one old project at total cost of $4,900,000; Texas, one new project costing $3,000,000; and New Mexico, one new project costing $2,237,000. In addition, three new projects are being asked for in Montana, New Mexico, and Texas for which no estimates of cost have been made.

A list of the new reclamation projects and divisions of old projects asked for with their estimated costs follows:

Project	Estimated Cost
California	
Butte Creek	$ 5,368,880
Deep Creek	3,151,180

President Designates April 18-24 American Forest Week

President Calvin Coolidge has issued a proclamation designating April 18 to 24 as American Forest Week, during which the attention of the nation shall be centered on some of the vital problems of forest conservation and renewal. Canada has joined with the United States in the designation of this week for the purpose, and organizations of both countries interested in forest problems are making special efforts to arouse public interest.

In the United States the Forest Service, the Biological Survey and the Bureau of Plant Industry, as national agencies, will co-operate with state organizations in the observance of the week.

The president, in proclaiming the special week for observance, said:

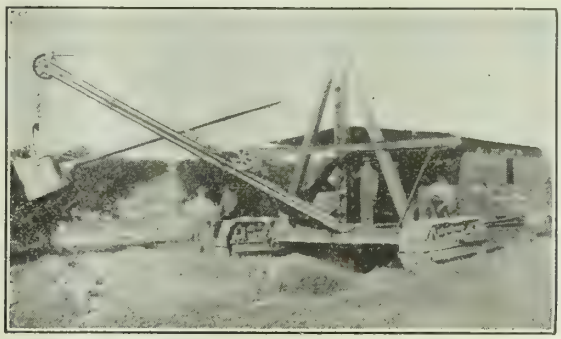
"Although our national progress in forestry has been well begun, much remains to be done through both concerted and individual effort. We must stamp out the forest fires which still annually sweep many wooded areas, destroying timber the Nation can ill afford to lose and killing young growth needed to constitute the forests of the future. Forest fires, caused largely by human indifference or carelessness, are the greatest single obstacle to reforestation and effective forest management.

"We must encourage and extend methods of timber cutting which perpetuate the forest while harvesting its products. We must plant trees in abundance on idle land where they can profitably be grown. We must examine taxation practices that may form economic barriers to timber culture. We must encourage the extension of forest ownership on the part of municipalities, counties, States, and the Federal Government. And we must take common counsel in public meetings to the end that the forestry problems of each region may be well considered and adequately met."

For Cleanout -- Maintenance -- New Ditches

There's a Bay City for Every Job

BAY CITY Land Dredges span the ditch, can dig any desired slope, and dump waste on both banks. BAY CITIES leave clean, wide berms, and can work up or down streams. One trip over the ditch is enough. The Shovel Type Dipper handles hard material in which other types of buckets cannot make a good showing.



At left—One yard BAY CITY Dredge digging and cleaning ditches in Florida Citrus Groves.

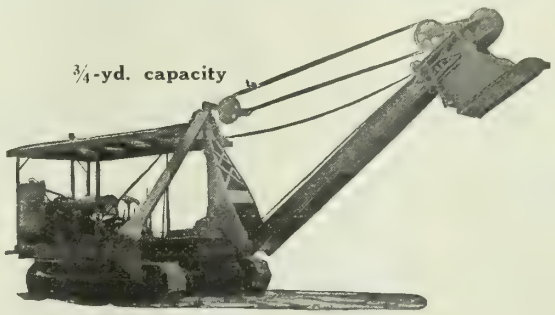
BAY CITY Land Dipper Dredges are built to fit the job. Walking, Crawler, Track or Floating mounting. Easily dismantled, transported and assembled. Capacities ½ to 1½ cubic yards. Oil engine or electric operation.

FOR SMALLER DITCHES — OR PIPE LINE TRENCHES

The BAY CITY 16-B convertible Excavator will handle a wide range of work. Operates Dragline, Trench Shovel, Clamshell or Skimmer. All steel. Shipped assembled. Digs any width or depth up to 20 feet.

STEEL CONSTRUCTION

¾-yd. capacity



FULL CRAWLER MOUNTING

or—Model 4 Excavator

BAY CITY Model 4 is a small low-priced convertible, one-man operated Excavator. Fills the gap between hand labor and high priced equipment. Capacity 20 to 40 cubic yards per hour. Gasoline or electric power. A Real Digger economically designed for the small job. Also operates shovel, and clamshell.

LEGAL *and* JUDICIAL

BY HANKINS & HANKINS

Bond Issue Not a Mortgage

The bond issue of an irrigation district is not a mortgage.

In the case of Kollock v. Barnard, 242 Pac. 847, (Jan. 22, 1926), the Supreme Court of Oregon held that the proper remedy of the bond holders of an irrigation district, to enforce the payment of their bonds, was by the way of a writ of mandamus directed to the directors of the district, requiring the levy of the annual assessment. That another remedy providing for the taking of possession of the irrigation works upon default, under the Oregon laws, was merely cumulative.

The bond issue of an irrigation district is not a mortgage. There is nothing in the statute which gives the bond holder a lien upon the irrigable land included within the district. The primary and only source of the payment of bonds is the annual assessments levied and assessed by the board of directors, and unless the holders of bonds can, by mandamus or otherwise, compel such annual levy, they are without an adequate remedy.

The defendants raised the point that there were sufficient delinquent assessments already levied, which, if collected, would pay the amount due on the books. On this point the court stated: "As we understand the statute, instead of delinquent assessments being available as an asset at the time of making the annual assessment, it is necessary to make provision for such delinquencies in computing the amount to be raised."

May a District Employ Legislative Agents?

Is an irrigation district entitled to employ legislative agents?

A case of great importance to irrigation districts of California has arisen in the Superior Court of Imperial County in an action entitled Crawford vs. Imperial Irrigation District, et al.

In its work of getting favorable action by Congress on the Boulder Canyon Project (Swing-Johnson Bill), the district employed B. F. Fly to appear before Congress and the various Congressional committees to present the case of the Irrigation District. A suit was filed by a land owner to prevent the payment of compensation to Fly.

The case was submitted to the Superior Court on the stipulated facts.

No question of improper means of influencing legislation was involved but the Superior Court considered that an irrigation district had no legal right or authority to expend its money for such purposes, although such purpose was laudable and necessary, and gave judgment against the district.

The irrigation district has taken an appeal to the Supreme Court and the decision of this tribunal should be rendered within the next six months.

The Irrigation Districts Association of California have decided to file a brief as "Amicus Curiae" so as to present the views of all irrigation districts of the state as to their right to expend money for similar purposes.

Liability of Trustees for Negligence

Liability of Levee District trustees for negligence at issue in California case.

In the case of Moore v. Burton, 242 Pac. 902, (.....Cal. App.....) a demurrer was sustained to a complaint alleging damages for negligence on the part of the trustees of the Palo Verde levee district in failing to repair a broken levee. Plaintiff refuses to amend and judgment is given in favor of the trustees.

On appeal the court held that it fairly appearing from the allegations of the complaint that by the acts described and alleged to have been negligent, a dangerous condition was created; that neither the danger nor the injury complained of could have been avoided by the exercise of ordinary care by appellant; and that by no act or omission on his part was the damage caused or contributed to, the complaint was sufficient.

The requirement of the statute that it must appear that the injury was sustained "while the public work or property was being carefully used" was not applicable, as it appeared that the levee work described, unlike roads or bridges, was not of a character permitting its use by appellant.

Judges' Eligibility to Try District Cases

Supreme Court rules on disqualification of superior judges to try irrigation district cases.

An interpretation of the effect of the amendment to Section 170 of the Code of Civil Procedure of California in 1925 by the elimination of paragraph 5 is given by the Supreme Court of California in the case of Hall v. Superior Court of Imperial County, Imperial Irrigation District, et al., Vol———, Page———, California Decision (March 31, 1926). This decision reversed the judgment of the District Court of Appeals in the same case (46 Cal. App. Dec. 908).

The question arose over the right of certain judges owning lands in the Imperial Irrigation District to hear a case involving damages and injunction against the district. A writ of prohibition is asked based both on Sudvision 1 and 5 of Section 170 C. C. P.

The Court points out that Subdivision 5, which disqualified a judge residing in an irrigation district, irrespective of interests, from hearing a proceeding involving such district, was repealed (1925) subsequent to the commencement of the proceedings but that although previously disqualified such judges are not now so disqualified and could proceed to hear the case were it not for Subdivision 1 of the section.

The Court states "The interest which disqualifies a judge from acting judicially in an action under Section 170, Subdivision 1 of the Code of Civil Procedure, must be a certain, definable, pecuniary or proprietary interest which will be directly affected by the judgment rendered . . . and a judge is disqualified if he is a stockholder in a corporation where the corporation is interested in the property involved in the controversy, although not a formal party to the action. . . . The interest of said judges as land owners within said District was such a direct, proprietary interest as to disqualify them from acting in an action involving the property of said District."

A further ruling is made upon respondent's objection to the form of pro-

*Hankins & Hankins are well known attorneys of San Francisco, California, and are attorneys for the Glenn-Colusa Irrigation District.

ceeding, wherein respondent insists that the property procedure is by appeal and not by prohibition. To this point the Court replies: "Where a judge is disqualified to act in any proceeding, or cause, the disability necessarily enters into all orders and decisions made by him other than those specially excepted and provided for in the Codes and to refuse the writ on the ground that a remedy might be had in another manner, would be to permit the trial to proceed to a final conclusion by the disqualified judge and then set aside the proceedings as void ab initio. No good purpose could be served in permitting a disqualified judge to perform certain acts and thereafter declare them void on the ground that he had no jurisdiction to perform the same.

U. S. Not Bound by State Laws

The United States, in operating a reclamation project under the Reclamation Act, is not required to follow state laws.

In the case of Mower v. Bond, 8 Fed. Rep. (2d series) 518 (U. S. Dist. Court, Idaho), the District Manager in the Boise Reclamation Project gave notice to a land owner who had become delinquent in a drainage assessment, that unless payments were made further delivery of water would be withheld. The assessment not being paid the water was shut off.

The Courts have definitely held the levy of assessments (for drainage) to be for "maintenance" and valid.

Plaintiff's principal contention was that in operating the canal system the government and its agents were subject to the laws of the state, and that under such laws, as construed by the Supreme Court of the State, owners of irrigation works are without authority to refuse delivery of water to users because of their failure to discharge delinquencies. This seems to have become the settled rule of the state.

The Federal Court holds that Congress has the power to fix the terms and conditions under which it will sell or permit the use of water on the project and is not bound to follow the decisions or rulings of the state Courts.

Prescription Includes Rights Necessary to Use

A ditch right of way acquired by prescription includes rights necessary for the use of such ditch.

In the case of Neville v. Loudon Irrigation Canal & Reservoir Co., 242 Pac. Rep. 1002 (Colo. Jan. 18, 1926) the Supreme Court reviews the title of a plaintiff in an irrigation ditch which had been acquired by use for some thirty years. The appellants claim that, since the title was by prescription, the right must be limited in scope and extent to what was actually used.

The Court states: The basic ques-

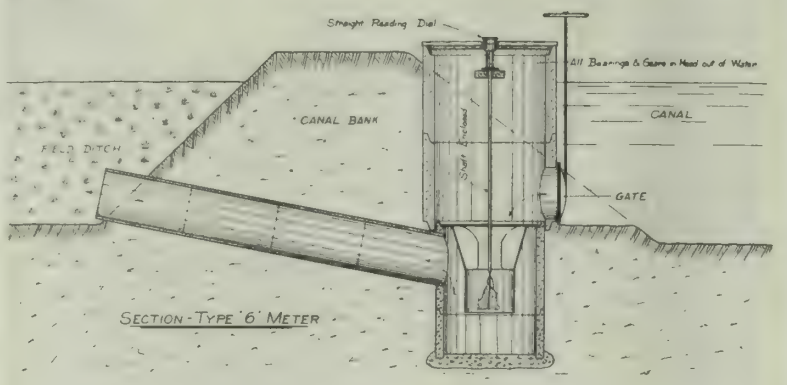
The RELIANCE METER



THE "Type 6" Reliance Irrigation Meter offers you standardized permanent construction at a very low first cost. Their sustained efficiency with a minimum of upkeep has been proven by 12 years usage. Cut shows installation of the 4 sec. ft. size in 24 and 30-inch concrete pipe. This is the standard type of setting adopted by many irrigation districts in Texas and elsewhere who are now equipping all their deliveries with this device. The "Type 6" meter is furnished in sizes ranging from ½ up to 16 sec. ft.

tion, of course, is, What rights were acquired by prescription? The answer is, "All that is reasonably necessary to the convenient and proper use and maintenance of the ditch." The right of way for a ditch includes the right to maintain it, and that includes repairs, ingress and egress with space therefor as exigency may show.

New Engineering Organization Formed in San Francisco

A group of San Francisco engineers have formed a new engineering society, known as the Society of Engineers. Five hundred members, formerly affiliated with a well known national engineering organization, decided on the move last December when a reapportionment of the funds of the older organization was made by which national headquarters would receive more than local chapters.

The new Society includes representatives of the civil, architectural, mining, mechanical and electrical branches of the engineering profession. Its objects are non-technical in character and devoted to co-operation and the social interests of its members. The officers are: C. H. Tucker, president; Glen B. Ashcroft, vice-president; Albert J. Capron, Secretary. The board of directors consists of W. H. Phelps, C. T. Wiskocil, R. C. Briggs, L. W. Hunt and Louis L. Leury. George E. Tonney is in charge of Public Affairs.

Irrigation Moves Forward in Old Spain

Spain is the latest country to join in the quest for improved water power and hydroelectric development by the nations of both hemispheres. King Alfonso inaugurated the new Spanish irrigation work in Andalusia a few weeks ago by laying the foundation of a great dam near Andujar, where the Jandula empties into the Guadalquivir, the only river in Spain which flows freely at all seasons.

This dam will be 295 feet high and 720 feet long and its estimated cost is $5,000,000, half to be borne by a private company and half by the State. It is expected to furnish 26,000 horse-power of electrical energy as well as to irrigate a large tract of land much needed in that section for cultivation, as indeed is the case almost everywhere in Spain except in Leon and the provinces bordering on the Bay of Biscay. The site of the works is in the wild Sierra Morena, which separates the plateau region of Castile and Estremadura from the Andalusian plain and forms the watershed between the upper Guadiana and the Guadalquivir.

MODERN Irrigation

Are *You, Too,* Profiting From the Onward March of Reclamation?

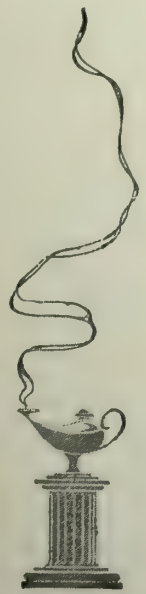
AS RECENTLY announced in these columns, the Republic of Mexico, following the lead of the United States, has passed a "Reclamation Bill" and will expend $30,000,000.00 on some twenty irrigation projects.

The Grecian government, also, taking its cue from the success of such enterprises in America, India, Egypt, Australia and elsewhere, has determined upon a comprehensive program of reclamation and irrigation in Macedonia and will spend approximately $34,000,000.00 on this work.

It is a noteworthy fact that American engineering firms have been placed in charge of both of these undertakings.

Since America (the United States) leads in the manufacture of the most modern irrigation appliances, and auxiliary equipment of every description, the major percentage of these millions will in all probability (aside from labor costs) be spent within the boundaries of the United States.

American-made drag-lines, dredges, and other excavating machinery; trucks, tractors and automobiles; cement, cement re-inforcing and other materials; pipe and pipe fittings; gates and valves; motors and motor controls; meters and other odds and ends that go to make up a fully equipped irrigation project—these will have to be provided for, and the United States is the logical source of supply.



The advertising columns of MODERN IRRIGATION are the logical source of current information regarding such equipment. Engineers and other executives, who do ordering or specifying, will find these columns during 1926 a reliable "Who's Who" of manufacturers selling the hydraulic field. Here the leading, most progressive concerns in every line will be represented.

At this moment, the pages of MODERN IRRIGATION are being examined, and examined carefully, by men whose yearly purchases in *your* line aggregate large sums of money. Long-pull advertising will help you to secure a larger percentage of this annual turnover. The men who buy are reading and studying these advertisements—never doubt it. Consciously, or unconsciously, they are forming their opinions and narrowing down their ultimate choice of equipment. Many actual decisions are made months in advance of the order for the goods.

These projects are but two of the countless many under contemplation—or actual construction—at this time. Nineteen-twenty-six will be a big year in the irrigation and allied hydraulic industries. Millions will be spent for replacements and other millions for new equipment. Are YOU making your proper bid for a share of this business? Are you represented, as an advertiser, in the columns of MODERN IRRIGATION?

If not, phone, wire or write immediately for rates and complete information. Just say: "We wish to sell more equipment this year to the hydraulic field. How can MODERN IRRIGATION help us do it? Rush full particulars."

OVERHEAD IRRIGATION

OVERHEAD SPRINKLING HOLDS SPOTLIGHT OF INTEREST

THE increase in acreage under overhead sprinklers throughout the citrus and avocado districts of California during the last twelve months has been several hundred per cent, says Marvin B. Rounds, farm advisor of Los Angeles County in the CITROGRAPH. He goes on to predict that the increase during the next twelve months will, no doubt, be fully as great, judging by the large number of growers who are taking an interest in the subject with a view toward installing overhead irrigation equipment in their orchards. Many are only waiting until it has thoroughly proven itself, as manifested by the success of the systems in those orchards already installed.

Quoting further from Mr. Round's article:

The overhead method is one which has been tried on small plots and in small orchards in several districts of California during the last ten or fifteen years, but it was not until about 1924 that the empetus came, and the acreage under overhead irrigation began to increase very rapidly. Most of the earlier installations were portable or semi-portable; that is, the standards on which the heads were placed were moved about the orchard much like the method practiced in lawn sprinkling, differing, however, in that the standards were of such a height that the sprinklers were above the trees.

MR. ROUNDS describes an interesting installation, that of A. M. Stephens, citrus grower, north of La Verne, who has an overhead irrigating system which has been installed on about 65 acres. This installation has been worked out according to the best known engineering methods and is an example of the necessity of considering the individual orchard or ranch in preparing for this method of irrigation. Mr. Stephens' ranch has a variation in elevation of about 400 feet, the upper end of his planting being actually 380 feet higher than the lower end. The proper distribution of water through a system in an orchard of this kind, allowing for a uniform pressure throughout, is a problem for an engineer. On this property, the matter of pressure and distribution of water has been worked out and tested in such a way that the owner feels he will obtain as uniform distribution as it is possible to obtain under present conditions.

Mr. Stephens has three reservoirs on the property from which he obtains his pressure, one of 200,000 gallons, one of 1,500,000 gallons, and one of 1,250,000 gallons capacity. Center lines, composed of eight-inch pipe, are the leaders, and have five-inch laterals. Each lateral has a shut-off, and each riser for the sprinkler heads also has a shut-off valve. In this way the pressure can be regulated throughout the orchard. Each head receives a pressure of 30 pounds. The compound type of head is used, which is composed of two long arms, on one of which is mounted another whirling spray with shorter arms. As the long arm revolves slowly, the short arm whirling spray, mounted on one of the larger arms, whirls very swiftly as compared to the large arm. This is one type of sprinkler head which is being used in many orchards.

TWO general types of sprinklers are in use: the overhead pipe with openings for the water, and the one attached to an upright which may spray the water on a circular area. The latter type may be divided into revolving heads, and heads which spray the water on a circular area without revolving. Revolving heads may have long arms and supply water to an area covering several trees, or they may be a type having short arms which whirl swiftly and cover one tree. The compound type of sprinkler, already referred to, is perhaps in a class by itself, belonging to the long-arm type. All revolving types of heads obviously cover a circular area and it would be expected that a decrease in the size of the area, with an increase in the number of heads, would increase efficiency in distribution. Just how far one can go in this respect remains to be seen after growers have had experience with the installations already in. Certain it is that this feature of overhead equipment is an important consideration.

Another important consideration is pressure, which, of course, is related to topography of the land, source of water, size of pipes, and in fact to all of the engineering phases of installation of overhead equipment. It is necessary that the system operate a given number of sprinklers so that a sufficient amount of water is delivered in a given time. Individual control of sprinkler heads is necessary in order properly to regulate each one.

It is usually necessary to provide for removal of a part of the riser and the sprinkler head at times, especially when the orchard is fumigated.

Growers have taken an interest in the overhead method for various reasons. Some have thought that labor expense could be reduced; also that water for irrigation could be more economically used. Many have known that they were not getting a proper distribution of water in their orchards through the old furrow method, and others have thought that certain insects and diseases might be controlled by means of this method. Whatever the reasons, we recognize the fact that there are many advantages possible under this system.

Although we do not have the data available for proof, it would be natural to expect to obtain (1) a better distribution of water; (2) a more economical use of water, through a better distribution; (3) probably a greater degree of efficiency in the use of fertilizers applied; (4) a more ideal condition of the entire root feeding zone, making for greater availability of the plant food elements within the soil; (5) the carrying of surface nitrates down to the root feeding zone of the soil; (6) the saving of labor; (7) a small amount of water for use every few days during the fall, promoting a better stand of covercrop plants. We may also find that it is especially adapted to steep hillside farming, and that there will be a reduction in the cost of cultivation. It is hoped that it will be possible to prevent some of the so-called June drop by increasing the humidity during a period of very dry weather.

Whether all of these advantages will

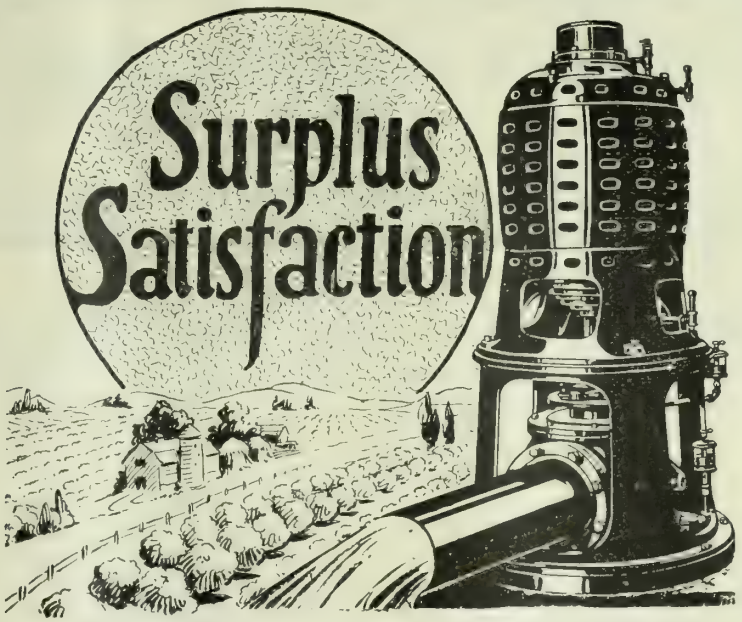
be realized or not remains to be seen. It should be thoroughly understood, however, that we do not have sufficient data at the present time to make any absolutely positive statements. It appears reasonable to expect that through the proper regulation of soil misture, some of them will be effected. Neither have we any information to indicate that insect control will be accomplished. Most of the orchards which have been installed with the overhead system up to the present time, especially those which have been under observation for from three to six years, are in a light type of soil. Orchards in a heavy type of soil, in which the overhead method of irrigation has been used, have not been under observation for a sufficient length of time to draw any conclusions as to the possible effect on the tree so far as certain trunk and root diseases are concerned. Under a light type of soil, we would not expect to run into any difficulties as far these diseases are concerned, but it is well known that in heavy types of soil, where water stands around the trunk of the tree, certain of these fungus trunk and root diseases become apparent.

The cost of installing overhead irrigation equipment cannot be accurately stated because of the varying conditions. In general, however, one can say that the cost is approximately $300 per acre, especially where a booster pump does not have to be installed. If a booster pump does have to be installed, this will naturally run the expense up higher. By using reconditioned pipe, a saving of $25 an acre may be realized. Should a grower care to try the method out in an orchard, without going to the expense of permanent equipment, the portable or semi-portable installation may be used, and the cost cut down very materially.

Drainage Pays the Farmer

(*Continued from Page 15*)

what he can accomplish by the use of small open ditches, random tile drainage and terraces. These improvements are such that they will increase the yield of his farm with scarcely any outlay except of his own time and labor. There are two ways of increasing income; one is to cut down the cost of operation, the other to increase the production without increasing cost of operation. Better drainage will increase production and cut down cost of operation. I know of no better type of improvement at the present time than those that I have described. This is the kind of drainage that pays dividends from the start, and if carefully planned should prove profitable to any farmer who has wet or eroding land that needs improvement.



Thoroughly dependable--made for rugged service--performing faultlessly on every job

PEERLESS LOS ANGELES PUMPS

meet the demand for better irrigation at less cost. Municipal water plants have found Peerless Pumps completely reliable for heavy duty and small ranchers know the worth of the smaller types.

Made for wells 7 inch or larger—capacity 180-3000 gallons per minute. Write us your problem. We will show you real co-operation.

SURVEY *of* HYDRAULIC DEVELOPMENT

As Shown by Official Records of the Month -- Local, State, and Governmental

Applications Filed

Among the applications for permit to appropriate water filed with the State Department of Public Works, Division of Water Rights, (California) during the month of March were the following:

Application No 4936 (San Diego County) —Gustar Ahlzen, c/o C. E. Burch, 205 Security Bank Bldg., San Diego, Calif., for .075 cubic foot per second from unnamed spring and Show Canyon. To be diverted in Section 5, T 12 S, R 4 E, and Sec. 6, T 12 S, R 4 E, S.B.M. for domestic and irrigation on 5 acres. Estimated cost $5,000.

Application No. 4937 (Riverside County)— F. D. R. Moote, 517 H. W. Hellman Bldg., Los Angeles, Calif., for .12 cubic foot per second from N. Fork San Jacinto River tributary to San Jacinto River. To be diverted in Section 24, T 4 S, R 2 E, for irrigation and domestic purposes on 100 acres. Estimated cost $5,000.

Application No. 4940 (Glenn County)— Glenn-Colusa Irrigation Dist., c/o F. H. Tibbitts, Alaska Commercial Bldg., San Francisco, Calif., for 3000 cubic feet per second from Sacramento River tributary to Suisun Bay. To be diverted in Section 2, T 22 N, R 2 W, M.D.M. for power purposes in Sec. 5, Glenn Ranch Survey, 12,955 H.P. to be developed. Estimated cost $2,000,000.

Application No. 4941 (Marin County)— Leo M. Harvey and Louis Evans, c/o Gouge, Robinson & Hughes, 622-627 C. C. Chapman Bldg., Los Angeles, Calif., for 2 cubic feet per second from Olema Creek and Bear Valley Creek tributary to Tomales Bay. To be diverted in Section 12, T 2 N, R 9 W, and Section 17, T 2 N, R 8 W, M.D.M. for irrigation and domestic purposes on 640 acres. Estimated cost $30,000.

Application No. 4942 (Contra Costa County) Rindge Land Reclamation Dist., No. 2036, P. O. Box 785, Stockton, Calif., for 30.8 cubic feet per second from Old River, Rock Slough, India Slough tributary to San Joaquin River. Movable diversion in Sections 1, 11 and 12, T 1 N, R 3 E, and Sec. 36, T 2 N, R 3 E and Secs. 5, 6, 7, and 8 T 1 N, R 4 E, and Sec. 31, T 2 N, R 4 E, M.D.M. for irrigation purposes on 2464.6 acres in Palm Tract.

Application No. 4943 (San Joaquin County)—Rindge Land Reclamation Dist., No. 2037, P. O. Box 785, Stockton, Calif., for 85.45 cubic feet per second from San Joaquin River Disappointment, 21 mile and 14 mile sloughs tributary to San Joaquin River. Movable diversion in Sections 1 and 12, T 2 N, R 4 E, and Secs. 5 to 11 inc., 13 to 18 inc., 20 to 24 inc., 26 to 29 inc., T 2 N, R 5 E, M.D.M. for irrigation purposes on 6836 acres in Rindge Tract.

Application No. 4944 (San Joaquin County)—Rindge Land Reclamation Dist., No. 2038, P. O. Box 785, Stockton, Calif., for 71.74 cubic feet per second from Empire Cut, Whiskey Slough and Middle River tributary to San Joaquin River. Movable diversion in Sections 1, 2, 3, 10, 11, 12, 13, 14, 15 and 16, T 1 N, R 4 E, and Secs. 5, 6, 7, 8, 9, 16, 17, and 18, T 1 N, R 5 E, M.D.M. for irrigation purposes on 5,739 acres on Lower Jones Tract.

Application No. 4945 (San Joaquin County—Rindge Land Reclamation Dist., No. 2039, P. O. Box 785, Stockton, Calif., for 78.6 cubic feet per second from Trappers Slough, and Middle River tributary to San Joaquin River. Movable diversion in Sections 13 to 16 inc., 21 to 27 inc., 35 and 36, T 1 N, R 4 E, and Secs. 16 to 21 inc. and 29 and 30, T 1 N, R 5 E, M.D.M. for irrigation purposes on 6288.6 acres on Upper Jones Tract.

Application No. 4951 (Butte County)— Herbert W. Barman, P. O Box 85, Chico, Calif., for 10 cubic feet per second from Canal of Drainage Dist. No. 100, tributary to Sacramento River. To be diverted in Sections 30 and 31, T 19 N, R 2 E, M.D.M. for irrigation purposes on 700 acres of rice in Secs. 25 and 26, T 19 N, R 1 E, and Secs. 30 and 31, T 19 N, R 2 E, M.D.M. Estimated cost $1000.

Application No. 4953 (San Diego County)—Frank A. Hansom, Escondido, Calif., for .075 cubic foot per second underground water tributary to Escondido River. To be diverted in Section 16, T 12 S, R 2 W, S.B.M. for irrigation and domestic purposes on 4 acres. Estimated cost $1200.

Application No. 4956 (Butte County)— Mrs. Kate Haack, 1201 Robinson Street, Oroville, Calif., for 3.2 cubic feet per second from Lateral E. I. No. 833 Drainage Ditch tributary to Sacramento River via Butte Creek. To be diverted in Section 6, T 17 N, R 2 E, M.D.M. for irrigation purposes on 128 acres of rice in Sec. 6, T 17 N, R 2 E, M.D.M.

Application No. 4957 (Riverside County) —Herman Luhrman, Palm Springs, Calif., for .12 cubic foot per second from E. Fork Stubby Creek tributary to Whitewater River. To be diverted in Section 36, T 2 S, R 2 E, S.B.M. for irrigation purposes on 10 acres Sec. 36, T 2 S, R 2 E, M.D.M. Estimated cost $800.

Application No. 4958 (Los Angeles County)—The Women's Home Missionary Society of the Methodist Episcopal Church of Southern California Conference, c/o J. A. Allard, 313 First National Bank Bldg., Pomona, Calif., for .29 cubic feet per second waste water tributary to San Dimas Wash. To be diverted in Section 2, T 1 S, R 9 W, S.B.M. for irrigation purposes on 23 acres.

Application No. 4959 (Butte County)— Manly S. Harris, 116 Post St., San Francisco, Calif., for 15 cubic feet per second from Main Canal and Lateral C Drainage Dist. No. 833 tributary to Sacramento River. To be diverted in Sections 3 and 10, T 17 N, R 1 E, M.D.M. for irrigation and stock purposes on 2,510 acres in Secs. 10, 13, 14, 16, 21, 22 and 23. Estimated cost $10,000.

Application No. 4961 (Stanislaus County) —C. C. Crookshank, c/o L. J. Maddux, Modesto, Calif., for 2.54 cubic feet per second from Tuolumne River tributary to San Joaquin River. To be diverted in Section 17, T 4 S, R 8 E, M.D.M. for irrigation purposes on 203 acres in Sec. 17, T 4 S, R 8 E, M.D.M. Estimated cost $3500.

Application No. 4962 (Lassen County)— E. A Julian, 421 Crocker First National Bank Bldg., San Francisco, Calif., for 17,000 acre feet per annum from Long Valley Creek tributary to Honey Lake. To be diverted in Section 10, T 23 N, R 17 E, M.D.M. for irrigation purposes. Estimated cost $216,000.

Application No. 4963 (Butte County)— Edward Schirmer, Gridley, Calif., for 4 cubic feet per second from Lateral E—Reclamation Dist. No. 833 tributary to Sacramento River via Butte Creek. To be diverted in Section 33, T 18 N, R 2 E, M.D.M. for irrigation purposes on 300 acres of rice in Sec. 33, T 18 N, R 2 E, M.D.M. Estimated cost $1000.

Application No. 4964 (San Diego County) —Hugh Hendershot, c/o A. R. Arnold, Escondido, Calif., for .12 cubic feet per second Underground Water tributary to Escondido River. To be diverted in Section 16, T 12 S, R 2 W, S.B.M. for irrigation and domestic purposes on Lot 4, Block 147, Rancho Rincon del Diablo projected Sec. 16, T 12 S, R 2 W, S.B.M. Estimated cost $1200.

Application No. 4965 (San Bernardino County)—J. C. Miller, San Bernardino, Calif., for 0.12 cubic feet per second from spring tributary to Hook Creek. To be diverted in Section 13, T 2 N, R 3 W, for domestic purposes in SW ¼ Sec. 13, T 2 N, R 3 W. Estimated cost $125.

Application No. 4968 (Inyo County)—Roy Journigan, Lone Pine, Calif., for 3.20 cubic feet per second from unnamed stream tributary to Lone Pine Creek. To be diverted in Section 31, T 15 S, R 34 E, M.D.M. for domestic and irrigation.

Application No. 4970 (Kern County)—E. B. Hilborn, Leliter, Calif., for .37 cubic foot per second from Short Canyon (7 springs) tributary to Inyokern Valley. To be diverted in Section 31, T 25 S, R 38 E, M.D.M. for agriculture and domestic purposes on 40 acres in Sec. 31, T 26 S, R 38 E. Estimated cost $3500.

Application No. 4971 (Humboldt County) —City of Eureka, Eureka, Calif., for 4400 acre feet per annum from Jacoby Creek tributary to Humboldt Bay. To be diverted in Section 30, T 5 N, R 2 E, H.M. for municipal and domestic in City of Eureka. Estimated cost $500,000.

Application No. 4975 (Ventura County)— Guy T. Stetson, Henry S. Nixon, Trustees, proposed Ojai Irrigation District, c/o J. B. Lippincott, 543 Petroleum Security Bldg., Los Angeles, Calif., for 30,800 acre feet per annum from Sespe Creek tributary to Santa Clara River. To be diverted in Section 6,

IRRIGATION PIPE

Tell us if you have trouble--

If it's with Montague Steel products we'd like the privilege of correcting any faults. If it's with other makes we'd like to show you why your first investment in Montague Steel Products is practically your last.

75 years experience is yours to command. Write for any of these special FREE booklets:

Montague Well Casing.....5-A
Riveted Steel Pipe.....5-B
Surface Irrigation Pipe.....5-C

We also make a full line of Oil and Water Tanks—Siphons—Stacks and Steel Flumes—and a genuine safety water tube boiler, 1 to 20 h. p., and up. Prices upon application.

MONTAGUE PIPE & STEEL CO
San Francisco California

More than just a stopping place; a central point from which you enjoy most thoroughly all San Francisco's attractions—the beautiful Plaza overlooking Union Square.

Post St. at Stockton
SAN FRANCISCO

T 5 N, R 22 W, S.B.M. for power purposes in Sec. 31, T 5 N, R 22 W, S.B.M. 6818 H.P. to be developed. Estimated cost $2,060,000.

Application No 4977 (Santa Barbara County)—J. G. Reinhart, c/o Preisker, Preisker & Goble, Bank of Santa Maria Bldg., Santa Maria, Calif., for 0.73 cubic foot per second underground water tributary to Los Alamos Creek. To be diverted in Section 21, T 8 N, R 33 W, S.B.M. for irrigation purposes on 58.43 acres in Sec. 21, T 8 N, R 33 W, S.B.M. Estimated cost $2500.

Application No. 4978 (Contra Costa County)—Sleepy Hollow Syndicate, 1622 Harrison St., Oakland, Calif., for 80 acre feet per annum from unnamed stream tributary to San Pablo Creek. To be diverted in Sections 27 and 28, T 1 N, R 3 W, M.D.M. for domestic and irrigation purposes on 190 acres,—Golf Links and parks.

Application No. 4979 (San Joaquin County—Ira E. Saunders, c/o Ohm & Raab, 517 E. Market St., Stockton, Calif., for 0.96 cubic feet per second from Middle River tributary to San Joaquin River. To be diverted in Section 1, T 1 S, R 5 E, M.D.M. for irrigation purposes in Secs. 1 and 12, T 1 S, R 5 E, M.D.M. Estimated cost $2000.

Application No. 4980 (Lassen County)—Red Rock Creek Irrigation Dist., c/o Secretary, Red Rock, Lassen, Calif., for 16,500 acre feet per annum from Red Rock Creek tributary to Madeline Plains. To be diverted in Sections 5 and 10, T 35 N, R 16 E, and Section 22, T 36 N, R 16 E, M.D.M. for irrigation purposes on 10,260 acres. Estimated cost $76,800.

Application No. 4981 (Lassen County)—Red Rock Creek Irrigation Dist., c/o Secretary, Red Rock, Lassen Co., Calif., for 8,100 acre feet per annum from Cold Springs Creek tributary to Madeline Plains. To be diverted in Section 25, T 36 N, R 15 E, M.D.M. for irrigation purposes on 10,260 acres. Estimated cost $26,800.

Application No. 4982 (Los Angeles County)—Ralph Bennett, 1125 Central Bldg., Los Angeles, Calif., for 15,000 acre feet per annum from Big Rock and Pallett Creeks tributary to Antelope Valley. To be diverted in Section 6, T 4 N, R 9 W, S.B.M. for irrigation purposes on 5000 acres in T 4 & 5 N, R 9 & 10 E, S.B.M.

Application No. 4983 (Trinity County)—Lewiston Dredging Co., 725 Standard Oil Bldg., San Francisco, Calif., for .01 cubic foot per second from Big Roycroft Gulch tributary to Trinity River. To be diverted in Section 21, T 34 N, R 8 W, M.D.M. for irrigation and domestic purposes on 6 acres in Sec. 22, T 34 N, R 8 W, M.D.M. Estimated cost $1000.

Permits Issued

Among the more important permits to appropriate water issued by the Department of Public Works, Division of Water Rights of California, during the month of March, 1926, were the following:

Permit No. 2447, Application No. 4663 (Butte County)—Issued to E. L. Adams, Chico, Calif., March 19, 1926 for 22.5 cubic feet per second from Hamlin Slough in Section 8, T 20 N, R 2 E for irrigation of 1214.9 acres near point of diversion. Estimated cost $400.

Permit No. 2448, Application No. 4664 (Butte County)—Issued to Gorrill and Hotchkiss, Chico, Calif., March 19, 1926 for 22.5 cubic feet per second from Hamlin Slough in Section 17, T 20 N, R 2 E, for irrigation of 2338.3 of rice near point of diversion. Estimated cost $250.

Permit No. 2449, Application No. 4665 (Butte County)—Issued to Gorrill and Hotchkiss, Chico, Calif., March 19, 1926 for 15 cubic feet per second from Butte Creek in Section 7, T 20 N, R 2 E, for irrigation of 2338.3 acres near point of diversion. Estimated cost $1500.

Permit No. 2450, Application No. 4821 (Sacramento County)—Issued to Chas. A. Driver, Roseville, Calif., for 0.44 cubic feet per second from Dry Creek in Section 14, T 10 N, R 5 E, for irrigation of 35 acres in Sec. 14. Estimated cost $1000.

Permit No. 2451, Application No. 4836 (San Bernardino County)—Issued to Pozzo Construction Co., Los Angeles, Calif., March 31, 1926 for 0.1 cubic foot per second from Tunnels in Brodek Canyon in Section 18, T 1 N, R 6 W, for domestic and irrigation of 80 acres in Sec. 25, T 1 N, R 7 W.

OREGON

Among the more important applications for permit to appropriate water filed in the office of Rhea Luper, state engineer of Oregon, during March were the following:

B. G. Macy of Sparta, covering the appropriation of water from Saw Mill Gulch for irrigation of 10 acres in Baker County.

Lewis G. Haven of Portland, covering the appropriation of water from Banning Creek for irrigation of 40 acres in Josephine County, at a cost of $600.

G. H. Smith of Santa Ana, California, covering the appropriation of water from Board Shanty Creek for irrigation of 12 acres in Josephine County.

Lenn J. Smith of Crescent, covering the appropriation of water from Crescent Creek for irrigation of 58 acres in Klamath County, at a cost of $300.

A. H. Shafer of Enterprise, covering the appropriation of water from Hurricane Creek for supplemental irrigation of 15 acres in Wallowa County.

Chester I. Simmers of Crescent, covering the appropriation of water from Crescent Creek for irrigation of 40 acres in Klamath County, at a cost of $300.

M. B. Chapman of Camas Valley, covering the appropriation of water from Coquille River for irrigation of 16 acres at a cost of $500; also, covering the appropriation of water from an unnamed creek for domestic purposes in Douglas County.

J. H. Griffith of Williams, covering the appropriation of water from Cherry Gulch for irrigation of 16 acres in Josephine County, at a cost of $250.

M. J. Lee, Trustee, of Canby, covering the appropriation of water from Molalla River, natural flow, seepage, waste, and stored water, for irrigation and power purposes in Clackamas County.

Mr. Sherman J. Warner of Mt. Vernon, Oregon, covering the appropriation of water from Rann Creek for irrigation of 15 acres, in Grant County.

Mr. John J. Rathkey of Looking Glass, Oregon, covering the appropriation of water from Ten Mile Creek for irrigation of 15 acres, in Douglas County, at a cost of $1,000.

M. A. S. Welch of 126 Lombard St., Portland, Oregon, covering the appropriation of water from an unnamed stream for irrigation of 10 acres, in Clackamas County, at a cost of $200.

For Detailed Listings, Branch Offices, Etc., See the Buyers' Guide to Leading Supply Sources—Pages 55-56

Mr. Clarence M. Bogart of Richland, Oregon, covering the appropriation of water from Squaw Gulch for irrigation of 20 acres, in Baker County, at a cost of $200.

Mr. G. Evert Baker of Northwestern Bank Bldg., Portland, Oregon, covering the appropriation of water from an unnamed stream, tributary of Devil's Lake, for municipal purposes, in Lincoln County.

Mr. J. H. Woodcock of Maupin, Oregon, covering the appropriation of water from Clear and Frog Creeks for the construction of Clear Lake Reservoir for the storage of 20,000 acre feet. Proposed to use the stored water for irrigation and domestic purposes in Wasco County.

City of Eugene, covering the construction of the Bear Creek Reservoir for storage of 30,000 acre feet of water from McKenzie River, and the appropriation of the stored water and water from McKenzie River, and Johnson Creek for development of 23,863 theoretical horsepower; also the appropriation of 5,200 cubic feet per second of water from The McKenzie River and water stored in the Bear Creek Reservoir for development of 71,363 theoretical horsepower. The proposed development will cost approximately $4,281,780, and is within Lane County.

Johnie G. Warner of Trail, covering the appropriation of water from Wall Creek for irrigation of 15 acres in Jackson County, at a cost of $300.

J. H. Woodcock and L. C. Henneghan of Maupin, covering the appropriation of water from Boulder Creek, Clear Creek and White River for irrigation of approximately 15,000 acres in Wasco County.

Fred R. Young of Pendleton, covering the appropriation of water from Mountain Creek for irrigation of 13 acres in Umatilla County.

Howell Ditch Company of Richland, covering the appropriation of seepage water from Waterbury-Allen Ditch for supplemental irrigation of 418 acres in Baker County, at a cost of $9,000.

Denied Service Extension

The application of the Pismo Beach Water Company, a utility serving a few consumers in a real estate subdivision adjacent to the town of Pismo, for permission to furnish water to the town of Pismo Beach, has been denied by the California Railroad Commission, the Commission having recently authorized a group of responsible citizens of Pismo Beach to take over and operate El Pismo Water Company, formerly operated by W. W. Ward. The new owners of El Pismo Water Company will carry out the program of improvement of the service ordered by the Commission.

Rate To Be 12c per 100 Cu. Ft.

Belvedere Water Corporation, supplying consumers in vicinity of Belvedere Gardens, Los Angeles County, has been authorized by the California Railroad Commission to place in effect a rate of 12 cents per 100 cubic feet for all water delivered to consumers in excess of 5,000 cubic feet per month on and after April 1, 1926, in place of the present rate of six cents.

Would Extend System

Euclid Avenue Water Company, Los Angeles County, has applied to the California Railroad Commission for permission to extend its public utility service to a tract of 10 acres adjoining its present system, and to issue 100 shares of stock for the purpose of financing such extension.

Commission Orders Rate Reductions

The California Railroad Commission, in a decision rendered March 20, ordered adjustments in the rates, rules and regulations of the Sutter-Butte Canal Company, operating in Sutter and Butte Counties, California, which will result in the reduction of rates for rice irrigation in the main territory served, and the elimination of so-called "continuous contracts" which have been a bone of contention between the company and the water users for a number of years.

Under the terms of the decision, the chief reductions of rates for irrigation water for rice growing are: reduction of the rates for gravity flow water in the Butte and Sutter County area, 45 cents per acre per year; reduction of the rate on pumped water, 65 cents per acre per year, and establishment of prepayment discounts on service charges. The pumping rate will be decreased from $10.45 per acre per year to $9.80; gravity water rates will be reduced from $8.95 per acre per year.

Asks Commission Refuse Authority

Moor Park Farmers Water Company of Moor Park, Ventura County, California, has filed a complaint with the California Railroad Commission against A. H. Hitch, requesting the Commission to refuse to authorize the latter to engage in a public utility water business for the purpose of supplying Ventura County Water Works No. 1 or the county of Ventura with water to the detriment of the existing business of complainant.

Seeks New Rate Schedule

Citizens Water Association, which recently took over the property of El Pismo Water Company, Pismo, California, has applied to the Railroad Commission, for authority to establish a schedule of rates producing a fair return upon the property, and permitting of the carrying out of improvement of the system as agreed upon when the system was taken over from its former management.

Sonoma Company to Sell

Permission has been granted by the California Railroad Commission to the Sonoma Water and Irrigation Company to use $10,160 obtained from the sale of its eight per cent cumulative preferred stock to acquire the public utility water system of A. E. Joscelyn, who operates under the fictitious name of Sonoma Vista Water Company.

Wants Permit to Issue Stock

Plymouth Water Company, engaged in the business of selling water for domestic and irrigating purposes at Plymouth, Amador county, California, has applied to the state Railroad Commission for authority to issue 4950 shares of its capital stock to M. C. Randolph.

Would Sell Garden Grove System

Garden Grove City Water Company, engaged in supplying water to the town of Garden Grove, Orange County, California, has applied to the Railroad Commission of the state for permission to sell said system to Orange County Water Works District No. 3.

Time for Sale Extended

An extension of time has been granted by the California Railroad Commission to Conservative Water Company, until December 31, 1926, in which to issue and deliver bonds previously authorized by the Commission.

See the New Straight Drive Pacific Pump

EACH a compact unit, easily accessible, perfectly aligned, with no flexible coupling. "Smooth as Velvet." Motors of 7½ to 50 H.P., interchangeable on the same head. The last word in pump engineering. Write or call.

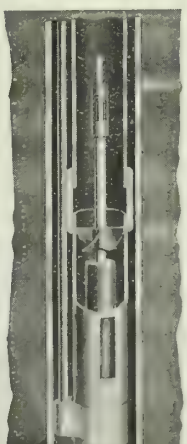
Phone Midland 3101

IT'S THE *BOTTOM OF THE WELL* THAT COUNTS!



A great NEW principle for pumping water has been evolved. The advantages of the air-lift have long been recognized.
The idea of an air-driven turbine *pump*, however, combining every advantage of the ordinary air-lift—with its marked economies of cost and upkeep—is now a practical reality. No more sand troubles—no more expensive repairs and shutdowns. All parts requiring attention or repair are *on the surface*. Cut at left tells the story. Agents wanted in open territory. Send for literature.

AMONG OUR CONTRIBUTORS

Editorial Jottings About Current and Forthcoming Feature Articles, Dealing With Practical Problems of Hydraulics, and the Men Who Have Written Them

GORDON ZANDER, who writes of the adjudication of water rights in California, was born in San Rafael, in that state, was educated in the public schools of Oakland, and was graduated from the University of California in 1913. After having filled minor engineering positions with the Pacific Gas and Electric Company, the Spring Valley Water Company and the California Highway Commission, he entered the employ of the State Water Commission of California in 1917. For the past nine years he has been with the State Water Commission and its successor, the Division of Water Rights, continuously with the exception of a period of about a year and a half during the World War, when he was on active duty in the United States Army. Since 1920 he has served in the capacity of Associate Hydraulic Engineer, in charge of the adjudication and water distribution work of the Division.

DOZIER FINLEY, author of the article on corrosion of underground pipe, was graduated from the University of California in the class of 1902, having specialized in chemical engineering, with particular reference to the oil and asphalt industries. For eleven years subsequent thereto he was chief chemist and in charge of engineering for The Paraffine Paint Company and was in charge of chemical work until the entry of the United States into the world war.

He was a captain in the ordnance department during the war, having charge of the manufacture of certain special explosive and pyrotechnic materials for the ammunition section. Since the war he has been in charge of technical research work for The Paraffine Companies, Inc., and has given particular attention to the problem of protection of underground irrigation, gas, water and oil pipe.

He is a member of The American Chemical Society, The American Society for Testing Materials, The American Gas Association and The Pacific Coast Gas Association.

ORSON WINSO ISRAELSON, who tells what irrigation has done for Utah, is one of the scholarly men whose abilities have been directed toward the service of irrigation through research and education. He was born in Utah and educated there, receiving the Bachelor of Science degree from the Agricultural College of Utah in 1912. In 1913 and 1914 he served with the Division of Irrigation Investigations of the Department of Agriculture, and received his Master's degree from the University of California in 1914. For the following two years he taught as an instructor in experimental irrigation at the University of California, going to the Agricultural College of Utah in 1916, and remaining there until the present time, first as assistant professor of irrigation and drainage, later as associate professor and finally professor and head of the department. In 1925 he was awarded the degree of Doctor of Philosophy from the University of California, having prepared his thesis on "The Application of Hydrodynamics to Irrigation and Drainage Problems." In addition to his educational work he has done consulting work with special reference to problems in duty of water connected with water-right adjudications. He is a member of a committee appointed by the Irrigation Section of the American Society of Civil Engineers to investigate the consumptive use of irrigation water. He is the author of a large number of articles in this field for the technical press and official bulletins.

GORDON ZANDER

S. H. MCCRORY and W. W. MCLAUGHLIN are the men who head the invaluable work that is being done in irrigation and drainage by the Division of Agricultural Engineering of the U. S. Department of Agriculture. Mr. McCrory is chief of the division, and has charge of drainage investigations; Mr. McLaughlin is associate chief, and is at the head of irrigation investigations. Both of these men have been in the government service for many years and are recognized for their knowledge of the field and their considerable contributions to its technique and literature. Mr. McLaughlin's article is a continuation of the "An Outline of Irrigation" which appeared in the March issue, in which he traced the development of irrigation and of his division during the past thirty years. Mr. McCrory's article is a republication of a paper which he delivered before a recent middle-west convention.

C. H. PEASE, writing on "Two Rivers of Doubt," has already been introduced to the readers of MODERN IRRIGATION. His article is the second part of "The Riddle of the Rio Grande," published in the last issue. W. H. SNELSON is senior irrigation specialist of the Dominion Irrigation and Reclamation Service, stationed at Calgary, Alberta, Canada. His article on the water requirements of winter wheat is a presentation of the results of eight years of experimenting on this subject by himself and associates. HUGH CRANE is a regular staff contributor.

NATHAN T. VEATCH, JR., author of the article entitled "Stream Pollution is a National Problem," is a consulting engineer in private practice in Kansas City, Missouri, a member of the firm Black & Veatch. He was educated in the middle west, and obtained his earliest experience in railroad work with the Santa Fe. In 1909 he was in charge of the design of a sewage system and sewage disposal plant for the city of Holton, Kansas, following this experience with drainage survey work. Later in 1909 he served as resident engineer for Worley & Black, consulting engineers, on two municipal water and light plants, and the following year became that firm's principal assistant. He was connected with the American Water Works and Electric company, for a time in their head offices at Pittsburgh, Pennsylvania, but for the most part of the connection serving as superintendent of the City Water Company at Keokuk, Iowa. In 1914 he entered private practice under the firm name of Black and Veatch and has been successfully practicing since that time. He has perfected many special features in connection with water and sewage purification plants, such as chemical feeding apparatus and control apparatus. A large number of civic and technical organizations number him as a member, and he has contributed many articles to the technical press.

PAUL BAILEY, deputy chief of the Division of Engineering and Irrigation of the California Department of Public Works, is a man with a mission. He is in charge of the investigation of one of the most audacious and stupendous irrigation projects ever conceived, which, among other features, would turn the San Joaquin River around and make it flow from the ocean toward its source. He will describe this project and the investigations which are being made, in the May issue of MODERN IRRIGATION.

HYDE FORBES, consulting hydraulic engineer, is interested, as a great many readers of MODERN IRRIGATION are, in the relative merits of general and special engineering studies for students planning on entering some phase of irrigation or water development work. He places the problem before you for discussion in the May issue.

GEORGE SWENDSEN is one of the well-known engineer-managers of the west. He is chief engineer and general manager of the Fresno (Calif.) Irrigation district. His address before the recent meeting of the California Irrigation Districts Association on "Irrigation District Management." It will be published in the May issue of MODERN IRRIGATION.

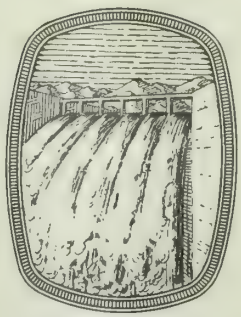
PETROLEUM WORLD 626 S. SPRING ST., LOS ANGELES, CALIF. MODERN IRRIGATION

HUBERT WORK

Secretary of the Interior, whose speech in Los Angeles in April on the subject of the Colorado River and its development was the chief sensation of the month, and who was in the southwest, accompanied by Elwood Mead, Commissioner of Reclamation, studying various aspects of the proposed Boulder Canyon project. Dr. Work has committed himself to having some definite proposal to submit to Congress when it convenes next December.

MODERN Irrigation
The Magazine of Applied Hydraulics



Volume II MAY, 1926 Number 5

The Progress *of* Irrigation

SPEAKING to an audience which he addressed as "the representative people of California," Hubert Work, Secretary of the Interior, on April 26 made a commitment on the subject of the Colorado River that is regarded by many observers as equally significant to that recorded a few days earlier, when the Senate Committee on Irrigation and Reclamation reported the Swing-Johnson bill favorably by a vote of 12 to 3.

Secretary Work appeared in Los Angeles as the guest of two civic organizations, accompanied by Dr. Elwood Mead, his Commissioner of Reclamation and his chief dependence in matters affecting this aspect of the Department's work. His address was heard by 850 persons. Twice his audience interrupted to applaud his statements, once when he asserted that "for the first time concrete, specific recommendations, comprehending the diversified and co-ordinated use of the river were made to Congress by the present administration of the Interior Department," and again when he declared: "If there are those among you who for personal, partisan or political advantage are embarrassing this project, they should be excluded from our councils."

TWO OTHER statements in his address were of special importance. After tracing the legislative history of the Boulder Canyon project, and broadly intimating that the early adjournment of Congress might find definite action still lacking, in spite of the senate committee's favorable report, he said:

"Should Congress fail to instruct the Secretary of the Interior to secure contracts for the sale of power and water from the Colorado River, to potential consumers, he proposes to initiate such procedure himself and, if possible, have formulated something tangible to present to Congress when it meets next winter."

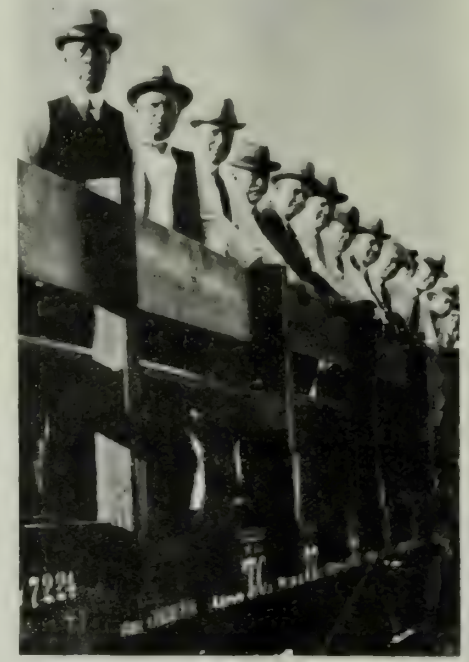
In concluding his remarks, during the course of which he had argued that the complex interests and diverse considerations involved in the development of the Colorado make it properly and necessarily a field for government activity, the Secretary asserted:

"If an organized corporation, competent and willing to develop this project in its several ramifications, will come forward and submit a contract to build these structures and place their operation under such control of the Government as will protect the many and diversified interests involved, the Secretary of

the Interior will recommend to Congress that such proposition be sympathetically entertained."

This statement was variously interpreted by listeners. Some considered it to be a suggestion that the project should be no longer delayed, and that, if federal action could not soon be decided upon, the way should be cleared for private exploitation. Others saw in it a hint that the City of Los Angeles, regarded as an "organized corporation," might be considered as a proper agency for undertaking the project, the government failing to assume the responsibility; while another element chose to accept it as a challenge to private corporations to advance plans which would insure the safeguarding of all interests under a plan of private development. Secretary Work was quoted, in the press, as explaining this statement as such an invitation to the power corporations to come forward with an adequate plan for private work under government control.

The greater part of the Secretary's address is given in another part of this issue.



SENATE IRRIGATION COMMITTEE IN MEXICO

This picture was taken when the senate committee was in the southwest last fall, investigating the Colorado River situation, and shows the shirt-sleeved solons on the crest of the Pescadero Dam, 26 miles below the Mexican border.

THE favorable report of the senate committee on irrigation was the second event of the month which earlier indicated progress in the direction of federal action on the Colorado River controversy and gave encouragement to those favoring the plan outlined in the Swing-Johnson bill. After a group of amendments presented by the upper basin states had been added to the measure, it came to a vote by the committee on April 23 and was favorably reported by a vote of twelve to three, the opposition consisting of Arizona's two members, Senators Ashurst and Cameron, and Senator Phipps of Colorado. These three have been counted as the foes of the measure.

The senators who voted in favor of the measure in committee were: McNary of Oregon, committee chairman; Kendrick, Wyoming; Jones, Washington; Shortridge, California; Johnson, California; Sheppard, Texas; Walsh, Montana; Pittman, Nevada; Simmons, North Carolina; Dill, Washington; Gooding, Idaho and Oddie, Nevada.

Some partisans have been encouraged by this action to believe that the passage of the bill is a possibility before Congress adjourns, and the legislative fathers of the measure have announced that they will push it to conclusion if possible in the month or so remaining in this session, concentrating their efforts before the House Committee on Irrigation and Reclamation. The indications are, however, that final action will not be obtained, and that the summer recess will intervene before the fate of the measure will be known.

REPORTS from various sections of the irrigation country have a prevalent tenor of optimism as the 1926 irrigation season opens. Ample rainfall has assured a plentiful supply of water in most parts of the west, has relieved the long continued dry period in Northern and Southern California, and from Arizona comes word that 424,484 acre-feet of water stand in the Roosevelt Reservoir.

New irrigation districts are being organized in almost all of the irrigated states, large construction programs are being conceived and launched by the more flourishing districts, and western municipalities are responding to their increasing population by advanced and ambitious programs for the development of domestic supplies.

Congress, before it adjourns, will probably approve a federal reclamation program somewhere midway between extreme conservatism and undue optimism, which, as a compromise between the "defeatists" and the pork-barrel, will perhaps be as wise a course as it is possible to obtain. The final appropriations will care for large works now in preparation, will grant much-needed relief to some harassed districts, and will make funds available for some new projects.

Fundamentals of District *Management*

Irrigation Districts Represent "Big Business"; Must Be Directed on Principles that Control Other Great Business] Enterprises

Says
GEORGE L. SWENDSEN
Chief Engineer and General Manager, Fresno Irrigation District.

TOP
Concrete Check Dam in Main Canal of the Fresno Irrigation District.

CENTER
Diversion Gates on the District's Main Fresno Canal.

LOWER
A Lined Section of the Main Canal. These Pictures Prove that Irrigation is Not Without its Aesthetic Appeal.

IRRIGATION DISTRICTS are organizations of big business. In California alone there are eighty-six active irrigation districts organized and functioning under the state irrigation district act. The aggregate area of these districts is given as 3,434,992 acres and the aggregate of authorized bond issues as $120,020,831.

Seventy-two of these district organizations, comprising 2,210,000 acres, approximately two-thirds of the whole area, have been brought about within the last ten years. From reliable sources we are informed that, of the bond issues authorized, approximately $75,000,000 have been sold and presumably the funds thus secured, together with funds otherwise provided, are invested in the irrigation systems of the various districts.

To carry on the work of annual maintainance, operation and improvements to the canal systems, to pay interest on bonds and to provide funds for retiring bonds as they become due requires assessments on the lands within these districts involving an aggregate amount of probably $10,000,000 annually. These facts alone justify the statement which introduces this article. But when we consider that these institutions have vested in them water rights and franchises many times more valuable than the investment in works and facilities we must certainly conclude that such institutions are of necessity of very great importance in our economic welfare.

When we further consider that irrigation is a paramount necessity to agricultural production in the vast area within the confines of these districts we are reminded that these irrigation agencies are, in reality, the very foundation of our agricultural activities.

It will doubtless be profitable and of some interest to consider some phases pertaining to the conduct of the business belonging to these enterprises of big business, especially as related to the operation and maintainance problems. Much interest always attaches to construction features, especially on new projects, but these are usually peculiar to individual projects, while there are many problems of operation and maintainance common to all districts.

Our law vests the control of district affairs in the hands of an elective board of directors with broad powers and duties. As a matter of fact, there is probably no public institution wherein the responsible officers are given more latitude in the conduct of affairs than is provided by the California Irrigation District Act. It is certain that the limits of the law cannot be charged with any failure in the conduct of the business of these institutions. The directors are not expected to, and usually do not function in handling the details of the districts business, but are obliged to delegate this duty to an executive. The major physical problems in district operation involve more or less engineering and thus an executive with engineering experience is usually chosen.

Like that of any other business, the progress of the district is dependent almost entirely upon the initiative of the executive. This is true whether the district be large or small. To meet his responsibilities he must be an executive in reality, should thoroughly inform himself on the fundamentals of district procedure, must necessarily acquaint himself thoroughly, by personal contact, with all major problems requiring first consideration and, with the advice and

counsel of the directors, build up the organization that is necessary to meet the requirements of his district.

Generally speaking, irrigation district activities can be considered under four general heads.

(a) Records, accounts and finances, generally in the hands of the Secretary and Treasurer.
(b) Assessment and collection of taxes which are functions of the elective officers which the law provides for these activities.
(c) Operation, maintenance and improvement of the canal system.
(d) Legal guidance and advice.

As to (a) and (b) they are more or less routine efforts and as to (d) it seems we are unable wholly to dispense with it. However, it is important that the executive understand the activities of these departments very thoroughly. He can effect much co-ordination of effort, resulting in more thorough and effective work. He should at least exact from these departments:

(1) A monthly statement by the Tax Collector showing collections and balances.
(2) A monthly statement from the Treasurer showing receipts and bank balances.
(3) A monthly statement from the Secretary co-ordinating and exhibiting all financial activities of the district for the previous month.

Periodic audits, preferably every month, should be made by a competent auditor, checking all financial matters and particularly reconciling (1), (2) and (3). With these major routine matters in hand, with the knowledge that modern, up-to-date, records of finance and assessments are in use, and with thorough safeguards on all financial transactions and obligations, the executive can confidently approve the routine monthly reports of such departments which should be provided for the board of directors at each of their regular monthly meetings.

Of course (c), operation, maintainance and improvement of the canal system, offers an almost unlimited field for the energetic executive. I shall only attempt to stress a few features which I consider most important.

(1) Fundamentally, the operation of a system depends upon the field

GEORGE L. SWENDSEN

forces. The executive, by as much personal contact as possible, through adequately advised superintendents and by periodic educational meetings of these forces, can do much to direct and co-ordinate the efforts of these men and thus put into effective use the plans he should have matured for these activities.

(2) While operation and improvement of neighborhood lateral ditches is not primarily a burden of the district nevertheless the organization should function in these matters to the extent of such advice and judicious co-operation as to bring about the best possible conditions for equitable service. We have found such activities most helpful and appreciated among our landowners.

(3) One important element of successful management is the full co-operation and confidence of the landowners. To gain this the executive must advance to a position of leadership in all phases of irrigation and water supply matters as related to his district and in all cases assist the community generally in any judicious efforts to advance interest in these matters.

(4) The district directors are generally very glad to have the executive bear the burden of necessary direct contact and relations with the landowners and he cannot function effectively in any other manner. However, it is always helpful and desirable that board members be kept fully informed on such matters and that they act directly with the executive in considering matters where precedents and policies may be established, thereby gaining first hand information to assist in final determinations. The competent and judicious executive will always find much desirable assistance in such procedure.

Manager Must Be Co-ordinator

The directors of a district having given due latitude and support to an executive have a right to exact from him that he fully and effectively co-ordinate the work in all departments and render to them, monthly or otherwise as they may require, comprehensive reports concerning all features of the institution's activities.

District Tax Collectors, Assessors

(*Continued on Page 32*)

TEN PRACTICAL QUESTIONS TO ALL PRACTICAL IRRIGATORS

By O. W. Israelsen, Professor of Irrigation and Drainage, Utah Agricultural College

Do You Know:

(1) That most irrigators apply excessive amounts of water to porous, gravelly bench lands?

(2) That gravelly soils usually retain less than one inch depth of water in one foot of soil and never retain more?

(3) That the depth of gravelly soil which sustains crop growth and therefore needs irrigation seldom exceeds two or three feet?

(4) That an irrigation stream of two cubic feet per second, the average size "irrigating" stream in Utah, will supply in one hour and thirty minutes all the water than one acre of gravelly soil 3 feet in depth can retain?

(5) That all irrigation water in excess of what the soil can retain leaches from the bench lands valuable plant food and water-logs the lower lands?

(6) That to avoid waste, irrigation water must be rushed over gravelly land by applying it to narrow strips and in short runs?

(7) That you cannot rush small streams over gravelly, porous land?

(8) That poorly-leveled gravelly land cannot be uniformly covered with water even by the use of large streams and short runs?

(9) That if you fail to know these facts or to apply them in your irrigation practice, failure of crops through leaching of bench lands and water-logging of low-lands is sure to follow?

(10) That it is far easier to prevent injury and crop failure from soil leaching and water-logging than to correct the injury?

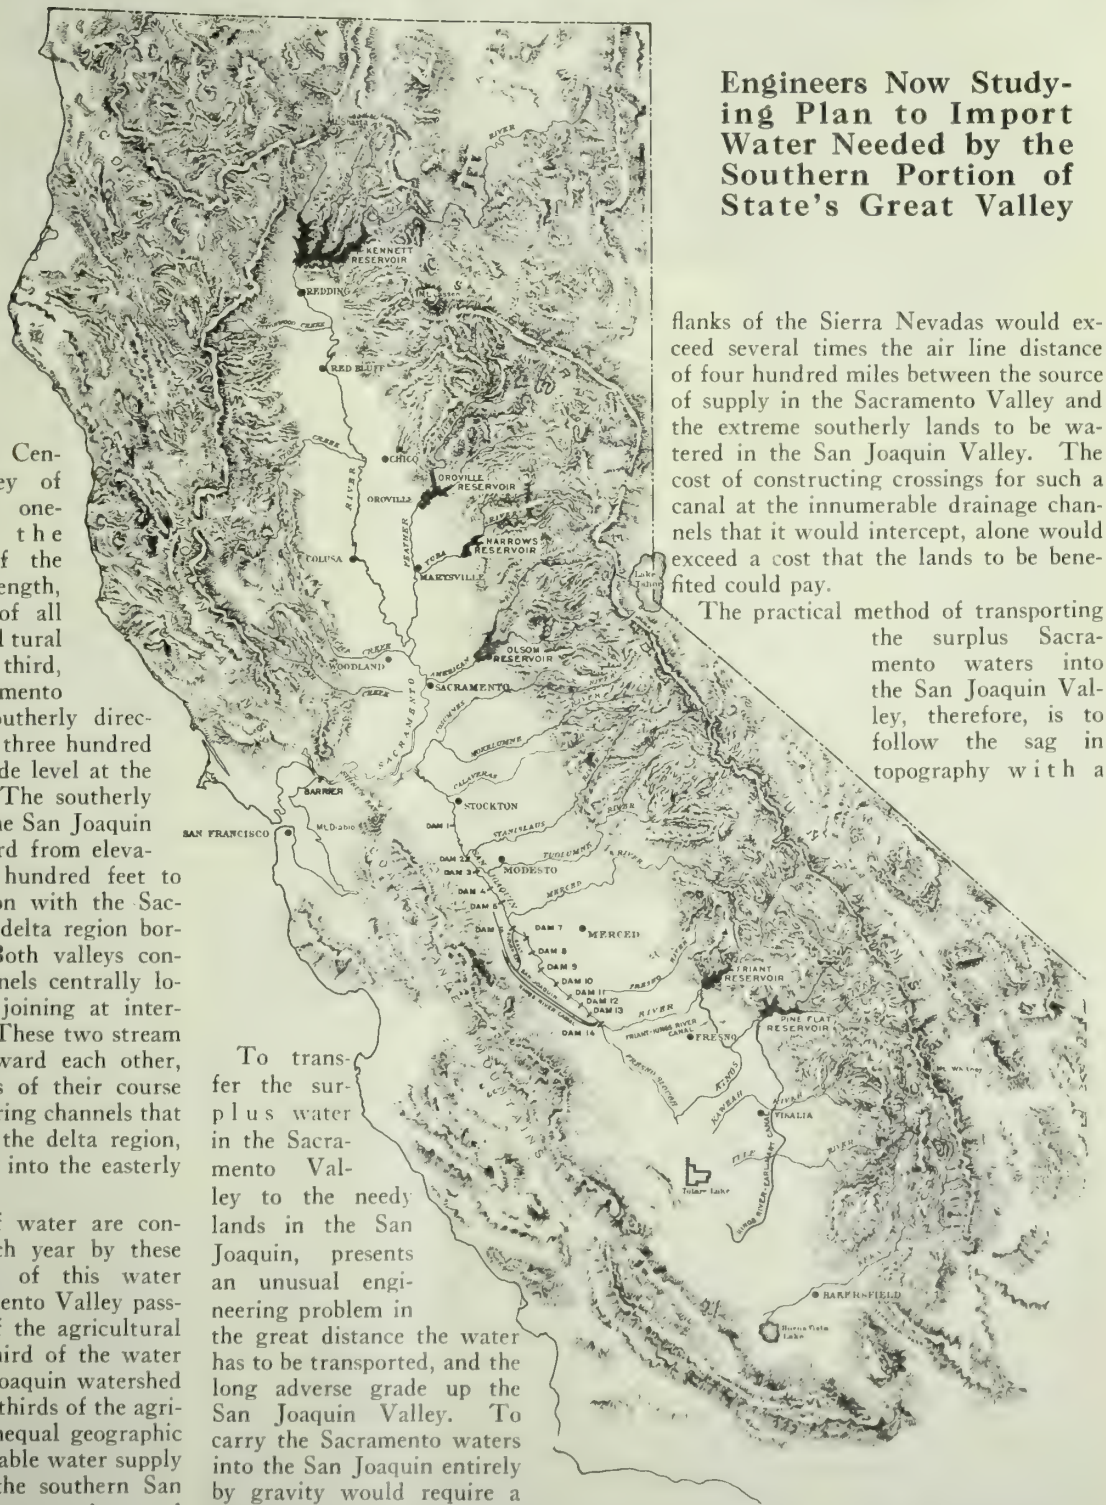
A Plan to Irrigate California by Turning the San Joaquin River Upside Down

By PAUL BAILEY
Deputy State Engineer of California

Engineers Now Studying Plan to Import Water Needed by the Southern Portion of State's Great Valley

THE Great Central Valley of California, one-fourth the breadth of the State and half its length, comprises three-fifths of all California's agricultural lands. The northern third, known as the Sacramento Valley, slopes in a southerly direction from elevations of three hundred feet above the sea to tide level at the head of Suisun Bay. The southerly two-thirds, known as the San Joaquin Valley, slopes northward from elevations of three to five hundred feet to sea-level at the junction with the Sacramento Valley in the delta region bordering Suisun Bay. Both valleys contain main stream channels centrally located with tributaries joining at intervals along their way. These two stream channels in sloping toward each other, meet in the last stages of their course through several meandering channels that separate the islands of the delta region, and then jointly empty into the easterly end of Suisun Bay.

Immense volumes of water are conveyed into the sea each year by these channels. Two-thirds of this water drains from the Sacramento Valley passing by but one-third of the agricultural land, while only one-third of the water originates on the San Joaquin watershed that is tributary to two-thirds of the agricultural land. This unequal geographic distribution of the available water supply causes large areas in the southern San Joaquin Valley to be separated several hundred miles distant from regions of surplus supply in the Sacramento Valley. The intervening topography is smooth enough for easy conduit location but sags greatly in elevation through its middle part.



OUTLINE OF FIRST UNIT OF THE PLAN

This map shows the major features of the plan which is being studied by the California Division of Engineering and Irrigation for the importation of water into the San Joaquin Valley. It is described in more detail in the latter part of the accompanying article, Page 24.

To transfer the surplus water in the Sacramento Valley to the needy lands in the San Joaquin, presents an unusual engineering problem in the great distance the water has to be transported, and the long adverse grade up the San Joaquin Valley. To carry the Sacramento waters into the San Joaquin entirely by gravity would require a long sinuous canal constructed on the steep sides of the Sierra Nevada Mountains. The mountains on the westerly side of the valley lack supporting elevation for such a canal as they approach the head of Suisun Bay. The total length of the sinuous grade line on the flanks of the Sierra Nevadas would exceed several times the air line distance of four hundred miles between the source of supply in the Sacramento Valley and the extreme southerly lands to be watered in the San Joaquin Valley. The cost of constructing crossings for such a canal at the innumerable drainage channels that it would intercept, alone would exceed a cost that the lands to be benefited could pay.

The practical method of transporting the surplus Sacramento waters into the San Joaquin Valley, therefore, is to follow the sag in topography with a

conduit on the smooth valley floor. The low point in this sag is at sea-level at the junction of the two rivers. From this point the water must be raised against the grade of the valley floor for an extreme distance of two hundred and fifty miles.

The engineering advisory committee, in the field, investigating the plans to which Mr. Bailey refers in his article. From left to right, A. J. Cleary, G. A. Elliott, B. A. Etcheverry, A. Kempkey, F. C. Herrman, Paul Bailey, and W. L. Huber. William Mulholland, J. B. Lippincott and Louis Hill are absent members of the committee.

At first glance the problem appears to be insolvable at costs within an economic horizon. The Division of Engineering and Irrigation of the State Department of Public Works has been pursuing a solution to this problem in their Water Resources Investigation that was initiated by the Legislature of 1921. A complete inventory of the waters in all the streams and of the future needs for water, are contained in the Division's first report* to the 1923 Legislature. These studies point out the necessity of irrigation throughout the Great Central Valley and the approaching limit to development in the Southern San Joaquin Valley, unless means are found to overcome the unequal geographic distribution of the natural water supply in the Great Central Valley.

Although much of the land in the Great Central Valley will produce grains and some of it fruits without irrigation, intensive cultivation and diversified cropping require more favorable soil moisture conditions than exist in the natural state. The mean annual rainfall varies from five to twenty-five inches but practically all of this falls during the winter months. The soil moisture can only be maintained in favorable amounts during the long warm summers by artificially adding to the natural supply by irrigation. With irrigation, these lands can be brought to maximum productivity and a great diversity of crops can be grown.

Limit of Resources in Sight

Irrigation has been in progress for many years, especially in the San Joaquin Valley. All the easily developed waters are now in use and less than half of the lands have even an imperfect supply. More water is needed on much of the land already under irrigation in the middle and late summer months during every year, and throughout the season in dry years. Many of the projects in the San Joaquin Valley are now at work formulating construction programs to perfect these supplies. However, the entire mean seasonal run-off of all the San Joaquin Valley streams is only enough to cover its agricultural lands a foot and one-third in depth each season if it all could be conserved. It is estimated that two feet in depth is needed on an average to bring these lands into maximum productivity. This deficiency in supply is greatest in the southern part of the valley that lies at the highest elevations.

Balancing this deficiency in water supply in the southern sections of the Great Central Valley, is a large surplus in the regions to the north. With respect to their needs for water, the mean seasonal run-off of the Sacramento Valley streams is three and one-half times greater than that in the San Joaquin streams and much more than is needed for the full development of the Sacramento Valley. The investigations of the Division of Engineering and Irrigation show that there is ample reservoir capacity on the Sacramento watershed to equalize this streamflow for use in both valleys.

Plans for conveying this surplus of the north to the deficient regions in the south are in the process of formulation and will be the subject of a report by the Division of Engineering and Irrigation to the Legislature of 1927. A report† on a first unit of such a plan was presented to the 1925 Legislature but due to the many complications involved in a scheme of this magnitude, recommendations were withheld until further study could be applied to the problem.

These studies are now in progress under a legislative appropriation for this purpose. They are being directed by the writer in consultation with a committee of eminent consulting engineers who have been called together to advise with the Division of Engineering and Irrigation on this problem.

It is found that the practical method of collecting the surplus waters from the various tributaries of the Sacramento and transporting them through the first half of the distance, is in the channel of the Sacramento River. Although the average grade of the river is about twice that needed for conveying the same water in a canal and there is consequently a loss of head in running the water in the river channel, nevertheless the cost of excavating a new channel far exceeds the value of this loss in head.

The surplus waters of the Sacramento would then arrive at the mouth of the Sacramento River at sea-level and have to be lifted by pumping to the elevations of the San Joaquin Valley lands. Before these waters can reach the pumps that would boost them up the grade of the San Joaquin Valley, they would have to cross through the channels of the island region from the lower Sacramento River into the San Joaquin. The ultimate conception of this plan as first laid out requires a barrier below the mouth of the two rivers to divert this water across the delta region without its escape into the sea, or its mingling with the salt waters of Suisun Bay. Studies of the design and cost of this barrier are now in progress that they may be compared with the cost of similar accomplishment by other methods.

Two Plans Studied

Two plans of conveying this water from the mouth of the San Joaquin River up the adverse grade of the San Joaquin Valley floor have been studied. The first method proposed a grand canal 200 miles long into which water could be pumped at its northerly end. This canal would run southward against the grade of the valley on the westerly side of the main river channel in a location selected for smooth topography and easily obtained rights of way. Eight successive lifts would be required along this route to raise the water through a pumping height of 400 feet. This would permit the transportation of the water to the southerly end of the valley floor. Additional pumping would be required from this main canal to reach all the

Don't Forget that Vital Factor *Ground-Water*

Student Technologists in their Schooling, Practicing Engineers in New Developments, Need Specialized Knowledge on this Specialized Aspect of Hydraulics

PART I

HYDE FORBES

By HYDE FORBES
Engineer and Geologist

MUCH space in engineering publications has recently been devoted to discussions of the relative merits of *general* and *special* engineering study presented by the curricula of our universities. The writer's purpose in presenting this article is to obtain, through discussion, the opinion of engineers practicing in the West as to the necessity or advisability of student engineers and geologists of western institutions preparing themselves in the basic or fundamental principles involved in the study of ground water hydrology.

At the present time there is a striking meagreness of definite data relative to many phases of ground water hydrology, and even an uncertainty as to the real applicability of many oft-quoted and widely accepted principles of ground water occurrence and movement. It appears, therefore, that the student, whose study lays the foundation for, and points the way towards, a better understand of the natural phenomena relating to the water beneath the earth's crust, will be in a position at the outset better to cope with physical conditions not generally understood, advance the science, and bring to light, through continued publicity of the results of ground water investigations, much needed information.

GROUND WATER AND IRRIGATION

The widest economic use to which water is being applied in the arid and semi-arid regions is in irrigation. In California alone the increase in irrigated area in the ten-year period from 1909 to 1919 (the latest date for which a census as available) has been about 1,550,000 acres or an increase of about 60 per cent over that irrigated in 1909. Ground water developments have furnished a supply for about one-third of this additional area. That is, prior to 1909 only 350,723 acres were irrigated through ground water development, while that thus served in 1919 totaled 868,060 acres.

The question of ground-water supply for irrigation development is becoming increasingly important in the western states, as the surface water has all been appropriated and is being put to an increasingly beneficial use over larger areas with the agricultural growth of the region. It is usual, in most valleys, that supplies sufficient in quantity for domestic use and stock have been obtained practically everywhere, but when drawn upon for irrigation purposes, these supplies, in some localities, have been found precarious in nature. The demand for irrigation supplies, the ever increasing availability of ground-water because of improved methods of drilling and pumping, and the decrease in pumping costs, and the extensive financial outlay based upon pumped water supplies, have created a need for far more preliminary information as to the magnitude of ground-water supplies, particularly in relation to dependability or to annual recharge, than has been the practice in the past.

The safe yield of an underground basin has been a question seldom considered. It should be investigated and reported upon before money is expended in development. In California many large tracts have been developed into highly productive orchards, vineyards, etc., at great expense through the extraction of the ground water beneath the tracts, only to find that such development has exhausted the ground water supply of the area and that the future existence of the productive area, if it can be saved at all, depends upon the availability of an external source of water supply.

CITIES DEPEND ON GROUND SUPPLIES

Not alone in irrigation activities has the development of ground water as a source of supply been marked, but, especially during the period of deficient rainfall from 1918 through the past year, have the water supplies of most of the smaller towns and many of the larger cities been dependent upon underground sources. The city of Los Angeles drilled about ninety wells along the line of its aqueduct in Owens Valley from which it pumped ground water in quantity to augment its surface supply at that source. A larger proportion of its domestic water supply is derived from ground water sources in the San Fernando Valley and underflow of the Los Angeles River channel. San Francisco is supplied in part from ground water collected by means of a filter gallery in the Sunol and pumped from wells in the Pleasanton Valley. The latter source was more extensively developed and more heavily drawn upon during the dry year of 1924 than has been necessary heretofor. The period of deficient surface flow made necessary the operation of the well fields situated along the eastern shore of San Francisco Bay from Oakland to Alvarado in order that the demand upon the East Bay Water Company could be met.

DISPUTES OFTEN OCCASIONED

These larger developments involve extraction of ground water in such quantities that they are frequently the source of legal disputes. Unfortunately laymen financially interested in ground water developments and engineers who have designed, constructed, and operated such developments, seldom deem it necessary to have a thorough ground-water survey made during the projection of such enterprises. The engineer or geologist frequently finds himself called, however, in the capacity of expert advisor of the Court, or as arbitrator, to investigate and report physical conditions and facts after disputes arise as a result of ground-water developments.

The extraction of ground water due to pumping or infiltration galleries may so lower the water-table as to render neighboring lands less easily cultivated or even unfit for cultivation; cause excessive seepage from neighboring streams or ditches, thus depriving appropriators of the surface water of their rightful proportions of the flow, or cause users

of pumping plants to extend their wells and equipment to greater depth and greatly increase the cost of obtaining their rightful correlative proportion of the ground-water. These interferences have often been brought to the notice of the courts and the law has been defined in relation to the rights of the parties under various conditions through many decisions of the Supreme Court.

Must Find and Present Facts

In general it can be stated that every dispute arising in each locality is subject to the application of certain principles of law, modified by the specific conditions existing in the particular problem. The function of the engineer and geologist in such disputes is to investigate and present the facts in a manner readily understood by the layman and so enlighten the Court and users of water to the end that the ground-water resources will be protected and put to beneficial use to the development of as wide an area as possible. This can only be accomplished by making clear the nature and occurrence of ground-water, its behavior under the conditions obtaining, and the relation between discharge and recharge, to the end that laws will not be established unnecessarily to restrict the use or development of this natural resource, and, at the same time, to conserve it through the restriction of over-development or the deprivation of one locality to the advantage of another.

Again, not only in its development as a water supply is ground water presenting problems, but the spreading of surface water for irrigation purposes over areas of great magnitude, the control of streams through levees, and drainage of delta lands, have greatly modified natural ground water conditions. Irrigation and hydraulic engineers, after rather expensive and disastrous experiences with ground-water accumulations resultant from surface irrigation and excessive ditch seepage, and often from reservoir losses also, are beginning to recognize the necessity for thorough ground-water investigations preliminary to any plans of development or constructive work, and the inclusion in their plans of works designed to meet the changed conditions.

Problem Often Neglected

Generally the accumulation of ground-water and its removal has been considered by drainage engineers to be of relatively little importance in the larger drainage and reclamation projects in comparison with protection from the inroads of surface water during periods of heavy rains and high river stages or the removal of accumulated surface water. In other words the engineer is most concerned with the water which visibly affects the land and whose source is known. However, seepage water derived through downward percolation of stream overflow, levee or channel seepage from streams, direct percolation of rainfall, and the lateral movement of ground-water from porous adjacent and higher lying areas greatly affects the land. This effect may not be manifest as considerable visible amounts of water over any given land surface in any limited time, but, over the area as a whole, it is a most important factor in the reclamation or drainage problem because of the steady accumulation at a constant rate for all time.

In many drainage problems excess water may be due to causes which do not reveal themselves through surface observation as well as does that derived through the flooding of land by surface water, and ground water investigations are always of aid in the problem and the results obtained therefrom almost always justify their expense. Damage frequently results through the excessive application of irrigation water, excessive ditch seepage losses, the backing up of the ground-water through subsurface dams, or leakage from reservoirs, all of which generally cause a water-table rise which may be sufficient in extent to water-log certain lands.

Troublesome Questions Presented

The effect of artificial drainage and irrigation is to change ground-water conditions in a broad way, and such changes are inevitable in agricultural and commercial progress. However, questions do arise in this connection as to whether or not it is permissible for a land owner or group of land owners so to improve his or their holdings as to make them productive to the detriment or ruination of other lands. The drainage of certain lands may be so effected only at the expense of lowering the water-table to such depths under adjoining lands as to render them unprofitable producers or unfit for production.

On the other hand, irrigation may be so wastefully practiced on, or ditches so constructed and maintained over, certain lands as to cause a water-logged condition to prevail, through the accumulation of irrigation return water and ditch seepage, over areas of adjacent lower lying lands. The physical facts pertaining to such questions, corrective measures to be applied in such instances, and the measure of expected damage attributable to certain causes, are questions which should be ascertained through careful investigation before the development is undertaken. It is incumbent upon the investigator to determine the probable modifications due to the projected development, the measure of the modification, as to extent of effect, the cause and its measure, and, if possible, an adjustment through regulation of the cause so that no detrimental effects will result. This is seldom done prior to development but the effect of such developments have presented a variety of problems, both to the courts and engineers responsible for their projection.

This all indicates that the importance of ground-water problems in the agricultural and commercial development of the western and southwestern portions of the United States cannot be over-emphasized. If we are to progress, ground-water as a water supply resource will have to be conserved and developed to a far greater extent in the future.

Big Field for Research

The development of ground-water for water supplies appears to present few difficulties. The existence of this natural resource in abundant quantities is demonstrated by the countless springs issuing from mountain sides and valleys and the multitude of wells found in all settled regions. That water is present in the ground is therefore a matter of common knowledge, but its source, extent, direction and rate of movement, and ultimate disposal are little understood, not only by laymen financially interested in its development, but by most engineers as well, and, while the pumping of water from the ground seems extremely simple, the engineer has encountered many conditions, difficult of solution or impossible for him to solve, before water can be made available for continued pumping as a dependable supply.

This is an era of specialization and it is believed that the present trend of development, with the magnitude and diversity of the questions presented, justifies a specialization in ground-water problems.

Calls for Specialization

The science of ground-water hydrology is a body of organized knowledge collected from the other natural sciences, in its present stage of advancement, and not completely covered by the present academic training of either hydraulic and irrigation engineers or geologists. The engineer or geologist who finds his field broadening to include problems in ground-water hydrology, feels the handicap in the lack of knowledge of the essential basic elements which are controlling in such problems. It is a lengthy process to become qualified in ground-water hydrology through experience alone, and, furthermore, a little knowledge of, and experience in, ground-water hydrology is a dangerous thing, as it leads one to jump at conclusions which may or may not be justified by the facts.

Let us take as an example one problem in ground-water hydrology. It

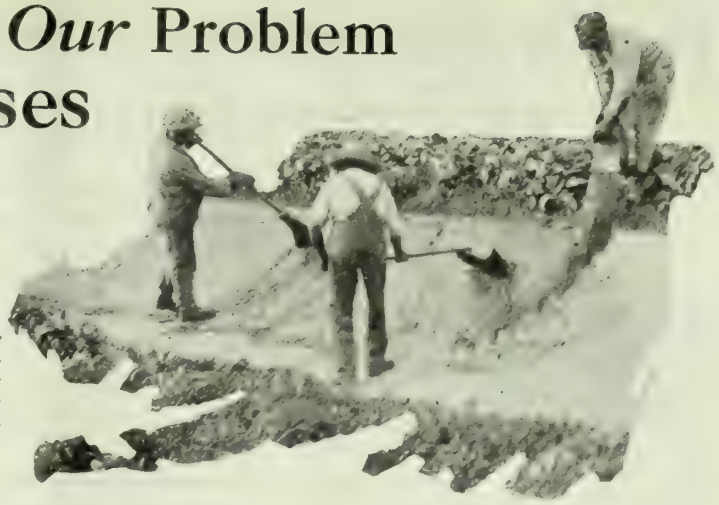
How We Conquered *Our* Problem of Leakage Losses

East Contra Costa Irrigation Company Reduces Water Waste By Repairing Ditch Linings With Cold Asphalt

By W. D. SULLIVAN
Manager, East Contra Costa Irrigation Company



Painting the sides of old concrete ditches with the pure asphaltic preparation.

THREE irrigation districts, comprising a total of 20,000 acres of land, are served with water by the East Contra Costa Irrigation Company, an old mutual water company that was formed before the districts themselves were organized under the Wright act. These three districts are known now as the Brentwood, Knightsen and Lone Tree Districts.

As manager of the districts, one of the greatest problems that has occupied my attention has been the high water loss from the canals, particularly in the high main laterals, where the water has to be raised through six stages of pumping to a height of 144 feet from the water level of the river. We use two-stage centrifugal pumps to lift the water, the capacity varying from 13 to 39 second feet, depending on the number of laterals that are to be served.

Large Losses Revealed

It can readily be seen that water, by the time it has traveled a distance of over six miles, and been lifted to a height of 144 feet, represents a comparatively high value per unit of measurement. Carefully kept records, for the year 1925, with its total of 204 actual pumping days, show that over the entire system we have suffered an average loss of almost 30 percent of all water pumped. And on our highest main lateral, a loss of 26 percent is shown.

This loss, occurring, as it does, on a ditch that had been lined about nine years, develops another interesting point that is worthy of consideration when we are discussing the question of linings. Our records, taken on every main lateral of the district, show that the percentage of water lost during the season was as high in ditches where the lining was broken up, as it was in ditches that had never been lined at all.

We were confronted with the necessity of taking some immediate action to correct this loss of valuable water, and we cast about for some method that we might utilize to repair the lining that still retained something like its original form, and to replace it in places where the old lining, laid about nine years ago, had completely disintegrated.

I do not believe the failure of the original lining was due to any one cause, but probably to a number of factors including the carelessness of the contractor who laid it. A two-inch concrete lining had been specified, but in many places the lining showed to be less than an inch in thickness, and broken pieces indicated that a very lean mix had been used.

What we required was some repair material that could be used as a lining, in places where an entirely new lining was needed, as a seal for cracks that had opened and a protective covering for the rest of the ditch.

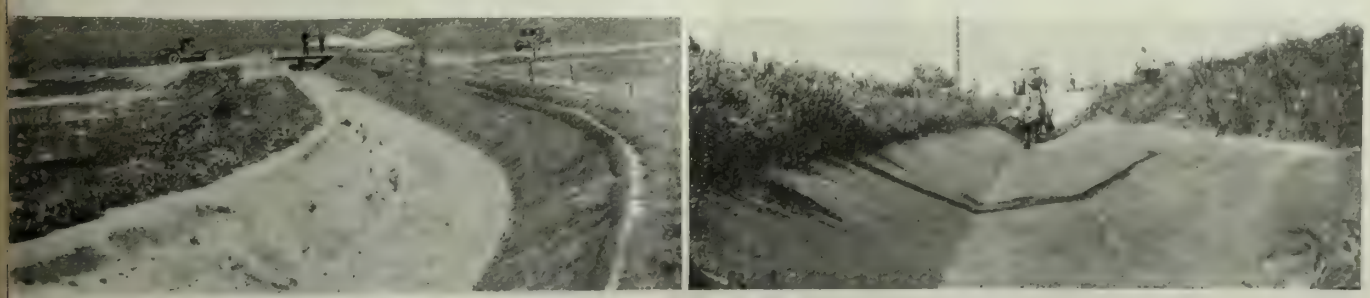
This we found, fortunately, in an emulsified asphalt that can be applied cold,—the trade name in fact is "Laykold,"—and which has been used considerably in this part of the state for repairing asphalt roads. As far as the finished job is concerned, the material looks and appears to stand up just like the more familiar hot mixture used in highway construction.

Experienced Contractor Chosen

This being our first experience with the material, we decided that it would be wise to let the job of applying it to a contractor who is familiar with the product. Malott and Peterson of San Francisco handled the work for us.

They brought one or two men with them, but for the most part were able to use our own men on the job. The material, which comes in barrels was mixed in an ordinary concrete mixer, where an asphaltic mastic was used. Where the preparation was used for painting and patching it was used directly from the barrels, the only mixing being a thorough stirring before it was transferred from the original containers.

The finished job gave us one of the cleanest and neatest looking ditches I have ever seen. At the present time water has been running through this particular lateral for just a few days and as closely as I can estimate, the water loss, which was averaging well over an acre foot per working day, has been reduced until it is now less than 25 percent of that amount. . . . And a large percentage of this loss is due, of course, to pumps running back and to leaky gates.



On the left, the concrete lining, nine years old. On the right, the new asphalt covering.

Is *Cultivation a Fallacy* as a Means of Preventing Evaporation?

Extensive Tests Cast Doubts on Traditional Value of "Mulch" as Conserver of Moisture

By F. J. VIEHMEYER*

THE QUESTION, "What becomes of irrigation water?" might be answered truthfully and in a few words without imparting much useful information. A consideration of the amounts of water lost from the soil in various ways and the importance and relation these amounts bear to the total quantity of water applied to the soil is much more complex.

The disposal of water applied to an orchard can be accounted for in a number of ways which may be listed as follows:

1. Losses in conveyance and run-off at lower ends of furrows or checks.
2. Evaporation losses from the free water surfaces while the water is being applied.
3. Deep percolation below the reach of roots.
4. Seepage losses along impervious strata below the surface.
5. Evaporation directly from the surface of the soil.
6. Water used by the plant.
7. Water remaining in the soil.

All of these losses with the exception of those listed in items 5 and 6 are more or less under the control of the irrigator and may be reduced by skillful methods to almost a negligible amount. However, every orchardist is concerned to know what portion of the total amount of water applied to the soil is used by the plant and how much is wasted by evaporation from the surface of the soil. For this reason the discussion will be limited to this phase of the question.

There is abundant evidence that under humid climatic conditions a large portion of the water from rains which falls on the soil is lost by evaporation. In fact, the records taken from the lysimeter experiments at Rothamstead in England which extend over many years and from similar experiments at Cornell university and elsewhere in this country show that as much as 60 per cent of the rainfall is returned to the atmosphere by evaporation from the surface of the soil. A knowledge of this fact has led many writers to stress the importance of these losses, and the need for controlling them by different kinds of mulches and by cultivation. For example, Hall, who was closely associated with the work at Rothamstead, in his text-book, *The Soil,* emphasizes the losses by evaporation and says that in some soils the capillary rise of water might be as much as 200 feet. Cameron states in his book, *The Soil Solution,* that the larger part of the water from rains in humid areas returns to the surface through distances of many feet. The statement will be found in Widtsoe's book, *Principles of Irrigation Practice,* that there is, soon after each irrigation, a steady upward movement of water, causing a general drying out of the soil to great depths. King in his several text-books and in many reports of the Wisconsin agricultural experiment station, and Hilgard and Longbridge in reports of the California agricultural experiment station, laid great stress on the losses of moisture through evaporation from the soil surface by upward capillary movement.

Of course, a much larger list of such references could be given but these examples are selected because they are more frequently quoted in the literature. There is one vital point to be noted in all of such references, and the one on which, in the opinion of the writer, rests the validity of the argument either pro or con, concerning the importance of evaporation losses and their means of control. This is, whether the losses by evaporation are confined to the surface layers of soil or whether there is an upward capillary movement of moisture from the lower layers and subsequent loss by evaporation. The large losses of moisture from the soil by evaporation in humid climates might be explained by the fact that much of the rain may come

Is Cultivation "the Bunk"?

That cultivation, in so far as it relates to moisture, may be necessary only to kill weeds, and keep the soil in a receptive condition to absorb rainfall, is the conclusion of Prof. Viehmeyer, as the result of the experiments which he describes in this article.

Cultivation, he declares, seems to have little influence in controlling the amount of water evaporated from the bare surface of the soil in the tanks used in the experiments at Mountain View, containing one-half to three-quarters of a ton of soil.

The supposed efficacy of cultivation in controlling evaporation losses is doubtful in any event, he says, since so large a portion of the total water loss occurs before the soil surface is dry enough to cultivate.

Cultivated and uncultivated soil, after exposure to evaporation for four years, without addition of water, retained approximately equal moisture content, and neither had been reduced below the wilting co-efficient except in the upper layers.

Transpiration is a tremendously greater factor in the loss of soil moisture than evaporation from the surface in either cultivated or uncultivated soils, believes the author. "Most of the water applied to the soil occupied by roots remains in the soil until it is taken out by the plant."

*Professor Viehmeyer is attached to the Division of Irrigation Investigations and Practice, University of California. The accompanying paper was delivered before the recent Citrus Institute, at San Bernardino, California.

in small amounts which do not penetrate very deeply into the soil. When these light rainfalls occur in the warmer parts of the year the atmospheric evaporating power is high and the soil will quickly dry out. It is clearly evident that almost all of this water may be lost in this way and only that which penetrates deeply into the soil will remain. The situation in the arid and semi-arid regions of the west is quite different. In California the rains come when the atmospheric evaporating power is low and even though the amount of rain over the greater part of the state is light most of it penetrates deeply into the soil. Furthermore, the usual practice is to apply water in sufficient amounts to wet the soil to considerable depths and that part which remains in the surface layer and rapidly evaporates is a relatively small portion of the total amount applied.

What is the Utility of a Mulch?

It will be noted in the references cited that it is believed that losses of water are occasioned by the upward movement of moisture from the lower moist layers of soil and that this belief is based upon the familiar teaching that moisture is capable of moving in the soil in all directions through capillary forces. The part cultivation is supposed to play in preventing the upward rise and consequent loss of moisture into the atmosphere is based upon the theory that by loosening the surface, rapid drying takes place and the soil particles are removed from close contact with one another. The first condition is thought to shut off evaporation because the dry soil is assumed to act as a blanket; the second, reducing the points of contact is believed to lessen the capillary pulling power. A great many references may be cited in support of this basic idea and almost as many in refutation of it. Certainly it is difficult to understand the justification of a statement made in a very recent paper dealing with this subject that "Where the mulch is measured solely as a retentive agent, as under irrigation, the evidence is unanimous that its effect is positive in saving moisture."

The movement of moisture in soils contained in glass or metal cylinders and columns of soils in tanks or metal lined flumes, when the lower ends are in contact with free water has received much study. The movement of moisture from moist soils into soils containing lesser amounts of moisture, the field conditions more frequently met with in California, has received considerably less study. However, the published results of most of such studies indicate, although some of the investigators did not come to this conclusion, that the movement of moisture, especially in an upward direction, from moist soils to drier soils is slight in amount and extent within periods of time with which orchardists are concerned, and when the source of the moisture supply is not saturated soil in contact with a free water surface.

Numerous observations of moisture conditions found by sampling field plots have been reported and, in many cases, the upward movement of moisture by capillary action and evaporation losses have been held to be very important. On the other hand equally good evidence has been advanced that comparatively little water which has passed below the first foot of soil is lost by evaporation and that the loss of moisture takes place largely through transpiration. Sewell, of the Kansas agricultural experiment station, in 1919, published in the *Journal of the American Society of Agronomy* a review of much of the literature dealing with tillage not only in its relation to moisture conservation but also in relation to its other supposed effects on the soil and plants. Sewell concludes "that the prevailing theories advocating deep plowing and frequent cultivation are not founded upon experimental evidence" and that "cultivation may be necessary only to kill weeds and keep the soil in a receptive condition to absorb rainfall." This, in so far as it relates to moisture, is the conclusion reached by the writer from the results of experiments, some of which are presented below.

Tests Determine Losses

At Mountain View, in the Santa Clara Valley, clay loam soils were packed in tanks which contained from one-half to about three-fourths of a ton of soil. The tanks were arranged in trenches and could be conveniently weighed by means of a portable derrick and suspension scales. Water was applied to the surface of the soil in the tanks and as soon as the surfaces were sufficiently dried, some of the tanks were cultivated by stirring the soil to different depths. The soils were thoroughly cultivated every week until the end of the test. In other tanks the soil was undisturbed except to remove any weeds which grew. The losses of moisture in pounds per square foot of surface of soil are given in Table 1. The water was applied to each tank on August 17, 1921, and the results of some of the weighings are given in the table.

Table 1—Average losses of moisture by evaporation in pounds per square foot from the surface of bare clay loam soils, in tanks at Mountain View. Water was applied to soil August 17, 1921.

	August			September					October	November	
Treatment of Soil	25	27	29	2	10	16	24	30	8	1	4
Undisturbed except to pull weeds	4.6	5.0	5.4	6.1	6.8	7.4	7.8	8.4	8.4	9.3	9.4
Cultivated weekly to depth of 6 inches	4.5	5.0	5.4	5.8	7.0	7.2	7.8	8.4	8.4	9.4	9.8
Cultivated weekly to depth of 8 inches	4.8	5.0	5.4	6.0	6.6	7.2	7.6	7.8	8.0	9.3	9.5
Cultivated weekly to depth of 10 inches	4.3	4.9	5.0	5.4	6.0	6.6	7.0	7.3	7.3	8.4	8.7

Table 2—Percentages of moisture in soil in tanks at Mountain View, 80 days after irrigation.

	Depth of Soil Samples in Inches					Depth of Soil Samples in Inches			Average in Depth of
Treatment of soil	0-4	4-8	8-12	12-16	16-20	0-12	12-24	24-36	0-36
Undisturbed except to pull weeds	9.4	15.3	17.7	19.2	19.0	13.9	18.8	18.7	17.0
Cultivated weekly to depth of 6 inches	9.7	18.9	18.9	19.0	20.6	15.3	20.4	20.0	18.8
Cultivated weekly to depth of 8 inches	8.9	15.2	18.2	17.2	19.8	13.0	19.4	17.1	16.8
Cultivated weekly to depth of 10 inches	7.5	14.8	16.9	18.1	17.4	13.0	17.4	18.1	16.5

Table 3—Summary of soil moisture contents in 3-foot depths, in acre inches per acre in the cultivated and uncultivated plots at Davis, irrigated August 2, 1921

Depth of Soil Samples		Aug. 3	Aug. 5	Aug. 8	Aug. 26	Sept. 23
0-3	Cultivated	11.09	9.83	9.50	8.56	8.46
	Uncultivated	11.94	10.44	9.88	9.13	8.33
3-6	Cultivated	8.94	8.38	9.36	8.99	8.52
	Uncultivated	9.59	9.08	8.85	9.03	8.70
0-6	Cultivated	20.03	18.21	18.86	17.55	16.98
	Uncultivated	21.53	19.52	18.73	18.16	17.12

One pound of water per square foot is equivalent to depth of about 3-16 inches. The average losses from the tanks differed approximately by this amount which probably was within the experimental error. The average loss from the uncultivated soils in the 80 days was 9.4 pounds per square foot which also was the average loss from all of the cultivated tanks when they were grouped together without regard to the depth of cultivation. It is apparent, then, that cultivation seems to have little influence in controlling the amount of water evaporated from the bare surface of the soil in the tanks.

It should be noted from the data in Table 1 that the loss which occurred within the first week after the water was applied was approximately one-half of the total loss which occurred within 80 days, a period usually longer than that between irrigations. This rapid loss immediately following irrigation is further illustrated by the records obtained from tanks with bare undisturbed soil exposed to evaporation for the entire summer of 1922. These tanks were irrigated on May 14, with sufficient water to saturate the bottom 6 inches of soil in the tanks. The average loss during the week

following irrigation was 13 pounds. The accumulated loss at the end of the first month was 19 pounds. The total loss for the entire 164 days or from May 14 to Oct. 26, was 33 pounds. The surface of the bare soil in these tanks was undisturbed except to pull weeds. These rapid losses of moisture by evaporation from these loam soils in many instances occurred before the soil could be properly cultivated. It will be seen, then, that the supposed efficacy of cultivation in controlling evaporation losses is doubtful in any event since so large a portion of the total loss for long periods occurs before the surface is dry enough to cultivate.

Four Years' Observation

Several of the tanks were kept under observation for a long time. One of these, containing Yolo clay loam which had an area of 3.01 square feet exposed to evaporation. The tank was irrigated on Aug. 17, 1921, and the surface of the soil was undisturbed except to pull weeds. It was covered during rains to prevent the addition of water after the initial irrigation. The total accumulated loss of moisture at the end of the different periods was as follows: Loss at end of first week, 12 pounds; 6 months, 29 pounds; 12 months, 33 pounds; 18 months, 40 pounds; 24 months, 44 pounds; 36 months, 51 pounds, and at the end of 51 months, 57 pounds. The total loss of 57 pounds which is 18.9 pounds per square foot is equivalent to about 3⅜ inches in depth for a period of over four years. The soil moisture after four years' exposure to evaporation had not been reduced below the wilting coefficient except in the upper layers.

It has been possible to make a number of comparisons between the losses of moisture from cultivated and uncultivated soils in tanks under the atmospheric evaporating condition at Davis, in the Sacramento Valley, as well as at Mountain View. The results have been the same as these obtained at Mountain View in that the losses were substantially the same whether the soil was cultivated or undisturbed. During 1923 and 1924 a sandy loam soil, which was much lighter in texture than any soil previously used, was packed in the tanks. The losses of moisture from the bare soils were determined for a period of 11 months. The average loss during this time was 51 pounds per tank, or 13.8 pounds per square foot of area exposed to evaporation. This loss is greater than that from finer textured soils, clay loams. The evaporation losses observed in field trials also were greater from the sandy soils.

The soils in the tanks at Mountain View, data from which are given in Table 1, were sampled to ascertain the distribution of moisture 80 days after the water was applied. The results are presented in Table 2.

Main Loss from Top Layer

Apparently there is little difference in distribution of moisture in the soil in the cultivated and uncultivated tanks. The majority of the loss seemed to be confined largely to the upper 4 inches of soil. It will be noted that below 8 inches there were very uniform percentages of moisture even 80 days after irrigation. One of the tanks which was under observation for more than four years after the application of water and which was covered during rains was sampled at different times. There was a gradual loss of moisture throughout the entire depth of soil but rate of loss was extremely slow. It can not be assumed that these losses from below the surface layers are due entirely to upward capillary movements or to loss by water vapor movement. It was assumed for many years that the water lost from the soil by water vapor was extremely small and any losses which did occur from the deeper layers was attributed to capillary movement. However, recently evidence has been advanced which seems to show that considerable aeration of soils takes place due to atmospheric pressure changes and it is possible that the slight losses of moisture from the deeper layers of the soil used in these experiments may have been due to movement of air and water vapor through them.

Test Field Losses

Trials with field plots were also made to determine the loss of moisture by evaporation from the soil. The plots were located at Davis, on Yolo loam soil; at Mountain View, on Yolo clay loam; at Delhi, the San Joaquin Valley, on Oakley fine sand, and at Whittier, on Yolo clay. These locations represent a wide range of climatic conditions and the soils differed markedly. At each place four plots were laid out. Each plot was 90 feet long and 20 feet wide, separated by a strip 10 feet wide. The plots were irrigated so that there was an even distribution of water in each and as soon as the surface had dried sufficiently two plots were cultivated and the surface of the soil in the other two plots was undisturbed except to pull weeds. The cultivated plots were thoroughly cultivated at weekly intervals throughout the period of the test.

A summary of the moisture contents in the plots at Davis are given in Table 3.

Some of the results of sampling the plots at Whittier are given in Table 4. The results of all of the field plot studies indicate that no loss of moisture occurred from the soil in the depth of 3 to 6 feet. Sampling in depths of one foot at Davis, further show that the losses were confined almost entirely to the upper foot of soil. Samples taken in depths of four inches approximately two months after the water was applied in the field plots likewise clearly show that the losses of moisture by evaporation occurred largely in the upper eight inches of soil and the greater portion of the loss from this depth was from the first four inches.

The data presented in Tables 3 and 4 are typical of the results obtained in all of the field plot trials. Some of the tests were run for longer periods and were repeated. The results show that the loss of moisture by evaporation from the surface of the soil under California conditions is not very great and that cultivation did not influence the amount of water lost or the distribution of moisture in the soil.

Plants Grow After 80 Days

The presence of relatively large amounts of water in the clay loam soils in the tanks which have been described, even after long exposure to evaporation, has been demonstrated. Sixteen of 20 tanks which had been irrigated August 17, 1921, were planted to vetch and barley after having been exposed to evaporation for 80 days. The upper four inches of soil was too dry to germinate the seeds which were planted on November 4. Therefore, a small amount of water (less than one-half gallon) was added to start the seeds. The plants were thinned after they were up so that there was a definite number of plants in each tank which gave a stand comparable to that usually obtained in an orchard cover crop. Satisfactory crops were produced in each tank. During rains the tanks were covered by means of a canvas drawn over a frame. The loss of moisture by evaporation during 80 days previous to planting the seeds had not been sufficient to prohibit the maturing of cover crops. There seemed

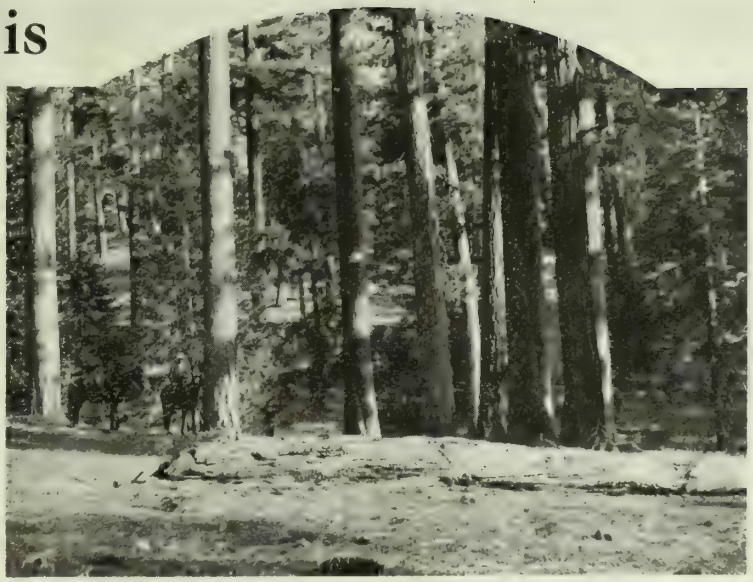
Public *Knowledge* is the *Forests'* Need

Advertising Clubs of the World, Through Committee on Reforestation, Assist in Spreading Information

By MALCOLM MUIR

Chairman of the Reforestation Committee of the Associated Advertising Clubs of the World.



Virgin forest, of the type fast dying out in the United States. (Photo by U. S. Forest Service.)

BELIEVING that the greatest single need to solve the problem of reforestation is a realization, by the entire population of the United States, of the magnitude and importance of the emergency, and the necessity for drastic action, the Reforestation Committee of the Associated Advertising Clubs of the World is co-operating closely with the National Forestry Committee to arouse that public interest which is so essential to the problem's solution.

This year, in addition to spreading the gospel of reforestation throughout advertising organizations all over the nation, the reforestation committee is encouraging members of advertising clubs in all parts of the country to co-operate in actually planting trees, thus setting a practical example, which, it is hoped, will be followed by other organizations actively interested in the national welfare.

Agriculture Depends on the Forests

The Associated Advertising Clubs of the World recognize that a question of rehabilitating our forest resources involves a great deal more than merely conserving materials for building houses, making paper, and for the many other purposes for which forest products are used. On forest conservation depends, to a large extent, the success of the basic industry of the United States—agriculture.

Picture the millions of hillsides of the country as covered with sponges, which, during the rainy season, become filled with water which is retained as in a gigantic reservoir and released gradually during a drought. Such a picture presents the function of our vast forests in aiding agriculture in a way that can never be adequately supplanted by any other agency.

Open the pages of history of those countries which have ruthlessly destroyed their forest resources, and you will find that the most glaring example undoubtedly is that of China. With no thought to the future, the Chinese people were permitted practically to denude the entire country, and China's backward position among the nations of the world, the frequent famines, and comparative destitution, are largely due, economists say, to its forestry situation.

The United States Forestry Bureau goes so far as to place the conservation of water supply as the most important function of the National Forest. In the report on government forest work the forestry service says, "Undoubtedly the greatest value of the mountain ranges in the country, most of which are within National Forests, lies in their influence upon the regularity of the water supply. In many of the states the mountains afford the main water supply for domestic use, for irrigation, and for the development of power. The future development of the entire country, therefore, will depend upon the amount of water and the manner in which it flows from the mountains."

Pacific Coast Has One-Half Timber

The extent of the cutting out of our original forests in the United States may be understood when it is said that less than five per cent of the virgin forests of New England and but twelve per cent of her original stand of timber now remain. New York, a leading state in lumber production in 1850, now manufactures only 30 board feet per capita yearly, or not more than a tenth of the requirements of her own population and industry. The original pine forests of the Lake States, estimated at 350 billion feet, are now reduced to less than eight billion. One half of the timber remaining in the continental United States is in three states bordering the Pacific Ocean.

The vegetable covering has a very decided influence on run-off. For this reason Congress made the preservation of conditions favorable to stream flow one of the principal objects in the establishment and administration of the National Forest. Many communities have entered into cooperative agreements with the Forest Service for the better protection of the water-sheds from which they get their supplies.

Rainfall is not so rapidly evaporated or drained off in forest regions, the moisture gets into the soil there, and the force of the wind is broken. Consequently, a forest country avoids much of the seasonal aridity that marks an open country with an equal amount of rainfall. The removal of the forests has thus emphasized climatic effect in some countries resulting in their virtual sterilization. In addition to China, Spain, Siberia, Algeria and North Africa are commonly cited as illustrations of countries whose productiveness has been reduced by the denudation of the forests.

President Coolidge, addressing the first conference on the utilization of forests, said, "Fully one-fourth of our land area ought to be kept in forests—not poor, dwindling thickets of shrub, but forests of trees fit for bridges, houses and ships. Idle forest land has scrapped schools, factories, railroads and towns; it has dotted the land with abandoned farms, it has created a migratory population. Our forest problem is a land problem of the first magnitude."

Drastic Action Necessary

Since the depletion of our forests has not resulted primarily from a practical

Vol. II MAY, 1926 No. 5

A Vital Interest

SECRETARY WORK, in prefacing his Los Angeles address on the question of the Colorado River developments, said: "I have come to the West to meet and talk with its representative people, and because I believe that I have something important to say to them."

The audiences that greeted him in Los Angeles and San Francisco left no doubt in his mind as to the importance which they, also, attached to his message. In the gatherings which he addressed there were those who agreed with him heartily and those who were doubtful of the wisdom of the commitments which he has made. But there was no division on the question of the importance of the whole matter.

Every state that is to share in the distribution of the Colorado's much needed waters, every individual or corporation that has taken a stand either for or against any projected plan of development, should, for self-interest if not for the welfare of the entire southland, be deeply anxious for an immediate settlement upon some plan of operation that will break the impasse which has existed for so many years.

Dr. Work's remarks, whether one agrees with all of them or not, are of the utmost importance because they point in the direction of definite progress toward a possible use of the River that is now wasting a large part of its value.

Will Congress Act?

ALTHOUGH the favorable report of the senate committee was undeniably a victory for the proponents of the Swing-Johnson measure, it by no means settles the question. As a matter of fact there is little chance, if any, of congressional action before adjournment in June.

The prospect seems favorable for some action by the House Committee after Congress re-convenes, and when the measure is brought to the floor of the two houses, there will be an opportunity to find out what its chances for success actually are. It still has obstacles to overcome. The westerners who comprise the irrigation committees are naturally more prone to give favorable consideration to such a measure than the representatives of eastern and southern states whose attitude toward reclamation is often extremely skeptical.

Whatever is the outcome, the rate of all reclamation and irrigation progress ought to be materially accelerated by definite action. Secretary Work broadly suggested that government construction and operation was not the only way out, that government supervision was an essential, but that some "organized corporation" might possibly be able to advance plans for the construction of the proposed works under private auspices that would deserve sympathetic consideration.

If the waters of the Colorado can not be made to yield their potential worth to the west under one plan, they should be made to do it under another. The essential thing is to get action. Public opinion in the west, at least, seems to be pretty much convinced of that, and a decision within the next year seems now to be definitely possible.

Freakish Finance

A CONTRIBUTOR to this issue points out that there must be something wrong in the attitude of the investing public toward irrigation values, to judge from the relative quotations on municipal security issues of cities compared with those of irrigation districts. As an instance he points out that bonds of the City of Merced, California, are being sold on a basis that yields 4.40 per cent to the investor, while in the same market bonds of the Merced Irrigation District yield almost six per cent.

In other words, it costs more to finance irrigation developments than it does to float security issues of other forms of municipal enterprises, and in this case the comparison is made doubly effective by the fact that the Merced Irrigation District includes the city of Merced, and in addition about 180,000 acres of valuable irrigable land.

His point is that the investor has been deluded by a fiction of danger that has surrounded irrigation securities. Whether this fiction has been artificially created or has grown up naturally out of the

POINT *Of* VIEW

checkered history that has occasionally attended investments in irrigation securities, it is nevertheless a fact, and it is the responsibility of the irrigation industry to dispell it.

Irrigation has had its failures and its insolvencies, as has every other industry. But that is no reason why districts with everything in their favor from a business standpoint should be penalized in their financing operations.

The Value of a Tree

IN ANOTHER part of this issue, a contributor tells something of what is being done by a committee of the Associated Advertising Clubs of the World in the way of disseminating information and creating a wider public interest in the problem of reforestation. In undertaking this work, the advertising men have embarked upon a splendid enterprise.

Their immediate interest, of course, is in conserving the most vital raw material that is used by their profession. In a sense, their concern in the preservation and restoration of the forests is selfish, but, in a larger sense, it is a generous and patriotic move for the welfare of the whole people.

All of us, indeed, are interested in reforestation from a motive that is selfish in the last analysis. But it is a fortunate thing when we can, in advancing a movement which has such a vital tie-up with our own necessities, also contribute to the best interests of the whole nation, and help to conserve a great economic, social and aesthetic resource.

The Fire Menace

WE ARE hearing a great deal about reforestation lately, but not so much about the 50,000 acres of land that are cut over each year by private logging operations, forty per cent of which are left in an unproductive condition. There are one and a quarter million acres of waste or brush land in California alone that are not producing anywhere near the crop of timber that they should. These lands are the result of two factors that constitute a grave menace—improper lumbering methods and repeated forest fires.

Many of these acres will have to be reforested. But what about the acres that are being cut-over this year, and will be cut-over next year? The solution to this problem depends upon the lumbermen leaving seed trees, protecting young growth and excluding fire from cut-over areas.

Reforestation is a big national problem, but in the far west it is secondary to fire prevention, for in the high mountains of the Pacific Coast, nature will attend to reforestation if given a fair chance. In the redwood region, planting is of course necessary, since clear cutting of the stand is practiced.

The trouble is that nature is not given a fair chance. The careless campfire, and the deadly cigarette, are still destructive in spite of the careful work that is being done by the protectors of the forests.

How About Cultivation?

PROFESSOR VIEHMEYER'S article, a republication of a paper presented to California citrus growers recently, will undoubtedly elicit a good deal of interest from readers of this magazine. There is no axiom of agriculture more widely accepted than that irrigated land should be cultivated, as soon after the application of the water as it is possible to get on the land, in order to prevent the evaporation of the moisture which has been introduced at such cost of time, effort and money. Professor Viehmeyer's experiments would indicate that this impression is an unscientific one.

In his article he is satisfied with presenting the results of his experiments, without making the "inductive leap" that would generalize too broadly from the particular data adduced, and merely suggesting the obvious inferences which his surprising results seem to justify. He has not tried to say the last word on the subject, and that last word will probably not be said for a long time. He has, however, opened up for discussion a problem of great practical interest to every irrigator. Whether cultivation is as effective as a preventive of evaporation as is generally conceived, or whether it is as negligible as his laboratory experiments seem to indicate (for most of the experiments were on a laboratory scale); or whether its value lies between these two extremes, the practice of irrigation will be well served by approaching the problem from the scientific standpoint, and finding out actually what occurs, and exactly what the value of cultivation is, not only as a moisture control, but in every other way in which it serves the farmer.

Walla Walla Responds

THE BURBANK and Attalia irrigation districts, in Washington, have been hard pressed to meet their financial obligations. Recently it looked as though the families living on the projects—104 of them—would have to surrender their holdings and move away. Warrants were five or six years behind. The water was to be shut off if payments were not made. Only a few thousand dollars were needed to meet the temporary emergency, but these few thousands seemed as far away as so many millions.

Representatives of the two districts appeared before the Walla Walla Chamber of Commerce at its meeting on April 13, and told their story in a matter-of-fact way. Before the meeting had adjourned, the business men of that city had subscribed the needed thousands, and the funds for tiding over another year were assured. The Northern Pacific Railway led the subscription list with a pledge of $1000.

It was a generous thing, but if, as is probable, the districts may be rehabilitated, the families saved to the Walla Walla region, and the 2500 irrigated acres prevented from reverting to a desert condition, it was a wise thing, as well.

San Joaquin River to be Turned Upside Down

(Continued from page 14)

lands that could be so irrigated, for the bulk of these lands lie from three hundred to six hundred feet above sea-level.

Further study has evolved a superior plan that would employ the channel of the San Joaquin River as a conduit. Instead of excavating a huge canal on the west side of the valley, the present river channel would be utilized by placing low dams with adjacent pumping plants, at intervals along its entire length. The dams would form a series of ponds in the river channel each nine to eighteen miles long and each successively about ten feet higher than the one before. The pumps at each dam would boost the water from the lower to the higher levels. Fourteen such dams would carry the water one hundred fifty-four miles southward against the grade of the valley floor to the mouth of Fresno Slough. The average static lift at each dam would be 11.3 feet and the entire series would raise the water one hundred and fifty-nine feet above sea level. This series could be extended southward in Fresno Slough for sixty miles further. Southward from here, through the Tulare Lake basin, a canal would have to be excavated since there is no suitable natural channel in this section of the valley floor.

To Run Up the San Joaquin

This method of employing the San Joaquin River channel as a conduit for boosting the Sacramento water up the grade of the San Joaquin Valley floor, would cost less than half as much as the grand canal of the first method and would furnish a much more flexible system of works for progressive development. Also it would promote the conservation of water, for these dams would stop all unused water in the tributaries of the San Joaquin from running to waste; the maintenance and operation costs would be much less than those of a grand canal and a very serious objection to the grand canal, that would become of increasing importance as the San Joaquin Valley becomes more thickly populated, would be overcome. This objection is the creation of a new obstacle to communication and traffic on the valley floor. A grand canal of dimensions sufficient to carry the large volume of necessary water would create an unbroken obstacle to traffic through the entire length of the valley and divide the valley floor into three long strips of land instead of two. The employment of the present river channel creates no new obstacle to communication and saves for future use very considerable areas of rights of way that would be occupied by a grand canal. Also, if it should become desirable, such a series of dams could be adapted to the employment of the river for navigation. At the present time there is practically no navigation on the San Joaquin River except in its lower reaches. By constructing locks at each one of the dams the river could be made navigable the year round.

Economy to Be Served

Since the bulk of the lands of the San Joaquin Valley needing an outside source of supply lie at elevations of more than two hundred feet above sea-level, a heavy pumping charge would be entailed if the Sacramento River water were pumped directly onto these lands. It is found that this can be avoided to a large extent by pumping the Sacramento River waters onto the lower lying lands in the San Joaquin Valley that are now irrigated from San Joaquin River waters. By serving these lower lands from the Sacramento River, the equivalent amount of waters served them could be diverted southward by gravity from the high elevation on the valley rim at which the San Joaquin River emerges from the mountains. Irrigation on the lower lands in receiving the equivalent to their customary supply would not be affected by the exchange. Studies of a first unit of such a plan for importation of Sacramento waters into the San Joaquin show that three hundred and forty feet in pumping lift could be saved by effecting such exchanges in supplies.

Map Illustrates Plan

The accompanying map (page 13) shows the outlines of the plan for such a first unit. Four great foothill reservoirs on tributaries of the Sacramento River are indicated, either of which might be used for storing surplus waters in the Sacramento Valley. There are also other reservoirs that would be serviceable for the same purpose. The general location of the series of dams in the San Joaquin River is indicated on the map. These dams would keep the channel of the San Joaquin River filled with water for the entire distance and the projects now diverting water from this channel would receive water supplied by the pumping plants boosting from one pond to the other, while the natural flow of the San Joaquin River would be diverted southward at a high elevation near the Friant Reservoir.

The canal carrying the San Joaquin water southward passes through an area now irrigated from the Kings River. By serving this territory with San Joaquin water and diverting the Kings River water at the high elevation of the Pine Flat Reservoir, a gravity canal can be run southward to a point two hundred miles into the San Joaquin Valley. Thus by providing a system of exchange of waters that would fully protect present users in the San Joaquin Valley, a new supply could be carried two hundred miles into the San Joaquin Valley to lands lying from two hundred and fifty to three hundred and fifty feet above sea-level with a static pumping lift of one hundred and sixty feet or less.

In describing this plan in a report to the 1925 Legislature it was stated "the studies reveal that only by completely co-ordinating the development and use of waters in both the Sacramento and San Joaquin Valleys can these plans be successfully and economically carried out." Responding to the recommendations in this report, the Legislature appropriated additional sums for developing the facts necessary for maturing final recommendations. These studies are now in progress.

Fundamentals of Management

(*Continued from Page 12*)

and Treasurers, being elective officers, sometimes offer more or less delicate problems in the supervision of their offices but the executive should remember that, after all, the directors are really responsible for all district affairs and with their support and through judicious co-operation all such matters can generally be resolved to reasonable substantial and effective business routine. The reconciliations of all accounts through the Secretary's office and the executive's contact with the auditor's activities generally afford substantial assistance in these matters.

One of the important duties of an executive is that of preparing the budgets for district expense. There seems to be but little excuse for material mistakes in such an effort and through such budget data and adequate valuation data, for assessment purposes, the directors can be assured that their tax levies are fully justified and sufficient.

The foregoing ideas follow closely the procedure exacted by any substantial corporation. If district executives proceed generally thus to discharge their responsibilities they will not only develop a measure of satisfaction to themselves but will gain the confidence and energetic support of all responsible employees, will receive generous and helpful support and guidance from their board of directors and, as a rule, may anticipate much helpful co-operation among the water users.

THE HYDRAULIC DIGEST

A Monthly Bulletin Board of Brief Facts and Events from Far and Near

Pacheco May Build System

Pacheco, California, one of the oldest towns in Contra Costa County, is planning to construct a city water system. Private systems now supply most of the residents, but are proving inadequate.

Pipe Comes from Alabama

Fifteen thousand feet of water-pipe has been shipped from Birmingham, Alabama, for use in Bellingham, Washington, which is making extensive improvements in its water system. The pipe order involved a cost of $40,000.

Orange Will Vote May 19

Faced by an impending water shortage, the city of Orange, California, has called a special election for May 19, at which a proposal to issue $125,000 in bonds for the improvement of the city's water system will be submitted to the electors.

Chelan Growers to Organize

Farmers in the Chelan (Washington) region have presented a petition asking for permission to form an irrigation district to be known as the Chelan River Irrigation District. About 600 acres wll be included. Twenty-eight petitioners are represented.

To Vote $91,000 Bonds

The board of directors of the newly formed Ramona Irrigation District (California) in response to a petition from land-owners, asking for a bond election at which $91,000 in bonds will be submitted to a vote to provide funds for the construction of works for the district, have set May 4 as the date for the election.

Bids Invited on Big Job

Bids on construction contracts which will probably total about $800,000 have been called for by the Nevada (California) Irrigation District, one the basis of specifications adopted by the district. The work to be contracted ranges from building a four-mile 60,000-volt power line to clearing land and building cottages. Metal and wooden flume construction is a feature. Bids will be opened early in May.

Establish Morro Water District

Supervisors of San Luis Obispo County, California, have established the Morro Water District, comprised by Morro and Morro Heights, and in May will set the date for an election at which the matter of organizing such a district will be submitted to the voters within its limits.

Will Reclaim 2,000 Acres

Two thousand acres of tide-land at the mouth of the Chinook River, Washington, will be reclaimed as the result of a decision of the federal War Department to allow the construction of a dike across the mouth of the river. A dike 1,000 feet in length will exclude tidewater and the channel of the river will carry off its normal flow.

Reduce Whitestone Project

The Whitestone (Washington) Irrigation District, has been reduced to include only 2500 acres, and the landowners will meet a construction charge of $100 per acre. The district will issue $250,000 in bonds, which will be accepted by the state in full settlement of the district's obligations. The cost of the project was $750,000.

Director's Seat Threatened

Suit was filed in April—and subsequently dismissed—seeking to remove W. O. Blair of Calipatria from his post as director of the Imperial Irrigation District. The abortive action was predicated on a decision rendered a year ago by the Superior Court, and appealed by Mr. Blair, by which his opponents claim that the director's seat was legally awarded to Mack Trentham.

Submits $17,000,000 Program

Supervisors of the city and county of San Francisco are studying a proposal submitted by M. M. O'Shaunessy, city engineer, providing for a $17,000,000 water improvement program, to extend over several years. The most pressing need included in the program is the purchase of 74 acres of land needed for the Glen Park reservoir, and the creation of 500,000,000 gallons storage capacity by construction of the reservoir.

Outline Deer Creek District

Plans for the formation of Deer Creek Irrigation District, in Tehama County, California, are outlined in a petition presented by property owners to the county supervisors. Thirteen land owners join in the petition. Water for irrigation will be obtained by diversion from Deer Creek and tributaries.

Plan $12,000,000 Project

Plans submitted to the Moorpark-Conejo Irrigation District, in Ventura County, California, by Edward R. Bowen, Engineer, estimate the cost of the proposed irrigation system at $2,316,000 and recommend it as feasible from an engineering standpoint. The plans involve diversion from the waters of Sespe Creek, and the estimate includes the cost of a distributing system within the district.

Water in Hetch-Hetchy Line

Water is now running for the first time through the transbay pipe line of the San Francisco Hetch-Hetchy project. It is not Hetch-Hetchy water, however. The pipe is being used temporarily by the Spring Valley Water Company under the terms of the option agreement by which San Francisco may purchase the system when the Hetch-Hetchy project is completed. The submarine section of the bay line is 2700 feet long.

Farmers Operate Boise Project

The transfer of the operation and maintenance of the Boise (Idaho) Reclamation project to its water users has been practically completed, it has been announced by the Interior Department. The Boise project is the first large federal project to be turned over the farmers for operation in accordance with the new reclamation law. Operation will be under management of a board of central control composed of representatives of the three districts which have entered into a contract with the government for assuming the responsibility of the project's management.

HYDRAULIC ENGINEERING

Dealing with the Practical Problems of the Operating and the Consulting Engineer

Agricultural Engineers Gather as California's Guests at Lake Tahoe, June 23 to 26

SEVERAL HUNDRED of the most prominent agricultural engineers of the United States, coming from every corner of the country, will gather in convention in California next month, when the American Society of Agricultural Engineers holds its annual meeting at Lake Tahoe, June 23 to 26.

The Lake Tahoe meeting will be the first meeting of the organization to be held in California, and it is accordingly creating much interest, both in California, where Pacific Coast members are planning in large numbers to avail themselves of the unusual opportunity presented, and throughout the United States, where the fame of Lake Tahoe and the prospect of a visit to the Golden State, added to the attraction of the annual sessions of the society, combine in an almost irresistible appeal.

Professor L. J. Fletcher, head of the Division of Agricultural Engineering, College of Agriculture, University of California, who is Chairman of the Meetings Committee of the Society, is arranging the program for the Tahoe gathering, in conjunction with the chairmen of the five main divisions of the organization. The preliminary outline of the program includes an array of practical discussions and reports, and a schedule of entertainment, that will intensify the desire of agricultural engineers to be present. All sessions are to be open to everyone interested, regardless of membership in the Society.

Inspection Trips for Visitors

Several hundred delegates are expected from outside of the state. These visitors will be especially interested in California accomplishments in irrigation, reclamation and electrical development. Accordingly, the Pacific Coast Section of the Society, which has the meeting in charge, has arranged three major field inspection trips to show typical examples of these features of California engineering development. These trips will follow the close of the convention at Tahoe and will extend through four days. They will be in general charge of Professor S. H. Beckett of the Division of Irrigation Investigations and Practice of the College of Agriculture, University of California, assisted by other members of the Society.

On Monday, June 28, the delegates will be the guests of the Pacific Gas and Electric Company during an inspection of the hydro-electric and irrigation systems of that company in Placer County, including Lake Spaulding, Drum Power House, and the foothill orchard areas about Auburn and neighboring towns. Leaving Sacramento early Tuesday morning, June 29, the entire party will be given apportunity for an all-day automobile trip over portions of the irrigated and reclaimed areas on both sides of Sacramento Valley, reaching as far north as Durham and Orland. Wednesday, June 30, the Sacramento and Stockton Chamber of Commerce will join the California Delta Farms Company and the Holland Land Company as hosts on a river trip from Sacramento to Stockton with frequent stops at points of especial interest to the visitors. Thursday, July 1, the party will drive by automobile through Modesto and Turlock Irrigation Districts, giving particular attention to irrigation, drainage by pumping, and farm electrification, the latter being one of the chief interests of Society members throughout the country.

Professor Fletcher has supplied MODERN IRRIGATION with the following tentative draft of the program for the meeting:

Preliminary Program Draft

Wednesday, June 23, Morning—Reception and registration of members and guests; Special meetings and conferences on Relation of Electricity to Agriculture and Land Clearing. Afternoon—General Session; Address by F. A. Wirt, President of the Society; Papers by J. B. Davidson, Iowa State College, in charge of National Farm Equipment Research, and J. D. Long, University of California. Evening—General Sessions of Farm Structures and Rural Electric Divisions. Papers by Miss Greta Gray, University of Nebraska; Max E. Cook, California Redwood Association; W. G. Kaiser, Portland Cement Association; A. W. Turner, Iowa State College, and W. G. Ward, Kansas Agricultural College.

Thursday, June 24, Morning—General Session; Papers by L. S. Wing, Engineer, California Farm Bureau Federation, and C. D. Kinsman, Division of Agricultural Engineering, U. S. Department of Agriculture. Afternoon—Steamboat trip around Lake Tahoe. Evening—General business session.

Friday, June 25, Morning—General Session. Papers by Professor F. J. Viehmeyer, Division of Irrigation Investigations and Practice, College of Agriculture, University of California; J. V. Mendenhall, President California Delta Farms Company; George Kreutzer, Director of Reclamation Economics, U. S. Bureau of Reclamation; and Major O. V. P. Stout, Division of Agricultural Engineering, U. S. Department of Agriculture, and Chairman Reclamation Division, American Society of Agricultural Engineers. Afternoon—General Sessions of Farm Power and Machinery and Reclamation Divisions, with papers by Professor C. O. Reed, Ohio State University; Professor E. J. Stirniman, Division of Agricultural Engineering, College of Agriculture, University of California; E. V. Collins, Iowa State College; Professor C. C. Johnson, Washington State Agricultural College, and others. Evening—Banquet.

Saturday, June 26, Morning—General Session, College Division, with Seminar in Teaching Methods, led by Professor C. O. Reed, Ohio State University; Discussion of Improvement in Research Projects, led by Professor M.

Afternoon—College Division Extension Program. Afternoon and Evening—Mountain trips and barbecue.

Monday, June 28, to Thursday, July 1—Inspection trips.

Large Attendance Assured

Preliminary information already in the hands of the Pacific Coast Section of the Society indicates that there will be a large attendance both at the main convention at Tahoe and on the inspection trips. The Pacific Coast Section includes in its membership men interested in every phase of agricultural engineering. The present officers of the Section are Frank Adams, Professor of Irrigation Investigations and Practice, College of Agriculture, University of California, chairman; Max E. Cook, California Redwood Association, Vice-Chairman; L. J. Fletcher, Associate Professor of Agricultural Engineering, College of Agriculture, University of California, Secretary-Treasurer. Professor H. A. Wadsworth, of the Division of Irrigation Investigations and Practice, College of Agriculture, is General Chairman of the Arrangements Committee, with particular features of the arrangements in charge of Professor S. H. Beckett, of the Division of Irrigation Investigations and Practice, College of Agriculture; Professors Charles F. Shaw and W. W. Weir, Division of Soil Technology, College of Agriculture; Professors Ben D. Moses, A. H. Hoffman, and E. J. Stirniman and J. D. Long and H. L. Belton, Division of Agricultural Engineering, College of Agriculture; W. W. McLaughlin and Major O. V. P. Stout, Division of Agricultural Engineering, U. S. Department of Agriculture; Max E. Cook, California Redwood Association; P. E. Holt and A. E. Loder, Caterpillar Tractor Company; Walter E. Packard, Land Department, Western States Life Insurance Company; David Weeks, Division of Rural Institutions, College of Agriculture, University of California; Leslie W. Symmes, San Francisco, and M. E. Klein, California Delta Farms, Stockton, and F. J. Southerland, Pacific Gas and Electric Company, San Francisco.

Improved Control on Draglines Found to Increase Capacity

WHAT effect does the factor of stiff control of draglines and shovels have on the efficiency of operation and the capacity of the machine? This is a question in which all operators of such machines are interested, and on account of this interest, considerable attention has been attracted to the results obtained in a recent test conducted in San Francisco, in which similar machines, with and without special equipment for easier clutch control, were tested side by side, engaged in the same sort of work.

J. P. Holland of San Francisco, builder of the skyline Boulevard, and a well-known contractor in the bay region, conducted the test. He operates three Northwest draglines, the oldest of which is not equipped with the "feather-touch" clutch control which was brought out a year ago by the Northwest Engineering Company. The other two machines are equipped with this device. Careful comparisons were made of the results obtained from the new machines and the old one, on the same contract and doing the same kind of work.

Mr. Holland reported that the machine equipped with the special clutch-control had done just twenty-five per cent more work than the machine that did not have this device. The manufacturers of the "feather-touch control" point to this as a direct and tangible result of easier operation, showing that ease of control plays a large part in the moving of materials. The assertion is made that the new machines, so equipped, eliminate eighty percent of the physical effort ordinarily required for shifting clutches.

The operation of the special control is explained as follows:

"Throwing the bucket, the common practice of fast operators, is more easily and more accurately accomplished. The bucket is instantly and easily retrieved from the ditch without any delays caused by fighting with stiff clutches. The result is, of course, more feet of ditch per day.

"The 'feather-touch' clutch control is a simple device which utilizes the power of the engine. Unlike a steam or air ram which necessarily must be all in or all out, the 'feather-touch' control retains the 'feel' of the bucket and also eliminates air tanks and compressors. By means of a small auxiliary drum on the main drum shaft and a band which is tightened on this drum by toggling connected with the operator's

lever, the power of the engine is utilized to throw the clutch.

"The clutch shifted, the band releases and thus does not burn out by dragging on the drum. Release of the clutch is positive, introducing a feature of absolute safety. The operator does not have to hold the lever in place while the machine is in operation.

"Pedals similar to those of a motor car, pedals that work in and out, are provided and the operator does not have to stand up to force them down but can manipulate them from a comfortable sitting posture. The arc of throw of the levers is also very short adding materially to the operating speed."

Knowledge Is Forests' Need

(*Continued from Page 17*)

use of our forest resources, but from devastation, it becomes more and more urgent that some definite action be taken to stop the ruthless destruction before the price which we must pay in the form of greatly increased denuded area and attendant economic losses and all the other losses which go with the loss of our National Forests become a national catastrophe.

To meet this situation, it is vitally and urgently necessary to arouse public opinion, through public interest and public knowledge. At the present time forest fires are the greatest single destroyer of forests. In addition to adopting strenuous measures to prevent and cut down the number of forest fires and vast acreage which is burned over each year public sentiment should be moulded to encourage the replanting of vast areas of burnt over land. According to the U. S. Department of Agriculture, the National Forests contain several millions of acres of forest land so severely burned that it cannot be restocked without planting. To restore this land to timber production is an immediate federal responsibility. Tree planting is most urgent on denuded watersheds from which water is obtained for power, irrigation or municipal use. The work already done by the Forest Service has established method, cost and the limit to the successful reforestation by artificial methods. This project can therefore be undertaken upon an assured basis of cost and results.

At the same time there is a responsibility upon every one who senses the seriousness of the situation and the necessity for action to do everything within his power to advance an understanding of the country's reforestation needs, and to assist practically in meeting those needs through every means at his command.

MANAGEMENT

URGES "APPLICATION SYSTEM" FOR CITRUS USE

By W. M. MERTZ

THERE ARE at this time no subjects of such general interest to the California farmer as those pertaining to irrigation. Due to the three dry winters just past our sources of irrigation water in 1925 were shorter than ever before in the history of Southern California. True, we did not suffer as we did in 1899 and 1900, but our gravity sources were considerably less during the past summer than was the case either of those dry years. The drilling of innumerable wells all over the southern part of the state and the forming of several artificial lakes by means of canyon dams so augmented the diminishing gravity flows that an irrigated acreage many times larger than that in 1900 has suffered very little from the shortage of rains during the past three seasons.

However, the continued lowering of the water levels of our wells in all our irrigated districts could not have gone on much longer without being felt in a real water shortage. When water is being pumped out of our underground basins faster than rains and snows in our mountains are replenishing it, it is simply a matter of time when a share of the wells will give out entirely. In many cases these will undoubtedly be those on the upper levels, which may drain out first, and it is here that one often finds the most profitable citrus property. It thus becomes of vital importance to all agricultural interests to use water more efficiently than in the past and especially is this true of the citrus grower who in many cases is already feeling the shortage and who, at least on the acre basis, has the greatest investment at stake.

Water Use Not Uniform

Citrus properties over the state are using very different total quantities of irrigation water. In some districts growers are raising good crops with only 18 to 24 inches of irrigation water per season. In other districts it is not uncommon to find uses of over 40 acre inches where the climate is no hotter or drying in summer, and where the trees are no larger, and strange as it may seem, in very many cases the crops taken from the heavily irrigated groves do not indicate any superiority due to the larger use of water. During the past three years, when the natural rainfall has been very short, those districts where larger volumes of irrigation water have been customarily used show, as a rule, better crops than those where the minimum irrigation water had been available. In fact, many of the orchards on heavy soil are carrying better crops now following the dry years than were harvested during years of normal rainfall, indicating that many of these heavy soils had been receiving too much water. On those receiving a minimum of irrigation water it soon became apparent that scanty rainfall and small applications of irrigation water ultimately reduced the available water for the orchard to a point where maximum production of satisfactory sized fruit was impossible.

MR. MERTZ' article, which is an excerpt from a paper delivered before the recent Citrus Institute, at San Bernardino, California, discusses a practical problem of real interest to irrigators. While it is addressed primarily to the grower of citrus fruits, it contains suggestions of value to all orchardists who irrigate on a fixed schedule.

The second part of Mr. Mertz' paper was devoted to general methods of increased efficiency in the application of irrigation water to the grove. It, too, is large with helpful suggestions for all irrigators using the furrow system of application. It will be presented in an early issue as a continuation of the accompanying aricle.

Allow me, first of all, to emphasize the need of all growers to curtail the use of water to the point of actual necessity in order that our underground basins may not become so depleted that the upper districts be caused to suffer heavy economic losses. By a study of your local moisture conditions throughout the season, many growers in the damper coastal districts as well as most growers on heavy soils, should find it possible to use less water and find in so doing that the great majority of their properties would actually improve from this reduction in water applied. This reduction in water will of necessity entail some additional study and labor, for when just enough water is applied great care must be exercised so to distribute it that portions of the orchard do not suffer for water.

The greater crops of better sized fruit which will ultimately result from more uniform water distribution should much more than offset the somewhat greater expenditure of labor in so distributing the water. In fact, the present crisis which is facing us is not an unmixed evil, for out of it already is growing a better understanding of the actual water needs of a citrus tree and bringing in improved systems for the distribution of water both as relates to main lines and in the orchard itself. In addition, public sentiment is being crystalized in favor of greater conservation of our water sources and will ultimately make Southern California more safe from a serious water shortage than she has ever been in the past.

Now I wish to go more in detail as to means of increasing the efficiency of irrigation water as it applies to our individual groves.

Favors "Application" Scheme

In the first place, I wish to emphasize the advantages that accrue from obtaining irrigation water "by application" as it is called in distinction from the still all too common "fixed schedule." By "application," I mean the system of obtaining your irrigation water by applying for it at such times as you actually need the water, while the "fixed schedule" system gives the grower no option in this matter and he is compelled to take his irrigation water on a certain date or—passing this date—he must wait until the period comes around, a matter of from three to five weeks.

A great amount of water can be saved by the application system during periods of cool weather or after late spring rains as well as from the fact that water users on heavy soils would not desire their water as frequently as the schedule

usually calls for and would go two or three weeks longer between runs if it were possible but would not dare to entirely skip a run and thereby double the intervals. This later saving during the hot summer months is often not a net saving in the water since under application the man on sandy open soils would be inclined to order water more frequently than the schedule would call for but in the long run it is a saving for both sets of growers since those on heavy soil save expense on water they did not use and which if used would have actually harmed their property, while those on sandy soil through the more frequent applications of water are enabled to bring their groves up in production to very much more than offset the some what greater cost of water applied.

Change in System Benefits

Since the Santa Ana Valley Irrigation Co. went over from schedule to the application system, the groves on heavy soil have notably improved both as to appearance and production for an immediate reduction in water used was apparent on these heavier soils. Although many of the sandier soils under service from this same water company used more frequent irrigations than in the past, this company has been able to supply water to its members on reasonable notice even these last two years when water has been shorter than in the early days of the schedule system.

At times of heavy use a limit is placed on the amount of water which can be used per acre per run, but as soon as this is completed the user can make arrangements to re-order should he feel the soaking insufficient to hold the soil moist for as long an interval as usual. This limit has never been lower than two acre inches which is as much as some companies give regularly on a fixed 30-day schedule. Now this mutual company furnishes water to some 17,000 acres and depends to quite an extent on pumps for its water during the fall months. No reservoirs are used in this system, so there appears to be no real reason why this application system of distributing irrigation water should work more easily with this company than with scores of other mutual companies in the citrus belt of California.

In fact, I cannot see why more mutual companies have not changed their methods of distributing water to their members long ago, for the growers who sit on directorates of all such companies have known for years that different soils require different amounts of water and at different time intervals if maximum results in the way of crops were to result. After all the evils which have been pointed out recently as starting in the use of too much water, I believe no large

KILLEFER

Methods of Irrigation

Accomplish These Beneficial Results:

Store water away in the soil DEEP=

Store it safe from wind, sun and runoff=

Leave the topsoil comparatively dry=

Permit wetting of uneven land=

Leave the ground easy to smooth off=

Get moisture quickly and cheaply into the root zone.

We have special irrigation tools for the panbuster and cultivator. Write for special literature and name of nearest dealer.

315 Montgomery Street, San Francisco

water company need fear that the change from schedule to application would immediately result in an increased use of water. Experience of those companies already having tested it shows the opposite to be true.

If the growers bunch their orders too much, start the pumps and during the rush double the cost of the water if necessary to cover expenses. A lesson or two is all that is necessary and they will string out in fairly good shape, although during excessive heat waves or dry winds it may be necessary to tax the entire system to the utmost, but who of us would not be more than willing to pay double if only water could be gotten when we badly need it?

My experience certainly causes me highly to indorse the application system both as it relates to the saving of water on lands which do not need it, and also from the fact that it puts in the hands of the grower himself the decision when he should irrigate his orchard and in most cases also allows him to gauge the amount he should apply without wasting it in runoff or too deep penetration at the upper end of his furrows.

Many of us, however, must be satisfied with the schedule system at least for the time being. Fortunately much of the land on certain of these systems is of rather uniform soil and although the schedule is a bit too long for the grower on very sandy soil as a whole it is doubtful if the interval could be changed to suit all growers any better as long as it remained a fixed schedule.

Is Cultivation a Fallacy?

(*Continued from Page 20*)

to be equally good growth in all of the tanks and no differences could be distinguished between the growth made by the plants in the tanks which had been cultivated and those which had not been disturbed.

Several tanks containing clay loam soil were irrigated on May 13, 1922, and the surface of the soil was undisturbed until October 26, 1922, during which time 32 pounds of water were lost through evaporation. The soil to a depth of 12 inches was removed and placed on canvas, thoroughly mixed and then replaced in the tanks. Vetch plants which had been grown in flats were planted in the tank. No water was applied to the soil and the tanks were protected from rains. The vetch plants matured, making a growth comparable to that of similar plants in the orchard. The crop was raised by means of water applied 167 days before planting.

The clay loam in these tanks had a relatively high moisture holding capacity

PIPE

Both USED and NEW--At a SAVING to YOU!

WHENEVER and wherever you need pipe of any size or dimension, Pacific can serve you and save you money, too. For general farm and irrigation purposes, Pacific Reconditioned Casing is a real bargain. Absolutely guaranteed. Every length straight and clean with new threads and couplings, each protected from damage in shipping by special steel protectors.

Every length rattle-tested and steam pressure-tested as proof against weakness; then dipped in a special non-tasting hot asphaltum which resists alkali and corrosion. This adds years to its life. Nowhere else in the West, except in the Pacific plant, can used pipe be so thoroughly reconditioned and then sold at such low prices.

and the plants were grown for the greater part of the time when the transpiration losses were low. Of course, it is obvious that such an experiment could not be carried on with soil of low moisture capacity or during a time when the atmospheric evaporating power is high. However, this does show clearly that there was a relatively large quantity of water left in the soil after long exposure to evaporation and that there were no differences in available moisture in the soils which had been cultivated and those which had not been cultivated.

Transpiration Major Factor

These experiments also show that the amount of water taken from the soil by plant transpiration is tremendously greater than that evaporated directly from the surface of the soil. Records obtained from tanks in which trees were growing and which were covered so that the losses of moisture were confined almost entirely to transpiration losses afforded an opportunity to compare further transpiration with evaporation.

In 1921, a three-year-old prune tree in a tank used 585 pounds of water between May 21 and Nov. 21, a period of six months, while a similar tank containing the same kind of soil but uncropped and cultivated, lost only 28 pounds within the same time. This same tree, from March 1, 1922, to Nov. 4, 1922, used 1,250 pounds of water, while the uncropped tank, which was irrigated Feb. 11, with 23 pounds of water, again lost only 28 pounds between this date and Nov. 4. The bare, uncultivated tank just mentioned contained Yolo loam, which had been packed in the tank in 1912 and had not been disturbed since that time.

In view of the results obtained from these experiments, some of which have been presented here, the question "What becomes of irrigation water?" might be answered by saying that, under usual California orchard conditions, by far the greater portion of the total amount which is applied to the soil occupied by roots remains in the soil until it is taken out by plants.

Engineering Society Celebrates

The San Francisco Society of Engineers gathered in the assembly hall of Islames Temple, Oakland, Friday evening, April 16th, celebrating their annual smoker. Song, dance and musical entertainers enlivened the event with specialty features, after which the members shared in a dinner. Co-operating with its Oakland members, 300 members of the Society were present.

You *Name the* Load
We *Make the* Pipe!

SINCE concrete pipe (as made by Bent) came into its own, engineers question no longer its striking advantages for a great variety of uses. *But*—a concrete pipe installation is either a mediocre or an eminently superior job of work, depending upon who fulfilled the contract.

Many trade names have become hall-marks of tradition, that serve as an unerring guide to discriminating buyers. Today the name "BENT" on a joint of Concrete Pipe marks it as a strictly finely made product. The same care and skill is exercised in its manufacture, and in the laying of the line, as though every future contract depended on *that* job meeting the fullest requirements of specifications—*and more.*

Let us give you a "concrete" demonstration of what we mean by "Bent" Service.

WITH THE WATER COMPANIES

Of Interest Expressly to Water Works Engineers, Superintendents and General Managers

HOW THE LABORATORY PROTECTS THE WATER USER

By DR. CARL WILSON

Director, Biological Laboratory, Los Angeles Bureau of Water Works and Supply

MODERN water works engineers have found that the laboratory is an important adjunct to their equipment; and, furthermore, that its usefulness is in large degree proportionate to the complexity of the system.

Los Angeles has a remarkable water supply—perhaps it would be correct to say that it is unique—in the wide range of biological conditions which are to be found over its catchment and impounding areas. The water-shed tributary to the Owens River aqueduct covers a region of more than 100 miles from north to south, and embraces the highest portion of the Sierra Nevada mountains as well as broad valleys, and even encroaches upon the edge of the desert. Tributary to the supply are more than 40 glacial lakes lying at elevations of from 8,000 to 11,500 feet above sea level, part of them snow-bound throughout the year.

The impounding system within a radius of 50 miles of Los Angeles has a number of large lakes under semi-tropical conditions, while between these two extremes can be found practically every intermediate type of environment. Since surface waters are profoundly influenced by their surroundings it is not surprising that Los Angeles has found itself face to face with numberless problems regarding control of growths which would affect the quality of its water supply.

Twelve years ago William Mulholland, Chief Engineer of the Los Angeles Bureau of Water Works and Supply, recognized the fact that comprehensive and long continued studies of the lakes and streams would be necessary in order to exercise the desired degree of control of such growths, and he accordingly inaugurated a laboratory division which was housed at Water Department headquarters where the engineering staff could keep in close touch with the work.

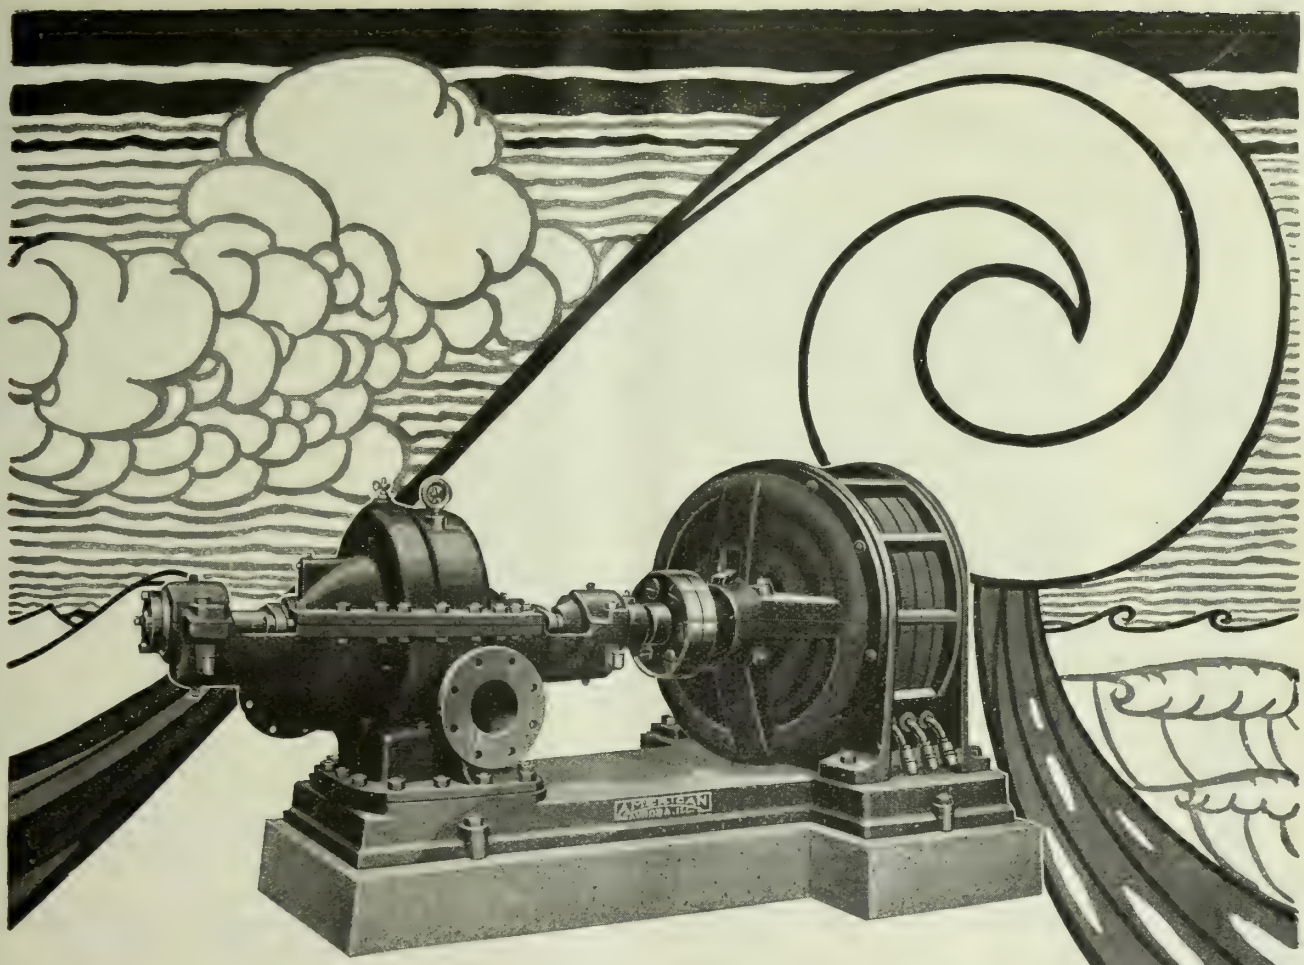
The first laboratory consisted of one small room in an out-of-the-way corner, but the equipment which was purchased at that time was carefully selected with the thought always in mind that it would form the nucleus of the complete laboratory which, it was expected, would be developed later. The laboratory outgrew its quarters twice, and has recently been installed in the new Water and Power building at 207 South Broadway. Here separate rooms are provided for the bacteriological work and for the chemical laboratory, while another room is used as an office and library.

In these completely equipped rooms a force of six workers, trained in the chemistry, bacteriology, and biology of domestic waters, are constantly at work on the diverse and interesting problems which beset the way of an engineer who attempts to furnish 165 million gallons of water per day to a great city.

The safety of a water supply is, of course, its paramount requirement, and consequently knowledge of the sanitary quality of the water as it goes to the consumer is the first concern of the laboratory. Wherever surface waters are used there is always the possibility which, however remote it may be, must be considered, that the water may be polluted at the last moment by a typhoid carrier, and to guard against this the latest practice is to sterilize such waters as they enter the distribution mains.

Miss Dorothy Brink, one of Dr. Wilson's assistants, peers through her microscope in a corner of the most completely equipped waterwork laboratory in the entire west. The laboratory is maintained in a scrupulously clean and sterile condition, as is suggested by the hospital-like appearance suggested in the photograph.

The Los Angeles system is so complex in its structure that six separate sterilization plants are needed in order to treat all the water. This means that a number of samples must be taken every day to be certain these plants are functioning properly, and that the water as it enters service is safe. The director of the laboratory has been made responsible for these plants, as well as



BACK of the name-plate **"AMERICAN"** stands fifty years of development in pump manufacture. This accounts for the universal acceptance of American Pumps as the ultimate in achievement wherever water is handled. No matter what your conditions are—an "American" will give you satisfaction.

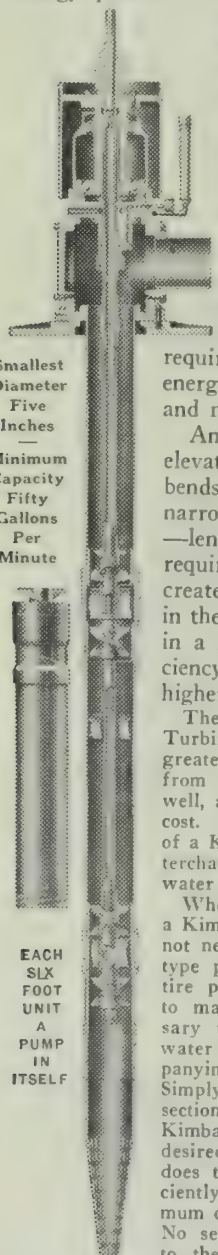
ITS NOT in the HEAD ITS IN THE PUMP!!!

The head transmits the power only. It's the pump in the well that does the work.

The shortest distance between two points is a straight line, and the least energy possible to move anything this distance is over this *direct* course. Any other route requires more energy.



Smallest Diameter Five Inches — Minimum Capacity Fifty Gallons Per Minute

EACH SIX FOOT UNIT A PUMP IN ITSELF

The Kimball pump is a *direct flow turbine.* It carries the water up in a direct, free, unobstructed, even diametered, straight channel, under an unchanging pressure; requiring the minimum energy, for the greatest and most efficient service.

Any other manner of elevating water — around bends and turns — thru narrow and wide passages —lengthens this distance, requires greater energy, creates uneven pressures in the pump;—and results in a lowered rate of efficiency and, consequently, higher cost.

The Kimball Direct Flow Turbine will deliver the greatest capacity of water from the minimum sized well, at the lowest operating cost. Every six-foot section of a Kimball pump is an interchangeable, complete water lifting pump, in itself.

When the water level in a Kimball well recedes, it is not necessary, as with other type pumps, to lift the entire pump out of the well to make the change necessary to reach the lowered water level, with the accompanying annoying delay. Simply add six-foot pumping sections to the top of the Kimball pump, adding on the desired length to be lowered, does the job. Quickly, efficiently, surely, — at a minimum cost in time and labor. No sending the pump back to the factory. The finest pump that money can BUY!

for any other chemical treatments which may be required at any point on the system.

It is interesting to note in passing that chlorine requirements at different points on the system, and at different times of the year, vary from one and a half pounds per million gallons to as high as five pounds per million gallons. The higher dosage is employed to destroy objectionable taste which is at times imparted to the water by growths of algae.

The Laboratory Routine

An average day's work in the bacteriological laboratory involves the examination of from 30 to 60 samples, taken from key stations so distributed over the system that perfect control of the water may be obtained. The City Health Department, under Dr. George Parrish, takes other samples regularly to check the work of the Water Department, and the State Board of Health, under R. F. Goudey, its sanitary engineer, takes other samples at frequent intervals. Thus the water consumer in Los Angeles has a triple assurance that the tap water is safe to drink at all times.

The bacteriological work on any water system is practically a routine matter, and of particular interest only to bacteriologists, so no further comment upon that branch will be made here, other than to state that the technique followed is that prescribed by the American Public Health Association.

Combatting Algae Growth

Growths of organisms other than bacteria, most of them microscopic in size, afford by far the most interesting problems which come to the laboratory and some of them have been solved by new and novel methods.

There are more than sixty varieties of plankton algae which are found in our waters during all or part of the year, and which occur in sufficient numbers to be of economic importance. With over thirty reservoirs, large and small, the labor of collecting plankton samples and actually counting the numbers of each type of organism present involves an immense amount of detail work, for such samples have to be taken twice a week at least.

Every water works operator knows how quickly such growths can develop and here in Southern California where the sun shines nearly every day in the year and water temperatures remain high for months at a time, it is no wonder that growths of algae are frequent and abundant.

Before control work was undertaken, mixed growths of Anabena, Aphanizomenon and Clathrocystis developed in Haiwee reservoir, an artificial lake 7½ miles long located in the desert, 200 miles north of Los Angeles, so abundantly that in the coves and bays windblown accumulations formed masses three inches in thickness, and it was possible to pick up solid blocks of this material just as one might pick up broken fragments of ice. No water works superintendent needs to be told what such a growth of algae can do to water.

Fortunately Haiwee reservoir is the first of a chain of lakes through all of which water has to pass before it reaches the consumer, and limited control measures in Haiwee, Fairmont and Dry Canyon reservoirs have been found sufficient to keep the water in acceptable condition, provided complete control is exercised in the remaining reservoirs nearer the city. Copper sulphate treatments are relied upon for the destruction of growths but the dosage used on the Los Angeles lakes is rather lighter than is generally recommended. As little as one part in ten millions is often used, while one part in three millions is about as high a dose as has been applied for general treatments. In conduits where it has been necessary to destroy an attached growth, doses of twenty parts per million have been used, but of course this was only possible where the treated waters could be wasted and the conduit subsequently flushed to waste before being restored to service.

Among the most interesting organisms which have caused trouble on the system are Beggiatoa, Crenothrix, and Plumatella. These have been conquered, but it is always possible, due to the physical character of the system, for Plumatella to appear again, and this organism is the one which is potentially the most objectionable because of the mechanical troubles it causes in the distribution system. Crenothrix flourishes only in iron-bearing water, and Beggiatoa only where sulphur is available. Both iron and hydrogen sulphide are absent from practically all of the Los Angeles supply, being found only in small quantities of water pumped from certain well groups, so neither of these organisms has given long continued trouble, but they are always unwelcome visitors.

Mineral Analyses Frequent

A great many complete mineral analyses of waters from all parts of the system are analyzed every year, and partial analyses covering a few constituents are made in great numbers. The chemical laboratory is also called upon, from time to time, to examine materials used in dam construction, as well as to investigate the origin of seepage waters. During the coming summer a new line of investigation is planned to determine whether algae may be controlled by ar-

tificial adjustments of hydrogen ion concentration in the reservoirs. Research work along other lines is contemplated, but in the past limited room and personnel made such studies impossible.

In conclusion it may be said that the laboratory sometimes solves problems which otherwise are very stubborn. Several years ago stickleback appeared in immense numbers in one of the terminal reservoirs, and these fish, when less than half an inch in length, went through the screens and to the consumer's tap. Naturally complaints were numerous and vociferous and something had to be done, but what? Screens were ineffective and all other measures which were tried proved useless. The laboratory discovered that stickleback in a mountain stream fifty miles away were dying from a flatworm parasite which was known to affect only five species of fish, and to be unable to live in the body of a warm blooded animal. This parasite was promptly grafted upon the stickleback in the reservoir, and a few weeks later all the annoysome fish had been killed. They have never reappeared and probably will not, as they are known to be absent from the waters feeding this chain of lakes.

Sugar Cane Irrigation Shown Profitable

Continuation of the co-operative investigations of the irrigation of sugar cane by the Department of Agriculture in 1925 confirms the conclusion based on the work of previous years that such irrigation is profitable.

The experiments are conducted by the Division of Agricultural Engineering of the Bureau of Public Roads in cooperation with the Columbia Sugar Co., near Franklin, La. Comparing irrigated with unirrigated sugar cane, an average increase in yield of 3 tons per acre and an estimated increase of 480 pounds of sugar recovered per acre are the results obtained in 1925. The season began with a severe drought and ended with a very wet fall. The 1924 season was an unusually dry one and an increased yield of 5.6 tons per acre was obtained. The two preceding seasons were so wet that no irrigation was necessary.

It is believed that the profits due to irrigation in dry years will more than offset the cost of maintaining irrigation facilities in wet years when no irrigation is necessary.

The same pumping plant was used to irrigate both cane and rice. The economy of this system is apparent where rice may profitably be raised on the same plantation as sugar cane. The amount of water that was needed was diverted from the rice ditch and forced to the high point of the cane field and allowed to run down the furrows and across each succeeding headland.

The A. B. C. of Corrosion Prevention

Q: What causes corrosion? A: Directly or indirectly the contact with metal of moisture, acids and alkalies such as commonly found in the air or the soil. All authorities agree on that.

Q: What prevents it most effectively? A: A Coating of metal surfaces that permanently inhibits such contact.

Biturine Enamel

"arch enemy of corrosion"

has a 20-year marine record and a 15-year underground record for this purpose, reducing upkeep to practically zero.

Further comprehensive Data on Corrosion Prevention, including Working Specifications, are compiled in our book on "Pipe Protection". Yours, if you write for it.

RECLAMATION

DR. WORK PRESCRIBES H_2O FOR SOUTHWEST'S ILLS

APPEARING on April 26 before an audience that filled Los Angeles' largest dining hall to overflowing, Hubert Work, Secretary of the Interior, gave the Colorado River Boulder Dam project the most outspoken endorsement that it has ever received from an administration leader. Secretary Work and Elwood Mead, Commissioner of Reclamation, were present as the guests of the Los Angeles City Club and Chamber of Commerce, but the audience that heard the Secretary's remarks was broadly representative of official, business and agricultural leadership throughout Southern California.

Arthur Bent, himself an outstanding figure in hydraulic development, called the meeting to order as president of the Los Angeles commercial body, and introduced George Dunlop, president of the City Club, as presiding officer. In commenting on the purpose of the meeting, Mr. Bent complimented the leaders of the Interior Department for their efforts to free the Colorado River from political considerations, and to study it as a purely engineering and economic problem.

Dr. Work's Specific

Mr. Dunlop presented Dr. Work, expressing the hope that he was about to write the largest and wettest prescription of his many years of medical practice, and the Secretary fulfilled expectations. His remarks were delivered under the handicap of sickness, but were nevertheless eagerly listened to, and were big with meaning for his attentive audience.

In part, Secretary Work's remarks were as follows:

"This tremendous engineering task (the proposed developments of the lower Colorado River) if carried out, will rescue from menace the homes of 60,000 people, and farms valued at more than $60,000,000. It should, when completed, more than double the reclaimed area in a section of the country where climate contributes the greatest value to irrigated crops. This agricultural development will be supplemented by an industrial development only second in importance, due to the creation of a great volume of cheap power. It offers certainty and security of an increased water supply to two great cities of the arid region, Denver, east of the Rockies, and Los Angeles, west of the Coast Range, both outside the watershed of this river and both dependent on it for their future growth.

"The pending Colorado River compact should make possible a just division of the river waters between the upper and lower States, and bring to an end a threatened and costly interstate rivalry. The proposed compact opens the way, too, for the settlement of an international problem, along lines which will safeguard the use of this stream for our own people and work no injustice to our Mexican neighbors.

World's Greatest Project

"These potential benefits are enough to make this a development of great national interest and importance. But, also, there are still other unique and significant features which are epochal and far-reaching. In its engineering phases, the proposed project will be the greatest work of its kind in the world, the highest dam, the costliest canal and one of the largest developments of hydroelectric power,—all intended to contribute to human welfare and the creation of new wealth throughout the Colorado basin and tributary country.

"The necessity for an early settlement of the respective rights of the different States and two nations in this river, and in the carrying out of the proposed development on the lower portion of the stream, is vital. We have come West to see the location where the principal works are to be built, and meet the people primarily interested, whose future progress is so largely dependent on this development.

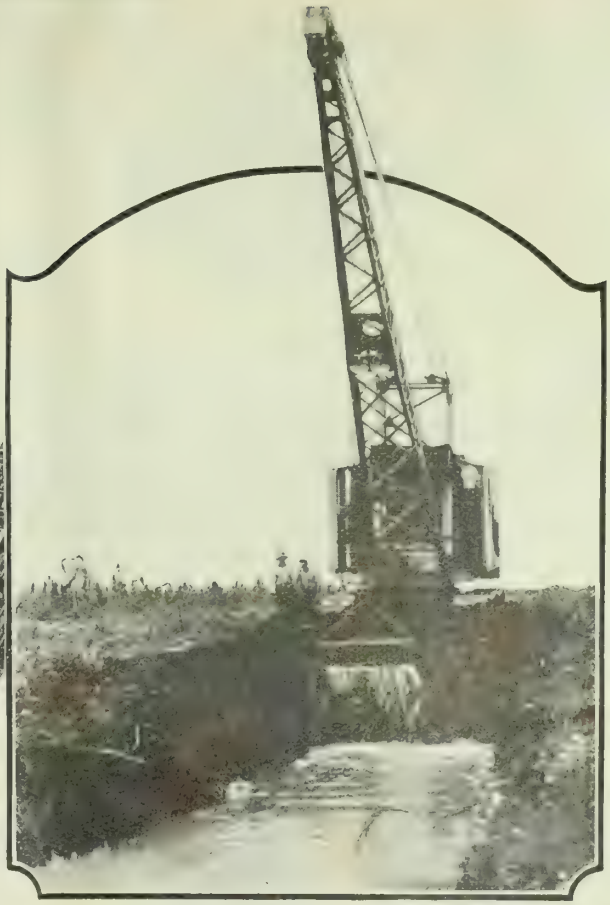
"Prominently before the Congress now is the matter of the development of the Colorado River in its entirety. Fortunately, Northern and Southern California have agreed to further the dam project, which is of first importance to you. All of the basin States, with one exception, are in accord. The Administration agrees with these States as to the importance of developing this potential national asset, and is hopeful that permanent and satisfactory adjustments for river use between the several States and our Mexican neighbors can be established for all time.

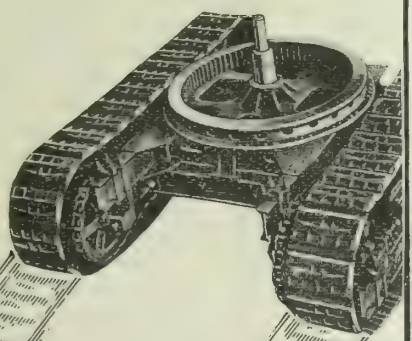
Too Big for Private Hands

"I am opposed to government ownership or operation of any public activity that is within the compass of private citizens. For five years I have been directing government services under a mandate to 'centralize authority and decentralize responsibility.' But conflicting, diversified and far-flung interests are involved in the Colorado River development, that compel a closely knit organization to correlate them.

"No individual or corporate entity licensed for totally different and diversified purposes, could be found to guard one interest and equally protect the rights of others.

"The citizens' right of appeal is their due against unfair advantage by monopolistic utilities, but no local authority can compel services from a company not included in their charter or for which they are not paid to perform. States' rights for civil protection and local industrial development is fundamentally sound in theory and an essential to a proper functioning of the Federal Government. Yet, changing conditions have waged an economic, social, industrial and governmental revolution in this country in the past ten years. The World War broke down precedents and practices and, because of our readjustments, we would now seem to appear as a new nation. Larger corporations and mergers are a necessity because of these changed conditions and men's views, too, must change to meet them. But corporations are not geared to operate unrelated businesses or to bring about interstate and international comity, and mergers have been compelled which contemplate consolidations of related business to cheapen their service. Many, perhaps, are not pleased with the change,





No other crawler like this

GETTING your dragline from where it is to where you want it is often a big part of the problem. After digging, moving is the best thing that a Northwest does.

There is no travel base like the Northwest patented crawler base. It is the only one that maintains full traction while turning as well as while going straight ahead. The operator never blocks one crawler of a Northwest to turn—he simply slows it down. This means the elimination of those terrific side strains that cause the crawler to roll off and delay operations.

This patented Northwest steering device coupled with the other advantages of the Northwest make it ideal for irrigation work. The Northwest is controlled entirely from the cab and steers without lining the cab up with the crawlers.

Investigate the Northwest—

It's the most mobile dragline on the m rket.

Drainage and Flood Control Engineering
By G. W. PICKELS
Assistant Professor of Drainage Engineering, University of Illinois

THIS BOOK COVERS ALL PHASES OF THE DRAINAGE ENGINEER'S WORK FROM THE DRAINAGE OF SMALL AREAS OF FARM LAND BY TILE UNDERDRAINS TO THE RECLAMATION OF LARGE AREAS BY FLOOD PROTECTION, BY DRAINAGE THROUGH OPEN DITCHES AND BY PUMPING.

450 pages, 6x9, Illustrated. $4.00 Net

The marked advance in drainage practice in recent years is emphasized throughout. The sciences of hydrology, hydraulics and soil physics—particularly the results of recent researches—are satisfactorily covered from the specialized viewpoint of the drainage and flood-control engineer.

The book gives a comprehensive and well-balanced picture of drainage practice as carried on today. The economic justification of drainage and flood-control projects is set forth clearly. The legal organization of drainage districts, the essentials of drainage law, and the spreading of assessments make up a final valuable chapter.

but it is here, and a new epoch in the nation's history is being written. . . . .

INERTIA CAUSES DELAY

"Though the Lower Colorado River development has been under consideration by Congress for two generations, nothing tangible, constructive, or lasting has ever been accomplished. Through legislative procedure the bill came to the Department of the Interior for comment relating to possible policy and suggestions for administration.

"For the first time, concrete, specific recommendations, comprehending the diversified and coordinated use of the river, were made to Congress by the present administration of the Interior Department, which reported frankly, carefully and sympathetically, on this bill. Proposals by the Department for certain changes in the bill were immediately approved by its authors and today, as you know, the measure is awaiting definite action by Congress. The Interior Department is openly supporting the general principles of the bill, but delay in the enactment of this measure is being caused by the inertia which all great undertakings encounter, and the necessity for adjusting rival and conflicting views.

"Some progress has been made in negotiations with Mexico, looking to the safeguarding of the river rights of that country in relation to our own, but no authority to obligate this Government in any co-operative manner can, of course, be exercised without action by Congress, and Congress is to adjourn very shortly, possibly without action on this Boulder Dam project.

"My proposal, that the funds needed for this entire development be obtained from the sale of Government bonds, was made because it is believed that enough revenue can be obtained from the sale of water for irrigation and domestic use, and the sale of power, to make this a solvent undertaking, paying interest on all the money expended and returning the principal within a reasonable time. To finance the enterprise in this way would remove a serious objection from taxpayers in other parts of the country, who can see little reason for advancing funds out of the national Treasury as a temporary expedient, to be replaced by them in the form of taxes, when it may be possible to make the project a self-sustaining one without disturbance in the fiscal operations of the Government. . . . .

WEST MUST REMOVE DOUBTS

"Early action should be directed to removing the misgivings of doubters as to your necessity for more water for irrigation and domestic uses, and it should be shown that there is a sufficient

demand from industries for the power that can be generated.

"Should Congress fail to instruct the Secretary of the Interior to secure contracts for the sale of power and water from the Colorado River, to potential consumers, he proposes to initiate such procedure himself and, if possible, have formulated something tangible to present to Congress when it meets next winter. These proposals will have to be of a general character, because work of this magnitude will require from five to ten years to complete, and the proposals will have to be for a service which does not begin now but at least five years in the future. This fact, however, is not an argument for delay. On the contrary, it is the most potent argument for early authorization to construct. . . . .

"The dam, regarded solely for manufacturing, and sale of power alone, would be a departure from established Government policy, without justification in precedent. Protection against floods, adjudication of rights to the use of waters in international streams, protection of watersheds and navigable streams, are recognized functions of the Government. Reclaiming land by irrigation for agriculture, anticipating annually recurring drouth peculiar to arid regions, has been accepted as Government practice. All of these will be touched or determined by the construction of the proposed Boulder dam, which, in itself, however, is of less moment than the ratification of a satisfactory river compact between States, the United States, and Mexico.

"Destruction from floods and probable drouth are local problems. Production of power for light and manufacture are constructive suggestions. Compacts to regulate use of water have to do with comity between neighbors having separate rights to a common opportunity provided by nature and are largely moral in their relations, but none the less compelling in their claims for consideration.

"No structures heretofore built for any of the purposes indicated promised a cash return, except reclamation. The proposed Boulder Dam bill promises to utilize the water it will store, to amortize its costs, and even now some 25 applications from private parties are pending for permits to build power plants on the higher reaches of the Colorado River.

Private Developments Encouraged

"It is my belief that as soon as the Boulder Dam legislation has been approved by Congress, the applications for private power developments should have immediate consideration. There does not seem to be any danger that the pow-

(*Continued on Page 43*)

For Cleanout -- Maintenance -- New Ditches

There's a Bay City for Every Job

BAY CITY Land Dredges span the ditch, can dig any desired slope, and dump waste on both banks. BAY CITIES leave clean, wide berms, and can work up or down streams. One trip over the ditch is enough. The Shovel Type Dipper handles hard material in which other types of buckets cannot make a good showing.

At left—One yard BAY CITY Dredge digging and cleaning ditches in Florida Citrus Groves.

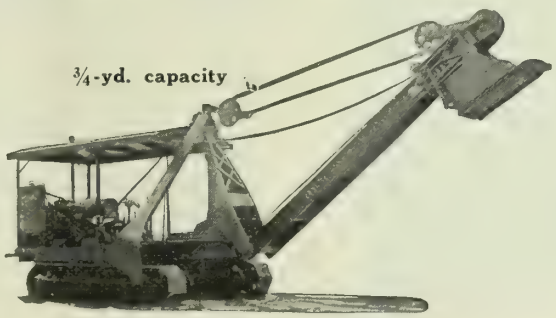
BAY CITY Land Dipper Dredges are built to fit the job. Walking, Crawler, Track or Floating mounting. Easily dismantled, transported and assembled. Capacities ½ to 1½ cubic yards. Oil engine or electric operation.

FOR SMALLER DITCHES — OR PIPE LINE TRENCHES

The BAY CITY 16-B convertible Excavator will handle a wide range of work. Operates Dragline, Trench Shovel, Clamshell or Skimmer. All steel. Shipped assembled. Digs any width or depth up to 20 feet.

STEEL CONSTRUCTION

¾-yd. capacity



FULL CRAWLER MOUNTING

or—Model 4 Excavator

BAY CITY Model 4 is a small low-priced convertible, one-man operated Excavator. Fills the gap between hand labor and high priced equipment. Capacity 20 to 40 cubic yards per hour. Gasoline or electric power. A Real Digger economically designed for the small job. Also operates shovel, and clamshell.

WHO'S *WHO* AND WHO'S *WHERE*

IN THE WORLD OF HYDRAULICS

Personal Notes and Impersonal Observations About Men You Know

George W. P. Hunt, now serving his fifth term as Governor of Arizona, has announced that he will be a candidate for re-election. Governor Hunt has been prominent in his activities relating to the development of the Colorado River, and is counted one of the most powerful opponents of the ratification of the interstate compact.

General Lansing H. Beach, former chief of engineers of the U. S. Army, General W. H. Langfitt, former chief of engineers in France, and A. J. Wylie, of Boise, Idaho, former reclamation service engineer, have been appointed as a board of consulting engineers to pass upon the plans and specifications for the Coolidge Dam at San Carlos, Arizona.

C. T. Pease, formerly of the U. S. Reclamation Service and regarded as one of the foremost engineers in government service, died recently at his home in Denver, Colorado. For some time he was project manager of the Uncompahgre Project in Colorado, and was a member of the advisory board appointed to report on the Columbia Basin project.

A. M. Van Norman, assistant to William Mulholland, chief engineer for the Los Angeles Bureau of Water Works and Supply, late in April made an inspection tour of the work being done by the city on its Colorado River aqueduct and the filtration canal work going on near Blythe, California. The city is installing pumps here to test the flow of water through the gravel and determine the possibilities of getting clear water from this source.

Officials of Bellingham, Washington, including Mayor John A. Kellogg, City Engineer J. C. Hills and City Water Superintendent J. B. McMillan, visited several large cities of the northwest in April in conference with consulting engineers on water problems of their municipality. The city is seeking a suitable engineer to be retained by the water department to survey and draw plans for an enlarged and improved system to care for the potential demands of a population of 200,000.

Well known irrigation men of Washington were in conference with officers of the Walla Walla Irrigation Company in April on its hearings before the state department of hydraulics, involving its rights to water from the Walla Walla River and tributaries. Charles J. Bartholet is the referee in the proceedings; Fred J. Cunningham of Spokane represented the claims of the company, and Marvin Chase, former superintendent of hydraulics and L. O. Jaynes, land expert, from Olympia, were interested.

Representatives of the Yakima, Kittitas, Kennewick and Yakima-Benton (Washington) irrigation districts are to unite in a league for the promotion of their common interests, and the formulation of a development policy upon which all can agree, if plans laid in April come to fruition. The four districts were represented in a meeting at Yakima April 17 when it was decided that one man from each of the districts will be appointed to serve with O. C. Soots, representing the Yakima Chamber of Commerce, as a fifth member.

F. A. Reid, president of the Salt River Valley (Ariz.) Water Users Association, was returned to that office for a term of two years in an election in April, when the shareholders of the association gave him a majority of approximately two to one over his opponent, Thomas Maddock. C. S. Stewart was re-elected without opposition as vice-president of the association. Andreas Jepson, member of the board of governors, was defeated for re-election by John Dobson. George Day was elected to the council in place of L. E. Graham. The council and board of governors are solidly in support of the administration policies of President Reid as the result of the election.

The city and county of San Francisco and the cities of the San Francisco peninsula are negotiating for a basis of cooperation which will mutually assist in the solution of their water problems. A committee representative of both interests has been appointed under the auspices of the League of California Municipalities to study the water situation and to suggest a form of organization and plan of action which would make it possible to meet the needs of the whole peninsula in one project. Supervisors Warren Shannon and M. F. Kent and City Attorney J. J. O'Toole of San Francisco, Professor C. D. Marx, of Palo Alto, and O. F. Weissergerber of San Mateo, comprise the committee.

Dr. George P. Clements, director of the agricultural department of the Los Angeles Chamber of Commerce, was host at the University Club, Los Angeles, on May 3, to a group of representative conservation and forestry men of the southwest, who gathered to honor Stuart B. Show, recently appointed California District Forester, U. S. Forest Service, and to discuss with men of the forest service some of the urgent conservation problems facing California. Mr. Show has recently succeeded Paul G. Redington as District Forester, and the occasion was his first official visit to the southern part of the state since his advent to that office. Among those who met at the invitation of Dr. Clements were: Judge Harold Curzon, forest enthusiast and conservation "evangelist;" George H. Cecil, supervisor of the Angeles National Forest; S. B. Morris, superintendent of the Pasadena City Water Department; Burlingame Johnson, chairman of the conservation committee of the California State Senate; C. E. Jordan, district forest inspector, San Francisco; J. E. Elliott, supervisor of the Cleveland National Forest; Everett Stanford, deputy county forester of Los Angeles County; Robert Deering, assistant district forester, San Francisco; Samuel Borden, supervisor of the San Bernardino national forest; William Mendenhall, supervisor of the Santa Barbara national forest; E. I. Kotok, inspector of California forests, San Francisco; J. M. Paige, secretary, Pomona Chamber of Commerce; L. S. Gilman, President, Angeles Forest Protective Association; Douglas G. McPhee, Editor of MODERN IRRIGATION, and the guest of honor, Stuart B. Show.

Dr. Work Prescribes for Southwest

(*Continued from Page 41*)

er market will be oversupplied. On the contrary, cheap power will help to open up new mines, promote the building of new railroads, and multiply industries. Your State laws would be ample protection to producing companies and their patrons alike, but it is not clear that licensees could be compelled by law or regulation to guard an international agreement for water storage, stream equation or division, give equal consideration to the dominant uses of agriculture, domestic water and flood control —in short, of this natural asset,—when the ever-present necessity for financial returns on investments would press.

"I must view this vital matter, in the Department of the Interior, from the standpoint of a public servant. The tenets of this measure can not be written to suit every one interested. The Colorado River compact is being resisted by a State that could profit by this comprehensive development. Maneuvering for individual or corporate advantage is being resorted to by those speculating in hopes, but it is confusing the main issue. If there are among you individuals who for personal, partisan or political advantage are embarrassing this project, they should be excluded from your councils.

"I have submitted proposals to Congress, intended to show how this development may be effected by the government on commercial lines, the revenue to repay the costs with interest, in a reasonable time.

"If an organized corporation, competent and willing to develop this project in its several ramifications, will come forward and submit a contract to build these structures and place their operation under such control of the government as will protect the many and diversified interests involved, the Secretary of the Interior will recommend to Congress that such proposition be sympathetically entertained."

Dam Named for Senator Gibson

A tribute to the memory of former Senator Paris Gibson of Montana will be paid to him by designating as "Gibson Dam" the proposed storage dam on the Sun River irrigation project in Montana. The tentative plans for the new dam, which will bear the Senator's name, call for a masonry structure more than 200 feet in height, with a crest length of 820 feet and a volume of 195,000 cubic yards. The area of the reservoir behind the dam will amount to 1,360 acres, with a capacity of 105,000 acre-feet.

DIGGING—CLEANING CANALS
AT LOW COST

THE NEW RUTH WITH ITS CONTINUOUS FLOW OF DIRT will dig or clean canals and trenches at a minimum cost per cubic yard or lineal foot heretofore considered impossible. The Ruth cuts continuous, even banks and smooth bottoms. Working successfully in marshy or dry ground, or canals full of water. The Ruth positively cleans the canal of all muck, sand, small willows, tules and water grasses.

Send for Bulletin No. 8—it illustrates the New Ruth Dredger; type and size of canals it will dig or clean; gives specifications, operating costs and maximum capacities.

LEGAL *and* JUDICIAL

A DEPARTMENT CONDUCTED BY HANKINS & HANKINS

Finality of Order of Board of Directors

An order of a board of directors of an irrigation district in excluding lands is held to have force of judgment.

The Supreme Court of Colorado, in the case of Yellow Jacket Irrigation District v. Pleasant Valley Ranch Co., 243 Pac. 635 (Jan. 18, 1926) held, on the question of the finality of an order of the Board of Directors excluding certain lands from the district, "That the Board of Directors was a tribunal whose decision has the force of a judgment." The Court cites in support of the statement the case of Wilder v. Irrigation District, 135 Pac. 461, where the tribunal under consideration was the board of County Commissioners, but where, it claimed, the analogy was complete.

What Constitutes Prescriptive Right?

To establish a prescriptive right to the use of a ditch something more than mere permissive use must be shown.

In the case of Abrams v. Colwell, 243 Pac. 615 (Colo. Feb. 1st, 1926,) the plaintiff brings a suit to quiet her title to an easement consisting of a right to conduct water across the lands of defendant through pipe line and canal, and introduces evidence of an executed parole license and a claim of right for more than 20 years. The defendant claimed that the use was permissive only and could be revoked at any time.

In supporting the judgment in favor of the plaintiff the court stated "It is true that, in order to establish a prescriptive right, something more than mere permissive use must be shown, but in the instant case much more than permissive use is shown, and the evidence relative to the prescriptive right, considered in connection with the evidence of an executed parole license is ample to sustain the findings and decree."

Rights-of-Way and Ways of Necessity

A right of way for a ditch to irrigate lands is not a "way of necessity".

In the action of Alcorn v. Reading, 243 Pac. Rep. 922, (Feb. 8th, 1926), the Supreme Court of Utah held that the common law rule as to a "way of necessity" arising where a man purchases land accessible only over the land of the vendor . . . he shall have a way of necessity over the land which gives access to his purchase, did not apply to the matter of an irrigation ditch.

In this case plaintiff was the owner of certain lots of land across which, at one time, had been constructed an irrigation ditch. Defendant had purchased certain other lots from the same grantor as plaintiff, and went upon the lands of plaintiff for the purpose of cleaning out and using this ditch. Neither the ditch nor the water rights were referred to in the deeds of plaintiff or defendant although the ditch was easily to be seen at the time that both plaintiff and defendant obtained their lands.

In denying the defendant any relief under the theory of "way of necessity" the court states:

"The common law doctrine relating to ways of necessity, undoubtedly was founded upon an absolute necessity of the case. Without such rule there was no means by which the right could be enforced against the consent of the owner. No right of condemnation was allowed if the right sought was for a private purpose. The same rule exists today in the jurisdiction in the case of ways of necessity, for ingress and egress across the lands of another. A different rule applies in this state in the case of canals and ditches and other means of conveying water for beneficial purposes. These are declared to be public uses by statutory provisions (Laws of Utah). The right of condemnation for such purposes is thereby allowed without regard to whether the right is sought by the public, or by a private individual. It follows, therefore, that in this jurisdiction where a right of way for an irrigation ditch can be obtained under the statute of eminent domain, the right cannot be obtained on the theory that it is a way of necessity enforceable under the rules of the common law . . ."

The court further says: "We base our decision, however, upon the proposition that an easement for an irrigation ditch upon the theory of an implied reservation does not exist in this state, however necessary the easement may be, for the reason that the statute of eminent domain provides a complete remedy by proceedings in condemnation."

Limitation of District Warrants

Irrigation district warrants out-law in four years.

A very interesting decision was rendered by the District Court of Appeal of California, Third District, in the case of People vs. Honey Lake Valley Irrigation District, et al., Vol. 59 Cal. App. Dec., page 830 (April 7th, 1926) wherein various points arising through the issuance of Irrigation District warrants under the California Irrigation District Act were passed upon.

The case arose on a petition for the dissolution of the irrigation district and the intervention of certain warrant holders asking for judgment against the district for the amount of their warrants. The District pleads the four-year statute of limitations. In its decision, holding the warrants and claims to be outlawed, the Appellate Court held:

(a) District warrants without a due date are payable on demand and the statute of limitations commences to run from the date of the warrant.

(b) District warrants are general obligations of the Irrigation District and the rule that the statute of limitations does not commence to run until funds are available where warrants are payable out of a specia fund, does not apply.

(c) The proper remedy of the warran holders was to bring a suit in mandamus either against the district, or if the distric could not function, then against the boar of supervisors, to compel the levy of a assessment to pay the warrants.

(d) The warrant holders could hav avoided the bar of the statute of limitation by converting their claims into judgments

What Is A Spring?

"Spring," as water source, defined b Supreme Court of California.

In the case of Harrison, et al. v Chaboya, et al. ———Cal. Dec.——— (April 22, 1926) the Supreme Cou of California defines the meaning of th word "Spring" as applied to a sourc of water supply.

The "Spring" consisted of a woode box sunk in a marshy place and radia ing troughs leading to this box. Lat a second box was sunk about forty fe away and the two boxes connected b a pipe line.

The controversy arose over the que tion of whether the deed in using th

words "all the water issuing from our spring . . . located on the west end of a certain tract of land" conveyed the right to the use of the water from the swampy area, or was limited to the water in the first box.

The Supreme Court stated: "We are of the opinion . . . that the term 'spring' in its common acceptation, at least in California, is a term which, in general usage, has been applied to damp, marshy or boggy area, usually of small but definite extent, wherein underground waters from a larger tract of land find their way to the surface thereof and make their presence known either by a definite outflow or by the surface presenting such a quantity thereof as will render practicable their assembling in such receptacles as those described in the record herein. . . .We incline to the opinion . . . the testimony . . . would constitute a sufficient basis for its (trial court) finding that the waters issuing from the earth at both of the indicated points were waters which had a single source, and hence were embraced within the terms of the original grant of the easement . . ."

Don't Forget Ground Water

(Continued from Page 16)

seems simple to put down a well, and sites for wells, in most instances, have been little guided by scientific study. In fact, in the majority of instances where advice has been solicited as to well location, sites were largely selected, until the past decade, by a process that had no relation to the natural sciences but rather the super-natural. This process is known as "water witching" and, even though the process has been thoroughly discredited, there are still many localities where the advice of a "diviner" is solicited.

It should be evident to all that the opinion of a geologist, in our present state of knowledge, should be more valuable than that of one who professes to have the gift of divination. Geologists, in selecting and recommending sites for development, are liable to miscalculation and failure if their broad training and experience has been deficient in the specific application of geologic processes and phenomena to the occurrence, distribution, and movement of ground-water. However, the greatest error the geologist falls into is that he overlooks the necessary hydraulic and hydrographic elements of this problem. His training is lacking along this line. His geologic conclusions as to the presence of an aquifer which has all the characteristics which would enable it to store and yield abundant water may be correct, but the development may be a failure because

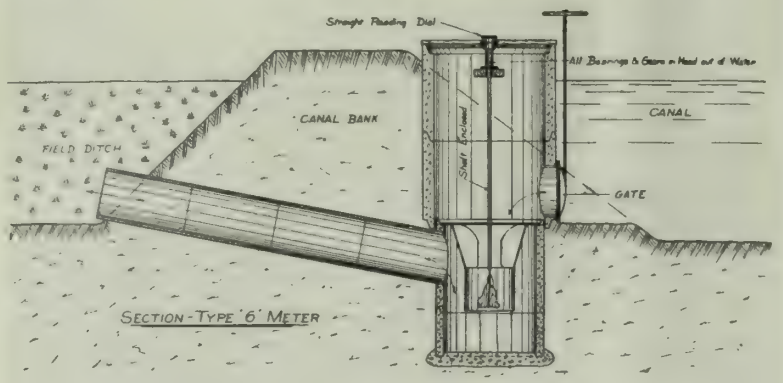
The RELIANCE METER



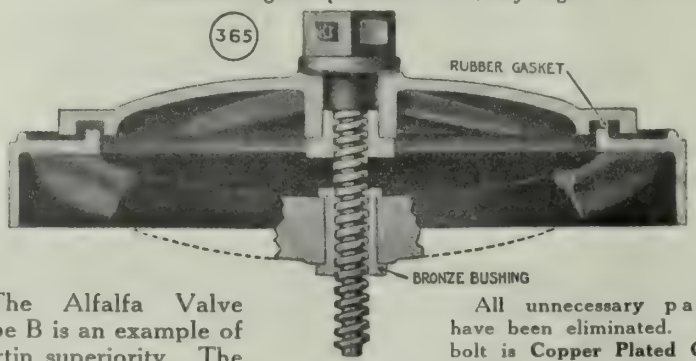
THE "Type 6" Reliance Irrigation Meter offers you standardized permanent construction at a very low first cost. Their sustained efficiency with a minimum of upkeep has been proven by 12 years usage. Cut shows installation of the 4 sec. ft. size in 24 and 30-inch concrete pipe. This is the standard type of setting adopted by many irrigation districts in Texas and elsewhere who are now equipping all their deliveries with this device. The "Type 6" meter is furnished in sizes ranging from ½ up to 16 sec. ft.

For further information and prices write—

RANDALL CONTROL & HYDROMETRIC CORP.
1014 E. Ninth St., Los Angeles, Calif.

Martin Alfalfa Valve, Type B

THE Martin line of Irrigation Appliances is the proud achievement of an organization of engineers and irrigation specialists who have worked out ranchers' irrigation problems from every angle.



The Alfalfa Valve Type B is an example of Martin superiority. The solid flange encircling the concrete pipe protects the pipe from breakage and forms the best method of permanently cementing the valve to the pipe.

We manufacture the original line of Irrigation Appliances. Outlet Valves and Cut-off Gates for the definite division of water over the field from Concrete Pipe Lines.

All unnecessary parts have been eliminated. The bolt is **Copper Plated Cold Rolled Steel, Square Thread, Machine Cut** and is of sufficient length to permit full opening without removing it and the lid. On 16-inch and larger sizes a stop nut is placed at the lower end of bolt to prevent removal.

of the lack of external water to supply and recharge the aquifer.

The engineer is at a great disadvantage unless he has sufficient geologic training to be able to ascertain the origin and history of rock formations, to interpret geologic structure, and understand the modifying effect they have upon the hydraulic elements of his problem. Therefore we believe the function of "divining" should rightfully and most successfully be limited to the ground-water hydrologist.

This brings us to the question of what knowledge one must possess in order to qualify in ground-water hydrology. The experience of the writer, together with professional contacts with engineers and geologists engaged upon like problems, have shown him that the broad fundamental training of either alone is inadequate to an understanding of the principles involved in the science of ground-water hydrology.

The science of geology contributes a knowledge of the geologic processes through which rock formations (and included in this term are the accumulations of unconsolidated alluvial, aeolian, glacial, and residual rock materials) originate to become water containers and by which the occurrence of ground-water in them is controlled. Geologic structure is also largely controlling in the occumulation and circulation of ground-water within rock formations. The science of hydrology contributes the all-important knowledge of the origin and source of ground-water and related hydrography; hydraulics contributes the principles of ground-water movement under certain conditions, and the discharge and yield of water from underground sources. From the science of hydrostatics are obtained the principles which are largely controlling in the broader movements and circulation of the ground-water body. Many other phases of ground-water hydrology are based upon principles set forth in soil mechanics, irrigation, drainage, sewage filtration, and other special branches of engineering and geological endeavor.

Such knowledge appears to be widely scattered and impossible to obtain without extensive study of many publications. This is true, as at present there is no comprehensive text published covering the field, but study can be guided so as to direct the student of engineering or geology, who plans to practice in the West, in his search for such knowledge, if the subject be deemed of sufficient importance to justify the time spent in covering it. Some of the considerations involved in this phase of the question will be reserved for discussion in a second installment of this article.

READER INTEREST

—How Can the Publisher *Guarantee it?* —and How May the *Advertiser* Know that he is *Getting it?*

SPACE buyers may not agree upon all of the accepted standards by which advertising mediums are selected. They may, for example, hold radically opposite views as to the value of "mass coverage" versus the concentrated appeal.

But on one cardinal point the opinion of the whole advertising fraternity is unanimous. The publication must have strong reader interest. Without *reader interest* a publication is worthless as an advertising medium. Conversely, the greater the reader interest the greater the value of the medium to its advertisers.

Business men nowadays have time to read but few publications. The magazine that claims their undivided attention must dominate in reader interest. And how may it so dominate? By *concentrated appeal.* By class interest. By editorial value to ONE GROUP ONLY and by serving *that* group well.

The strength of MODERN IRRIGATION as an advertising medium lies in the fact that it affords advertisers a "rifle shot" straight to a selected group of buyers—the tremendous buying power of the irrigation and hydraulic industry. It is not for the advertiser who prefers the blunderbuss type of medium—patronized so often by concerns selling to several industries, which imagine that by using the medium of diversified appeal they may kill several birds with but a single stone. Good argument, here, for the advertiser—but how about him who counts the most, the man who reads it? Does he feel that it applies directly to *his* industry and will help him solve the daily problems of *his* particular business?

For every industry has its own highly specialized problems. *Only to a publication devoted to hydraulics exclusively* may the irrigation executive and engineer, the land owner, the contractor and the waterworks man, turn for complete, up-to-the-moment, authoritative information. Only upon the medium of concentrated, group appeal can they depend, month after month, for the current news developments of their industry, as well as for invaluable technical material.

For such mediums as this there can be no adequate substitute. They are the publisher's very best guarantee of reader interest—the highest reader interest it is possible for a publication to have. And they are the advertiser's safest assurance of a profitable return upon his advertising investment.

MODERN Irrigation

IRRIGATION FINANCE

IRRIGATION NEEDS CAPITAL -- CAPITAL NEEDS IRRIGATION

By JOHN DWIGHT NEALE

Delivered before the Irrigation Districts Association of California

MODERN RECLAMATION is no longer an individual or partnership undertaking. Large capital expenditures are involved which necessitate the issuing of bonds to be sold to private and corporate investors.

Thus the interests of a large number of people are involved in an irrigation enterprise:—The landowners and farmers; the contractor and engineers; the lawyer and the investment banker and the investor.

The silver cord of life to all communities of the arid West is the irrigation canal.

I recently visited a section of Arizona, on the lower Gila River, where no present-day signs indicate any former habitation or development, except some long unused ditches.

In 1878, irrigation of that section began, and soon families and homes and productive farms were found in the valley, and instead of the desert, fruitful harvests abounded.

This happy condition obtained for 13 years until 1891, when a great flood on the Gila washed out the temporary, farmer-built dam, changed the course of the River so that the main stream could no longer be easily dammed and diverted by the farmers and their crude tools and dirt-moving machinery, and when the silver cord was broken, it was not long until the desert crept back and instead of happy homes, fruitful farms and many indications of a settled community which obtained there 45 years ago, we now find thorns, centipedes and horned toads.

Three Lessons from Arizona

This example of an irrigation system which functioned for a time—and then ceased—demonstrates clearly at least three facts, pertinent to Western America, viz:—

Construction and maintanance of irrigation systems are no longer individual or partnership undertakings, but rather are of a type involving the public and large capital expenditure; without irrigation, much of the West is largely a desert; county, city and school district bonds, issued by western communities, can be considered no more reliable or permanent than the irrigation systems which serve the populations of those political subdivisions.

It might be an interesting and very worth-while topic for discussion by the Irrigation Districts Association of California, to seek some of the underlying causes of a condition which directly affects every western interest and community.

An Anomalous Price Situation

When City of Merced Bonds are being retailed on a 4.40 per cent basis, and Merced Irrigation District Bonds are obtainable in the same market at prices to yield nearly 6 per cent, something must be out of joint in capital's attitude, as the Merced Irrigation District includes the City of Merced and in addition thereto an area of about 180,000 acres of irrigable land, over half of which is under a high state of development.

Both City of Merced and Merced Irrigation District Bonds are payable from unlimited ad valorem taxes, and in each instance, failure to pay property taxes forfeits ownership and possession.

If unfavorable comment and publicity has led the investing public to believe that City Bonds are a safe investment, while Irrigation District Bonds are speculative, it seems high time that this Association and all thinking Californians should take such definite steps as will remove public prejudice against the securities of the West's basic industry.

Those making these comments may only be echoing reports they receive from what they deem official sources.

It should be the business of this Association to publish facts covering actual achievements of irrigated agriculture in the West and if, as has been reported, the U. S. Bureau of Reclamation does not give out the statements which are representative of actual achievements, it is certainly in order that this Association go on record here and now, by proper resolution, calling the attention of the Secretary of the Interior and the Commissioner of Reclamation to the tremendous importance of giving the newspapers, which mould public opinion so largely, representative accounts of advancement and achievement of the Reclamation Bureau, rather than statements which may tend to destroy public confidence—not only in the work of the U. S. Reclamation Service, but in the securities issued by western irrigation districts, without which no large development of a western agriculture or other western natural resource, is probable or practicable.

If the West continues to grow and achieve, irrigation must be given the earnest attention, warm sympathy and loyal support of every western business and enterprise.

Growth Depends on Irrigation

A section of our country which cannot keep even its lawns green in the summertime, without irrigation, cannot long afford to ignore a situation where credit is not encouraged to enter wholeheartedly into the development of those very things which perpetuate the growth, happiness and existence of its population.

We originally stated in this address that irrigation development is no longer an individual or partnership undertaking in which, by the contribution of a few days of work by each farmer affected, an irrigation system can be built.

We have reached the time in California when irrigation systems require large capital expenditures to build and the public is now being called upon to buy irrigation securities.

Credit follows public confidence. Let all Californians make sure that real confidence exists and endures.

Manufacturers' and Dealers' Place In Pump Sales Discussed by W. I. E. A.

HOW THE USER of irrigation equipment may be best served, for his own ultimate good and the success of the manufacturer and dealer as well, was the question that received the greatest share of attention from the members of the Western Irrigation Equipment Association, in session at Fresno, California, on April 16.

In the general discussion that featured the business meeting, the prevailing opinion was that the local dealer should carry on the sale of pumping plants and similar equipment, because of his ability to render instant and understanding service to the user.

Several manufacturers expressed a cordial and hearty agreement with this policy in the abstract, but objected that its defect was in a lack of dealers who appreciated their responsibility and opportunity. "There are not enough of the right sort of dealers to go 'round," was the manufacturers' complaint.

Discussion on this problem, which is a real one involving the interests of maker, dealer and user equally, brought out the dealers' position that they must be given the chance to sell and service the equipment if they are to maintain their position in the business, while the manufacturers respond that if the dealers assume this responsibility they must live up to it in efficient and reliable service. The good offices of the Western Irrigation Equipment Association, as the organization uniting both interests, and serving for the presentation and discussion of their mutual problems, were commended as the best solvent for their troubles.

Business and Fun

The Fresno meeting, as usual, was a lively one in both business and banquet sessions. Business transacted included:

The adoption of a constitutional amendment providing that the president of the association may not succeed himself, and an amendment of the by-laws providing for the appointment of a nominating committee in advance of the election of officers.

The submission of six additional sheets for the association's data book by C. F. Zimansky, president, and the appointment of a committee comprised by E. M. Breed, C. F. Zimansky, E. K. Barnum and H. W. Brown to examine and pass upon the accuracy of all material submitted for inclusion in this hand-book.

A report on the activities of the publicity committee, by C. B. Noyes, chairman, who submitted several designs for an official association medallion and predicted that the right kind of publicity would help to iron out the difficulties between the buyer and seller of equipment.

Ben D. Moses, representing the California Committee on the Relations of Electricity to Agriculture, reported progress, but not completion, on the standard form of contract which is being worked out by the Association to cover the terms and guarantee of pump sales by its members. He also reported that the Pacific Hydraulic Engineering Association is lending effective cooperation to this effort.

A greeting and proffer of close cooperation was tendered on behalf of the Hydraulic organization by E. M. Breed, its vice-president.

Next Meeting July 30

C. B. Noyes, paying tribute to the interest and activity of well-drillers in the irrigation industry, advocated that the problems of this element of the association's membership should be given more emphasis, and it was decided that the next meeting of the organization, which will be held at Stockton, July 30, will be largely devoted to well-drillers' concerns. J. E. Lundy, General Manager of the Sterling Pump Works, Inc., will be general chairman of the arrangements committee for the July 30 meeting at Stockton.

A. K. Flynn, well driller of Orange Cove, was accepted as a member, cordially pledging his best efforts to advance the association's interests.

Seventy-five were present at the evening banquet at the Hotel Fresno, with A. M. (Jack) Frost in the spot-light as toastmaster. W. I. E. A. talent provided the music, and the volunteer actors, vocalists and yodelers discovered among its membership stood all over the floor and the piano while they made the welkin ring.

Two interesting talks were presented, both of which had direct application to irrigation problems. H. N. Carroll, of the San Joaquin Light and Power Corporation, Fresno, brought out some interesting information when he discussed "Cotton in the San Joaquin Valley."

Seventy thousand acres in the San Joaquin Valley are under pump irrigation, and the average head for cotton is 77 feet. More than $400,000, it is estimated, has been spent for irrigation equipment for use in irrigating cotton in the valley during the past two years.

Max W. Enderlein, Fresno consulting engineer, spoke on "Underground Water Supply of the San Joaquin Valley," urging the necessity of conserving irrigation water by preventing seepage and evaporation. Mr. Enderlein stressed the importance of using underground pipe wherever possible.

SURVEY *of* HYDRAULIC DEVELOPMENT

As Shown by Official Records of the Month -- Local, State, and Governmental

Permits Issued

Among the more important permits to appropriate water issued by the Department of Public Works, Division of Water Rights of California, during the month of April, 1926, were the following:

Permit No. 2452, Application No. 3544 (Siskiyou County). Issued to Montague Irrigation District of Montague, California, April 3, 1926, for 55,000 acre feet per annum from Shasta River in Sec. 25, T 43 N. R 5 W. for use for irrigation of 19,500 acres in the Montague Irrigation District. Estimated cost $1,200,000.

Permit No. 2453, Application No. 3555 (Siskiyou County). Issued to Montague Irrigation District of Montague, California, April 3, 1926, for 15,000 acre feet per annum from Parks Creek in Sec. 29, T 42 N, R 5 W. for use for irrigation of 19,500 acres within the Montague Irrigation District.

Permit No. 2454, Application No. 4482, (San Mateo County). Issued to Pigeon Point Lumber Co. of Pescadero, California, April 9, 1926, for 10 cubic feet per second from Gazos Creek in Sec. 33, T 8 S, R 4 W. for use for power purposes in Sec. 33, 68 T. H. P. to be developed. Estimated cost $4,000.

Permit No. 2455, Application No. 4057 (Eldorado County). Issued to Eldorado Power Co. of San Francisco, California, April 12, 1926, for 250 cubic feet per second and 7500 acre feet per annum from Silver Park in Sec. 35, T 11 N. R 15 E. for use for power purposes in Sec. 28, 24858 T. H. P. to be developed. Estimated cost $3,659,000.

Permit No. 2456, Application No. 4687 (Eldorado County). Issued to Eldorado Power Co. of San Francisco, California, April 12, 1926, for 7500 acre feet per annum from Silver Fork in Sec. 35 T 11 N, R 15 E. for use for power purposes in Sec. 15, T 11 N. R 12 E. 122,564 T. H. P. to be developed.

Permit No. 2457, Application No. 4686 (Eldorado County). Issued to Western States Gas & Electric Co. of Stockton, California, April 12, 1926, for 7500 acre feet per annum from Silver Fork in Sec. 35, T 11 N, R 15 E. for use for power purposes in Sec. 20, T 11 N, R 11 E. 27982 T. H. P. to be developed.

Permit No. 2458, Application No. 4868 (Eldorado County). Issued to Henry Bacchi of Lotus, California, April 13, 1926, for 0.05 cubic feet per second from Indian Creek in Sec. 6, T 11 N, R 10 E. for domestic use, stock watering and irrigation of 4 acres in Sec. 12, T 11 N. R 9 E. Estimated cost $15,00.

Permit No. 2459, Application No. 4228 (Amador & Calaveras Counties). Issued to East Bay Municipal Utility District of Oakland, California, April 17, 1926, for 310 cubic feet per second and 217,000 acre feet per annum from Mokelumne River in Sec. 26, T 5 N, R 10 E. for use for municipal Utility District. Estimated cost $80,000.

Permit No. 2460, Application No. 4796 (San Bernardino County). Issued to Claude W. Chapman of Venice, California, April 26, 1926, for 0.001 cubic foot per second from an unnamed spring, in Sec. 22, T 2 N. R 1 W. for use for domestic purposes in Sec. 22. Estimated cost $225.00.

Permit No. 2461, Application No. 4624 (Siskiyou County). Issued to G. C. Williams of Happy Camp, California, April 26, 1926, for 20 cubic feet per second from Oak Flat Creek, in Sec. 19, T 16 N, R 7 E. for use for placer mining near point of diversion. Estimated cost $8,000.

Permit No. 2462, Application No. 4564 (Eldorado County). Issued to Mrs. W. W. Price & E. G. Galt of Fallen Leaf and Tallac, California, April 27, 1926, for 1 cubic foot per second and 464 acre feet per annum from Grass, Gilmore, Susie, Halfmoon & Heather Lakes in Secs. 7, 8, 14, 17, 19, 21, T 12 N. R 17 E. for use for power purposes in Sec. 14, 119 T. H. P. to be developed.

Permit No. 2463, Application No. 4806 (Monterey County). Issued to Alfhild Borgstrom of San Francisco, California, April 27, 1926, for 0.05 cubic foot per second from The Sunshine Springs in Sec. 20, T 20 S. R 3 E. for use for irrigation of 2½ acres near point of diversion. Estimated cost $1250.00.

Permit No. 2464, Application No. 4822 (Butte County). Issued to P. N. Ashley of Biggs, California, April 28, 1926, for 7 cubic feet per second from Lateral A of Reclamation District 833, in Sec. 3, T 18 N. R 2 E. for use for irrigation of 305 acres near point of diversion. Estimated cost $1400.

Permit No. 2465, Application No. 4859 (Butte County). Issued to Bill Gianella of Marysville, California, April 28, 1926, for 3 cubic feet per second from North Honcut Creek in Sec. 2, T 18 N. R 4 E. for use for irrigation of 265 acres near point of diversion. Estimated cost $1500.

Permit No. 2466, Application No. 4873 (Los Angeles County). Issued to Frank P. Sentous of Newhall, California, April 29, 1926, for 0.18 cubic foot per second from German Canyon in Sec. 2 T 3 N. R 15 W. for use for domestic and irrigation of 15 acres in Sec. 2. Estimated cost $100.

Permit No. 2467, Application No. 4915 (Eldorado County). Issued to James Keane et al. of Sacramento, California, April 29, 1926, for 0.62 cubic foot per second and 20 acre feet per annum from Hubbard & Indian Creeks in Sec. 7, T 11 N, R 10 E. for use for domestic and irrigation of 50 acres in Sec. 7. Estimated cost $500.

Grants Public Utility Certificate

The California Railroad Commission has granted a certificate to W. F. Kime to operate a public utility water system in Tract No. 5775, Los Angeles county and has fixed a schedule of rates therefor.

Applications Filed

Among the applications for permit to appropriate water filed with the State Department of Public Works, Division of Water Rights, (California) during the month of April were the following:

Application No. 4985 (Ventura County). Gregory M. Creutz, 601 Pershing Square Bldg., Los Angeles, California, for 3 cubic feet per second and 200 acre feet per annum from Little Sycamore Canyon, tributory to Pacific Ocean. To be diverted in Sec. 22, T 1 S, R 20 W. S. B. M. for irrigation and domestic purposes on 320 acres.

Application No. 4986 (Ventura County). Guy T. Stetson and Henry S. Nixon, Trustees for the proposed Ojai Irrigation Dist. Care J. B. Lippincott, 543 Petroleum Securities Bldg., Los Angeles, California, for 100 cubic feet per second from N. Fork Matilija Creek, tributary to Ventura River. To be diverted in Sec. 20, T 5 N. R 23 W. S. B. M. for irrigation and domestic purposes on 1500 acres. Estimated cost $30,000.

Application No. 4987 (Ventura County). Gregory M. Creutz, 601 Pershing Square Bldg., Los Angeles, California, for 3 cubic feet per second and 200 acre feet per annum from Little Sycamore Canyon, tributary to Pacific Ocean. To be diverted in Sec. 22, T 1 S, R 20 W. S. B. M. for irrigation and domestic purposes on 480 acres.

Application No. 4988 (Ventura County). Gregory M. Creutz, 601 Pershing Square Bldg., Los Angeles, California, for 2½ cubic feet per second and 200 acre feet per annum from branch, Little Sycamore Canyon, tributary to Pacific Ocean. To be diverted in Sec. 14, T 1 S. R 20 W. S. B. M. for irrigation and domestic purposes on 640 acres.

Application No. 4989 (Butte County). Margaret A. Straughan, care Jerome D. Peters, Bank of Italy Bldg., Chico, California, for 2.8 cubic feet per second from West Branch Butte Creek, tributary to Sacramento River, to be diverted in Sec. 15, T 24 N. R 3 E. M. D. M. for power purposes in Sec. 22, T 24 N. R 3 E. M. D. M.

Application No. 4990 (Inyo County). William Hyder, 5671 Lemon Grove Ave., Los Angeles, California, for 0.25 cubic foot per second from Arrasta Spring tributary to Panamint Valley. To be diverted in Sec. 16, T 22 S. R 46 E. M. D. M. for mining and domestic purposes.

Application No. 4991 (San Joaquin County). Pescardero Recl. Dist. No. 2058, care Amos Jones, Box L-1, Trady, California, for 100 cubic feet per second from Tom Paine Slough and Paradise Cut, tributary to Lower San Joaquin River. To be diverted in Sec. 4, T 2 S. R 5 E. M. D. M. and 8 other points on Paine Slough and Paradise Cut, for irrigation purposes on 8,350 acres.

Application No. 4992 (Butte County).

Edith ad Victor Hoag, Gridley, California, for 1.85 cubic feet per second from Lateral E—1 A Recl. Dist. 833 tributary to Sacramento River. To be diverted in Sec. 3, T 17 N. R 2 E. M. D. M. for irrigation purposes on 74 acres of rice. Estimated cost $500.

Application No. 4993 (Butte County). G. R. Estes and Victor Hoag, care Grover R. Estes, Gridley, California, for 2.5 cubic feet per second from Main Canal—Recl. Dist. 833, tributary to Sacramento River via Butte Creek. To be diverted in Sec. 28, T 18 N. R 2 E. M. D. M. for irrigation purposes on 100 acres of rice in Sec. 28, T 18 N. R 2 E. M. D. M. Estimated cost $1,000.

Application No. 4994 (Ventura County). Gregory M. Creutz, 601 Pershing Square Bldg., Los Angeles, California, for 2 cubic feet per second and 200 acre feet per annum from Little Sycamore Canyon, tributary to Pacific Ocean. To be diverted in Secs. 3 and 10, T 1 S, R 20 W. S. B. M. for irrigation and domestic purposes on 160 acres in Sec. 10, T 1S. R 20 W. S. B. M.

Application No. 4995 (Ventura County). James Erwin, care Navy Oil Co., Box L, Taft, California, for 0.1 cubic foot per second, from unnamed stream tributary to Hopper Creek and Santa Clara River. To be diverted in Sec. 10, T 4 N. R 10 W. S. B. M. for domestic and irrigation purposes on 6 acres in Sec. 10, T 4 N. R 19 W. S. B. M.

Application No. 4996 (Humboldt County). A. W. Way, care Wynn Meredith, Box 527, Eureka, California, for 0.25 cubic foot per second from unnamed stream tributary to Mattole River. To be diverted in Sec. 30, T 2 S. R 1 W. H. M. for irrigation and domestic purposes on 30 acres in Sec. 30, T 2 S. R 1 W. H. M. Estimated cost $300.

Application No. 4997 ((1) Riverside (2) Imperial County). City of San Diego, office of City Attorney, City Hall, San Diego, California. To be diverted for 135 cubic feet per second from Colorado River tributary to Gulf of California. To be diverted in (1) Sec. 14, T 3 S. R 23 E. S. B. M. (2) Sec. 25, T 15 S. R 23 E. S. B. M. for municipal purposes in City of San Diego.

Application No. 4998 (Santa Barbara County). U. S. Dept. of Agriculture, Forest Service, Santa Barbara National Forest, Federal Bldg., Santa Barbara, California, for .025 cubic foot per second, from Paradise Creek, tributary to Santa Ynez River. To be diverted in Sec. 4, T 5 N. R 28 W. S. B. M. for domestic purposes in Sec. 4, T 5 N. R 28 W. S. B. M. Estimated cost $300.

Application No. 4999 (Tuolumne County). Sierra and San Francisco Power Co., 625 Market Street, San Francisco, California, for 9,000 acre feet per annum from Herring Creek, tributary to South Fork Stanislaus River. To be diverted in NE¼ Sec. 15, T 4 N. R 18 E. M. D. M. and SW¼ Sec. 15, T 4 N. R 18 E. M. D. M. for power purposes in Spring Gap, Stanislaus and Melones Power Houses. Estimated cost $100,000.

Application No. 5000 (Nevada County). Jonas Hirsch, Overland Hotel, Reno, Nevada, for 1 cubic foot per second from Juniper Creek tributary to Truckee River. To be diverted in Sec. 34, T 18 N. R 17 E. M. D. M. for power purposes in Sec. 34, T 18 N. R 17 E. M. D. M. 25 T. H. P.

Application No. 5001 (Alameda County). County of Alameda, office of Dist. Attorney, of Alameda County, Oakland, California, for 0.37 cubic foot per second and 60 acre feet per annum from Arroyo Del Valle, tributary to Alameda Creek. To be diverted in Sec. 4, T 4 S. R 2 E. M. D. M. for irrigation and domestic purposes on 30 acres. Estimated cost $30,000.

Application No. 5002 (Amador & Calaveras Counties). East Bay Municipal Utility Dist., 1924 Broadway, Oakland, California, for 750 cubic feet per second and 25,000 acre feet per annum from Mokelumne River, tributary to San Joaquin River. To be diverted in Sec. 16, T 5 N. R 11 E. M. D. M. for power purposes in Sec. 16, T 5 N. R 11 E. M. D. M. Estimated cost $800,000.

Application No. 5003 (Siskiyou County). Morgan A. Gunst, 601 3rd Street, San Francisco, California, for .0012 cubic foot per second from unnamed spring tributary to Klamath River. To be diverted in Sec. 24, T 47 N. R 6 W. M. D. M. for domestic and irrigation purposes on 10 acres in Sec. 25, T 47 N. R 6 W. M. D. M. Estimated cost $1,000.

Application No. 5004 (Yuba County). Pacific Gas & Electric Co., 245 Market Street, San Francisco, California, for 15,000 acre feet per annum from North Fork of Yuba River, tributary to Feather River. To be diverted in Sec. 24, T 18 N. R 7 E. M. D. M. Re-diversion in Sec. 25, T 18 N. R 7 E. M. D. M. for power purposes in Sec. 16.

Will Issue Securities

The Roseville Water Company has been authorized by the California Railroad Commission to issue on or before December 15, 1926, $61,000 of six and one-half per cent bonds, for the purpose of refunding its outstanding six per cent bonds, or sell on or before December 15, 1926, said $61,000 of six and one-half per cent bonds, at not less than 91 per cent of face value, plus accrued interest, and to use the proceeds, other than accrued interest, to redeem said $61,000 of six per cent bonds. The Commission also authorized the same company to issue and sell on or before December 15, 1926, $119,000 of six and one-half per cent bonds, and to use the proceeds thereof to pay outstanding indebtedness and to finance additions, betterments and improvements.

Bond Issue Authorized

The Hermosa-Redondo (California) Water Company has been authorized by the State Railroad Commission to issue and sell on or before December 1, 1926, $50,000 of its Series "A" mortgage, six and one-half per cent bonds, due December 1, 1953, at not less than 95 per cent of face value, plus accrued interest, $37,000 of its preferred stock at not less than 91 per cent of par value, and $26,500 of common stock at not less than 85 per cent of par value, and to use the proceeds to reimburse its treasury for capital expenditures and for additions and betterments.

To Qualify Directors

Ocean Park Heights Water Company has applied to the California Railroad Commission for authority to issue five shares of common stock to its officers and directors, for the purpose of qualifying such officers. The Gardena Valley Water Company has applied for permission to issue five shares of stock for the same purpose.

Would Revise Rates

Moor Park Farmers Water Company, furnishing water for irrigation and domestic purposes in Moor Park District, has applied to the California Railroad Commission for permission to revise its rates, rules and regulations for delivery of irrigation water.

OREGON

Among the more important applications for permit to appropriate water filed in the office of Rhea Luper, state engineer of Oregon, during April were the following:

W. G. Allen of Salem, covering the appropriation of water from Jones and Finney Lakes and Stream for irrigation of 240 acres in Marion County.

August Mooreman of Shaw, covering the appropriation of water from an unnamed stream for irrigation of 30 acres in Marion County.

J. O. Jones of Hood River, covering the appropriation of water from an unnamed stream for irrigation of 15 acres and development of 8 theoretical horsepower in Hood River County.

J. B. Stobie of Camas Valley, covering the appropriation of water from unnamed creeks for irrigation of 295 acres in Douglas County at a cost of $1500.

M. W. Mahoney of Portland, covering the appropriation of water from Mission Creek for irrigation of 103.25 acres in Marion County.

Harry V. Gates of Terrebonne, covering the appropriation of water from Crooked River for operating pumps and for the irrigation of 200 acres in Jefferson County.

J. R. Hills of Dexter, covering the appropriation of water from Hills Creek for fluming lumber and for irrigation of 600 acres in Lane County.

Joe Mash of Huntington, covering the appropriation of water from Becker Creek for irrigation of 25 acres in Malheur County.

Robert Meyer of Grants Pass, covering the appropriation of water from Onion Creek for supplemental irrigation of 18 acres in Josephine County.

Harry A. Johnson of Dufur, covering the appropriation of water from Eight Mile Creek and Tamarack Creek for irrigation of 20 acres in Wasco County.

Oswald West of Portland, covering the appropriation of 50 second feet of water from an unnamed stream leaving the Deschutes River on its East Bank approximately 1600 feet south of Lava Island in Section 27, Tp. 18 S., R 11 E., W. M., for irrigation of 2,000 acres of land in Deschutes County.

Mr. Grant Winters of Camas Valley, Oregon, covering the appropriation of water from an unnamed creek, tributary of Coquille River, for irrigation of 8 acres, in Douglas County, at a cost of $400.

Mr. F. C. Vaughn of Baker, Oregon, covering the appropriation of water from overflow of reservoir, City of Baker water supply, for irrigation of 95 acres in Baker County.

The Portland Electric Power Company of Portland, Oregon, covering the appropriation of water from Clackamas River, tributary of Willamette River, for generation of hydroelectric power in Clackamas County at a cost of $1,560,000.

Mr. Walt Smiley of Wilsonville, Oregon, covering the appropriation of water from an unnamed creek tributary of Willamette River for irrigation and power purposes in Clackamas County.

Gustav E. Stein of Sherwood, Oregon, covering the appropriation of water from Stein Creek, tributary of Willamette River, for irrigation of 40 acres and power purposes in Clackamas County, at a cost of $1,000.

Mr. J. B. Stobie of Camas Valley, Oregon, for the construction of Stobie Reservoirs for the storage of 100 acre feet from unnamed streams, tributaries of Coquille River. The stored water is to be used for irrigation.

Public Utility or Mutual Company?

Miller & Lux, Inc., has filed a petition for a rehearing of the California Railroad Commission of the recent order of the Commission in which the water system maintained by that corporation in the Miller and Lux Colony in the vicinity of Firebaugh and Mendota, Fresno County, was held by the Commission to be a public utility, and the owners thereof directed to refund to consumers moneys collected through the increasing of rates without authority of the Railroad Commission. Petitioners allege that the Railroad Commission erred in finding the said water system to be a public utility, instead of a mutual water system, as contended by the owner.

L. A. Company Would Expand

The Los Angeles Water Service Company has applied to the California Railroad Commission for permission to acquire and operate the properties of Consolidated Water and Development Company, South Park Water Company, Lawndale Land and Water Company, Melvin Place Water Company, and The Calhoun Plant, and also for permission to issue and sell 4,000 shares of common capital stock in part consideration of the transfer of said properties, and also to issue and sell $385,000 of bonds, bearing interest at rates of seven per cent per annum, for the purpose of financing extensions and improvements.

Water Held Not Harmful

Liberty Acres Water Company, operating near the town of Hawthorne, has been authorized by the California Railroad Commission to place in effect a new schedule of rates, including both flat rates and meter rates, and has been directed to take proper steps to assure a pure clean and unoffensive supply of water. The Commission found that the present complaint against the supply is due to sulphur contents and insufficient flushing of the mains but that the water is potable and not unhealthful.

To Issue $700,000 Bonds

The Monterey County, (California) Water Works has been authorized by the State Railroad Commission to issue $700,000 of first mortgage six per cent 30-year bonds for the purpose of financing acquirement of the water properties from Del Monte Properties Company and to finance additions and betterments, and to reimburse applicant's treasury for surplus earnings expended for additions and betterments.

Asks Higher Rates or Quit

The Stockton and Mokelumne Canal Company has applied to the California Railroad Commission for permission to discontinue service, or for an increase of rates, alleging that it cannot operate successfully under the present rates. Petitioner asks that if increased rates are granted they be fixed on a basis of returning eight per cent per annum on a valuation of $209,115.18.

Limoneira System Taken Over

The California Railroad Commission has granted a certificate to Farmers Irrigation Company, a corporation, to operate the water system in the territory formerly served by Limoneira Company near Santa Paula, and to charge the same rates now in effect on that system.

Out of Service

Laurel Canyon Land Company has applied to the California Railroad Commission for permission to discontinue service of water and to remove its equipment, its territory now being served by the Los Angeles City Water Works.

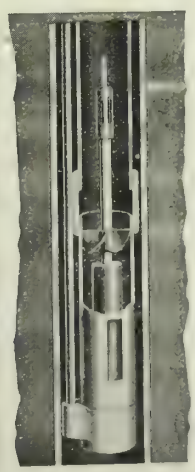
IT'S THE *BOTTOM OF THE WELL* THAT COUNTS!



A great NEW principle for pumping water has been evolved. The advantages of the air-lift have long been recognized. The idea of an air-driven turbine *pump*, however, combining every advantage of the ordinary air-lift—with its marked economies of cost and upkeep—is now a practical reality. No more sand troubles—no more expensive repairs and shutdowns. All parts requiring attention or repair are *on the surface*. Cut at left tells the story. Agents wanted in open territory. Send for literature.

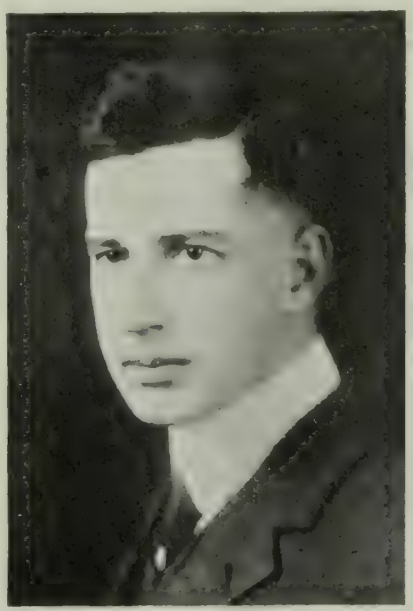
AMONG OUR CONTRIBUTORS

Editorial Jottings About Current and Forthcoming Feature Articles, Dealing With Practical Problems of Hydraulics, and the Men Who Have Written Them

COVERAGE of the diversified fields of irrigation and water development is the goal of MODERN IRRIGATION. In this issue, a suggestion of the wide scope of the magazine is indicated by the numerous departments touched, including management, engineering, cultivation, conservation, water works, law, finance, reclamation, etc. And of course these are not all. But the purpose of the magazine is to contact with every field which is directly allied to the hydraulic industries, and to make itself the publication of the water developers and water users of the entire west.

GEORGE L. SWENDSEN, who writes on "Fundamentals of District Management," is both an engineer and a manager, and in himself is an able illustration of the fact that these capacities may be successfully combined. He is a Harvard graduate who has spent twenty-five years in irrigation work in California, Idaho and Utah. From 1903 to 1906 he was district engineer in the U. S. Reclamation Service. From 1906 to 1917 he was connected with the construction and development of irrigation projects in Idaho, and in 1917 he came to California, where for three years he served in the direction of construction and operation of the deep-well pumping system of the Boston Land Company's project in the San Joaquin Valley. Since 1920 he has been in his present position as chief engineer and general manager of the Fresno Irrigation District, which includes 243,000 acres, with 10,200 water users. His article is prepared at the request of this magazine, based on a paper delivered to a recent meeting of the Irrigation Districts Association of California.

HYDE FORBES, who discusses the importance of ground-water studies to both student technologists and practicing engineers and geologists, is himself both an engineer and a geologist, and has specialized, in training and practice, in ground-water investigations and development for water supply and irrigation, and in the treatment of excess ground-water in drainage problems. His career, since his graduation from Stanford University in 1913, has included varied work of this sort for western irrigation organizations and municipalities. His present work is mainly of a consulting character, with offices in San Francisco. Studies of ground-water conditions under his direction have very thoroughly covered California from one end to the other. The latest task of the kind on which he has been engaged is a study of the effect of pumping ground water from the Owens Valley artesian areas by the city of Los Angeles.



PROF. F. J. VIEHMEYER

F. J. VIEHMEYER is a member of the faculty of the University of California, Department of Irrigation Investigations and Practice, who with his colleagues, is doing an invaluable work for irrigation by approaching its practices and doctrines in the spirit of scientific inquiry, and establishing by experimental evidence the foundations upon which the science of irrigation rests.

MALCOLM MUIR is vice-president of the McGraw-Hill Publishing Company, New York City, well known technical publishers. His interest in that fundamental problem of irrigation, reforestation, is evidenced by his leadership of the Reforestation Committee of the Associated Advertising Clubs of the World.

PAUL BAILEY's contribution, describing the ingenious plan which has been conceived to restore the equilibrium between water and land in the great interior valley of California, will be read with interest not only in that state, but by engineers everywhere, for it represents a truly unique project in the history of irrigation engineering. Mr. Bailey is deputy state engineer of California.

D. W. SULLIVAN is an irrigation executive of broad experience and keen interest in the problems of management and engineering. His short article describing the work which his company has done in repairing irrigation ditches is a practical suggestion for many who may be faced by similar problems.

W. M. MERTZ is a well-known citrus grower of Southern California, with interests in several parts of the state. His home is in Ontario. The article on the merits of the application system for citrus irrigation is the first part of a paper which he recently presented to the Citrus Institute, the second installment of which will be ready for an early issue.

CARL WILSON, Sc. D., is a graduate of Yale University, who has spent his professional career in the study of the problems of domestic water supply from the standpoint of the bacteriologist and chemist. Twenty years of this time he has been a resident of Los Angeles, and for twelve years has been connected with the city water department. His practice has made him conversant with water supply conditions obtaining in practically every part of the western United States and Mexico, and as the head of the largest and best-equipped laboratory in the west, he is contributing largely to the advancement of that important branch of water-works knowledge.

HANKINS & HANKINS, San Francisco attorneys, who regularly conduct for MODERN IRRIGATION the department devoted to legal and judicial matters, are attorneys for the Glenn-Colusa Irrigation district, and are specialists in this phase of law.

JOHN DWIGHT NEALE is identified with the J. R. Mason Company, leading irrigation security dealers, and is a crusader in the interests of irrigation and reclamation credit.

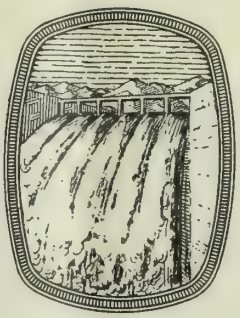
PETROLEUM WORLD 626 S. SPRING ST., LOS ANGELES, CALIF. MODERN IRRIGATION

OWEN D. YOUNG

Chairman of the Board of Directors of the General Electric Company; an international figure by virtue of the service which he rendered in connection with the post-war economic rehabilitation of Europe, and a dominant personality in the large and powerful group of corporations known generically as "the power companies." Addressing a convention of public utility executives, in May, Mr. Young made a statement touching the attitude of the power interests toward future development of the country's water resources that has been regarded a most significant pronouncement.

MODERN Irrigation
The Magazine of Applied Hydraulics



Volume II JUNE, 1926 Number 6

The Progress *of* Irrigation

AGRICULTURE is apparently on the up-swing of prosperity. Although there is much talk of "helping the farmer"—talk which probably will materialize in nothing more than good advice, or, worse, some uneconomic expedient for exchanging public moneys for farmers' votes—the farmer seems to be well on the way out of his slump and quite well able to help himself. Especially is this true as regards the far west.

A recent observer, writing of the farm market in the western states, cites a gain of $16,000,000 in the value of California farm products produced in 1925 over those produced in 1924, and says:

"Best of all, the recent agricultural improvement seems to have included not only all of California, but also the entire northwest and southwest. Even Idaho and Montana, almost ruined during post-war depression, have staged one of the most remarkable business recoveries in history. A recent survey of Idaho, Oregon and Washington disclosed a gain in farm purchasing power of more than 25 per cent."

Another observer points out an obvious trend toward breaking up large holdings of land in the far west, of which the recent subdivision of the tremendous Miller & Lux properties was typical, and comments: "The rapid increase in the *number of farms* throughout the west is probably the most significant development in relation to the present trend of agriculture."

Much of the credit for this renascence of farm prosperity in the west must be ascribed to irrigation; and that includes not only one phase of irrigation, but all phases—adequate financing, able engineering, strong organizing, competent management, and careful husbandry. At the same time it augurs well for irrigation's further advance. The rural west is entering upon a favorable aspect of the business cycle, and irrigation will flourish as a result.

OWEN D. YOUNG, chairman of the Board of Directors of the General Electric Company, who became an international figure as America's representative in councils for the economic rehabilitation of Europe, made a statement in May before the annual convention of the public utilities companies that will be read with deep interest by every one who appreciates the immense importance of what the "power companies" think about the development of the nation's water resources.

Mr. Young made an appeal for a broad national outlook on the part of both the corporations engaged in the development of power and the advocates of government water developments, and for the destruction of the animosities and misunderstandings that have clouded the relationships of these varied agencies of development and conservation. He said:

"While this debate goes on, vast rivers go unharnessed for power, waterways are undeveloped, floods drown us and droughts devour us. May I not call for a broader view in the public interest from the representatives of both the utilities and the public? Can we not find a way by which the sovereign powers of the states may be recognized in the location, construction and ownership of these tremendous structures in great rivers supplying government services as well as power?"

Mr. Young pled for a recognition, on the part of the factions too often opposed, of the part played by each other in the necessary development of the waters of the nation. This is a significant indication of a conviction that what can not be accomplished by either when they are in violent opposition, might well and wisely be accomplished if they were in harmonious agreement.

The key thought of his remarks was the hint that many of the objections to public ownership which, from time immemorial, have been urged against government development, may not be valid in the case of great rivers, international or interstate in ownership, where flood-control, navigation, irrigation and power are correlative objects. In his address as reported in the New York press, he said:

"Where vast rivers, either on international boundaries or within the United States, require development for several purposes, such as navigation, irrigation and flood control as well as for power, there arises a new kind of question which is wholly unrelated to the old controversy of government vs. private ownership."

AS HAD BEEN generally predicted by this magazine and other observers, the Boulder Canyon Project Act, fathered by Senator Johnson and Congressman Swing of California, was passed over without definite action until the second half of the Congressional session, which meets in December. The particular hurdle on which it faltered, after successfully clearing the barrier of the Senate committee, was the House Committee on Irrigation and Reclamation. On May 22 the committee adopted, by a vote of 9 to 6, a motion to postpone consideration of the measure "without prejudice" until the next session.

The motion to defer consideration was offered by Representative Carl Hayden, of Arizona, and he was supported in the vote by the Democratic members of the Committee and two Republicans. The vote on the motion for delay was:

> For—Hayden of Arizona; Hudspeth of Texas, Lankford of Georgia, Reed of Arkansas, Allgood of Alabama, Whittington of Mississippi, Morrow of New Mexico, Democrats, and Leatherwood and Allen, Republicans.
>
> Against—Smith of Idaho, Leavitt of Montana, Winter of Wyoming, Swing of California, Arentz of Nevada and Davenport of New York, Republicans.

Although the proponents of the Swing-Johnson bill have denounced the action of the house committee as an example of "playing politics" with a national, non-political issue, charging that the congressmen feared to take action because of its possible reflection in the coming congressional elections, neither its advocates nor its opponents regard the resultant delay as particularly significant. Its effect is merely to postpone action, which would probably have been postponed anyway, for one reason or another, until the latter half of the session.

THERE has been a large spring rainfall in many parts of the west, especially throughout California. As a result, paradoxical as it may seem, there is an increased forest-fire danger to be faced in these regions during the summer months.

George H. Cecil, forest supervisor in California, has broadcast a general warning of this situation, explaining the effect of the heavy rainfall in adding to the fire hazard.

"The more rain, the more fires," says Mr. Cecil. "This may seem contradictory to the casual observer, but it is nevertheless the truth. The splendid rains, so many of which came late in the season, gave new life to the forests' undergrowth and the wild grasses, causing the latter to grow to unusual lengths. Recent dry winds, passing over these grasses and weeds, have caused them to go to seed and die early.

"Experience teaches us that this growth, beautiful and welcome as it is when fresh and green, constitutes an extraordinarily bad fire hazard later in the season."

Of all classes of men, irrigators and irrigationists should be most alive to every factor which affects the forests, the source of the material which is the alpha and omega of the irrigation industry. While they are always on the alert to make their influences felt on behalf of protecting the forests, they will be especially active during the season of 1926 on account of the increased need.

Cotton is King – but *Irrigation* Is the *Power* Behind the *Throne*

Water Plays Leading Role in Creation of Great New Western Industry in the San Joaquin Valley and Constitutes Major Item in Production Cost

By H. N. CARROLL

WATER, most of it pumped, is playing the leading role in developing in the great interior valley of California a tremendous cotton growing industry. The cotton grower must take careful thought for his irrigation supplies, for, although it is irrigation that makes the successful production of cotton possible in this region, water and the labor of its application also constitute one of the largest items in the cost of growing and picking the crop.

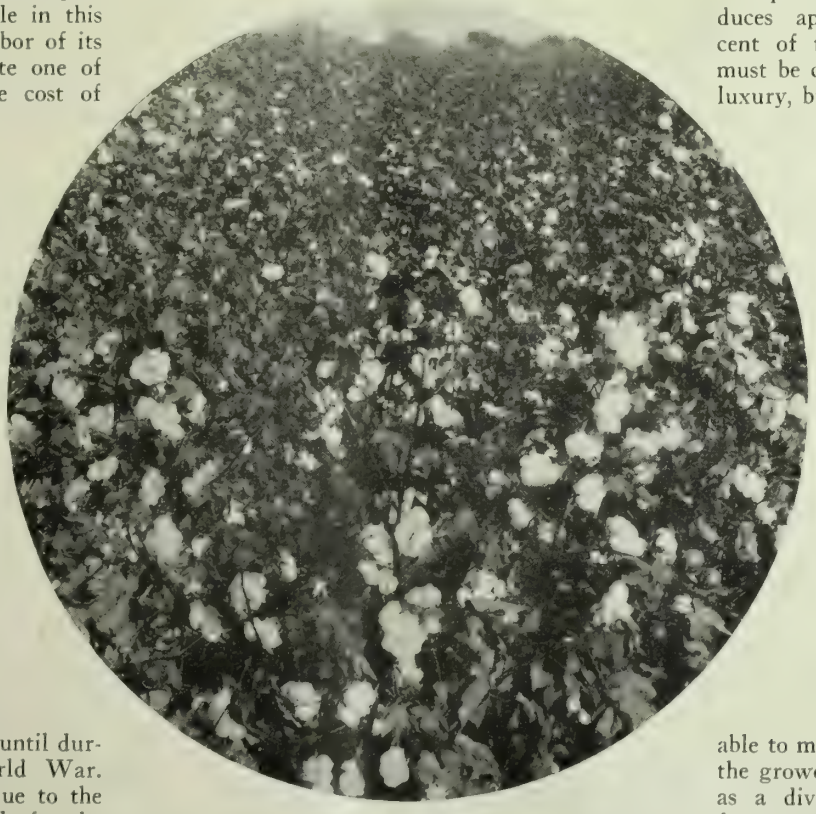
Great interest has recently been aroused in the cotton-growing possibilities of the San Joaquin Valley, and some of the publicity attending this widespread interest has tended to give the impression that cotton is an entirely new crop to this region. This is not true, however, as public records show that cotton has been grown in the San Joaquin Valley in varying quantities for the past 25 years.

It is true, however, that it was not grown in commercial quantities until during and since the World War. This was undoubtedly due to the fact that it was impossible for the cotton grower of the San Joaquin Valley to compete with cheap negro labor and natural rain-fall conditions of the big cotton growing states of the South in the days before 1914, when it was possible to contract cotton chopping to negro labor for 50 cents an acre, and when all other labor in connection with the growing of this crop was in exact proportion.

These were the days when cotton could be raised for from 5 to 10 cents a pound, and commanded from 5 to 10 cents per pounds in the open market. Those were also the days before the destructive ravages of the boll weevil, an insect that has extracted a greater toll from the pockets of the American public than any other insect pest in the history of the United States.

"Overproduction" Idle Talk

In 1923 the valley harvested a crop of 10,000 acres of cotton; in 1924 this acreage had risen to 38,000 acres and jumped to 98,000 in 1925. Such has been the increase that it has already given rise to the cry of over-production, but the people who claim that there is any danger of the present acreage of cotton in the San Joaquin Valley in any way influencing the market have not examined this subject very closely. The average world production of cotton is upwards of twenty million bales annually, and this year, with a potential 80,000 bales, the San Joaquin Valley would have only three-tenths of one per cent of the total crop of the entire world.



A San Joaquin cotton field—there were ninety-eight thousand acres like this in the valley in 1925—and more coming.

If the valley produced 200,000 bales of cotton it would still have less than one per cent of the world's production. We, in the San Joaquin Valley, when we speak of over-production, are prone to think in terms of fruit and especially raisins. When we do this we are speaking of an area that produces approximately eighty per cent of the world's crop, which must be considered also as a semi-luxury, but when we speak of cotton we speak of a commodity for which new uses are continually being found and which has become an absolute necessity for civilized man.

The great danger to the San Joaquin Valley is not that it will produce too much cotton, but in the temptation, which always comes in periods of peak prices, to develop a one-crop area. There will come, as there comes to all agricultural producers, a year when the cotton grower raising cotton on a large scale and hiring labor for its production will not be able to make both ends meet. But the grower who is growing cotton as a diversification of his other farm activities, and who in all probability will be supplying most of the labor for its production himself, will even in those times be in a position to make money on his cotton.

One often hears talk of 500,000 and 1,000,000 acres of cotton in the San Joaquin Valley. There are, however, at least two reasons why this acreage will undoubtedly never be reached. These two are sufficient no matter what others there may be. There is not the available water nor labor for production on any such scale. Nevertheless the greatest good that can possibly accrue to the San Joaquin Valley from the production of cotton will come only in the exact extent to which we use cotton as

Four stages in the production of cotton. LEFT—Planting the crop. RIGHT—Weighing pickers' cotton in the field.

a diversity factor on San Joaquin Valley ranches.

How Irrigation Figures

Most of the cotton in the San Joaquin Valley has been grown under pump irrigation. Even on ranches where ditch water was available this supply has in most cases been supplemented with pump water. Cotton must have water at the proper time if the best results are to be obtained and it is not advisable to take chances on the source of supply. A survey conducted by the San Joaquin Light and Power Company, Fresno, two years ago to determine the conditions under which this crop was being grown showed the average pumping head to be 77 feet. Last year, however, the development of cotton culture spread to portions of the Valley where the pumping head was lower. It is very doubtful, however, if the average head has been reduced as there was also a considerable increase in acreage in the high head territory in both Fresno and Kern Counties. At the present time the cost of water represents from 5 per cent to 10 per cent of the actual production costs for this crop whether grown with pump or ditch water.

It is very easy to obtain widely divergent figures on the cost of growing cotton in the San Joaquin Valley, and the following estimate of costs was prepared by checking up the various individual items and then using the highest unit costs furnished by growers. For example, allowance was made for 2½ acre-feet of water, while the amount of water applied in average soils is only 2 acre-feet. At the cost included, this water was figured against a 77-foot head, when the average head for the Valley is approximately 35 feet. Allowance was made for 2 cents per pound for picking, and the price paid this year was 1¾ cents. Forty cents per cwt. was allowed for ginning and cotton is being ginned for 30 cents per cwt. Seven dollars per acre was allowed for chopping or thinning the crop, when the average will be between $4.00 and $5.00. These costs were based on a production of 1200 pounds of seed cotton, or approximately ¾ of a bale per acre, which would make 375 pounds of lint and 825 pounds of seed. This gives a production cost of $60.55 per acre. Subtracting the value of the seed at the average market price of $35.00 a ton, we have a cost of $45.56 for 375 pounds of lint, or approximately 12 cents per pound.

ESTIMATED COST OF COTTON PRODUCTION IN SAN JOAQUIN VALLEY

Preparing and Planting Land		
Irrigation	$2.00	
Plowing & working down	5.00	
Seed	2.00	
Seeding	.55	$ 9.55
Growing the Crop Per Acre		
Chopping and Hoeing	7.00	
Cultivating	6.00	
Irrigating	4.00	17.00
Harvesting and Marketing		
Picking @ 2 cents	24.00	
Hauling	1.50	
Ginning @ 40c per cwt.	4.80	
Bagging and ties	1.75	
Insurance	2.00	34.00
Total		$60.55
825 lb. seed @ $37.00 a ton		14.99
Cost of 375 lb. lint		$45.56

It must be quite apparent to anybody on the outside looking in, that the San Joaquin Valley's newest baby is in a very prosperous condition. This fact is best attested by the rapidity with which facilities for handling this product have grown in the past three years.

There are today in the Valley thirty-two Gins, five Cotton Oil Mills, and two Compresses, which represent, at a very conservative estimate, one and one-half million dollars in permanent buildings and machinery for handling the crop. In view of the fact that practically all of these investments were made by men who have been in the cotton game for years and are thoroughly conversant with the pitfalls and dangers that attend the development of new industries in new localities, it must be con-

Oklahoma is *Waking Up* to Its Conservation Needs

Unique Problems Joined to Big Opportunities in Comprehensive State Program to Serve Flood Control, Drainage and Irrigation

By E. E. BLAKE

Commissioner of Drainage, Irrigation and Reclamation, State of Oklahoma

E. E. BLAKE

INTELLIGENT use of water has been advocated and resented in Oklahoma since 1889. In times of winter dryness, moved by suffering grain crops; in times of summer drought, moved by burning and curling crops, dying trees and scorching pastures it has been advocated. In times of spring floods and autumn torrents, by those whose hopes were insulted, and whose "fertile soil" was thereby slandered, it has been resented.

Nine years were required to get a "water right" law in Oklahoma; twenty-three years were required to get a "water right" allowed. Even then, the law did not make the organization, or financing, of an irrigation district possible; private irrigation was not indulged; co-operative attempts were, as usual, abortive and futile.

Staggering Water Waste

Meantime, each year, there ran from Oklahoma lands probably twenty million acre feet of useful water,—probably as much as has made California glorious, or Utah possible, or Colorado populous. The water, in its going, washed much fertility from the Oklahoma soil and, with it, carried the destruction of property of an average annual value of ten million dollars—reaching an apex of destruction in 1923, when the property loss from floods was over $100,000,000.00, and the life loss equal to the Pueblo flood; and when every means of earthly transportation and communication across the state was destroyed for fifteen days.

This brought the attention of the people of the state to its waters, theretofore largely unnoticed. A study of the rivers of Oklahoma discloses that they are unique, apparently the only ones of their kind. Running in the west on a gradient of many feet, per mile, over a heavy sandy bed, decreasing to a gradient in the east of a few inches per mile over a former rocky and clay bed, they form a section of a parabola down which the accumulating waters of torrential rains of wide area rush with slowing speed and increasing elevation as they go.

Repeated efforts to secure a conservancy district law failed, until the 1923 devastation (occurring when the legislature could see it) urged the passage of an adapted form of Ohio conservancy law that provides for the districting of an entire stream system as a unit and the distribution of the costs to the farthermost reaches to which the benefits may be traced. An appropriation of $50,000.00 was made to investigate, map, and submit proposed conservancy districts, and a Commission was created to look after it, to negotiate interstate compacts looking to the control of interstate streams, the division of the costs, the allotments of benefits, and the apportionment of waters of beneficial uses.

Many streams are the present subject of study. One stream 400 miles long has been developed to a sufficient extent to indicate the possibilities; cities, counties, engineering schools of the university, and the A. & M. College, the railroads, and many public-spirited engineers and citizens aiding in the work.

It is disclosed that about 500,000 acre feet of water outside of that stream channel capacity, in one week destroyed $25,000,000 worth of property, interrupted every railroad, highway, and transmission system in the state. The flood waters swept the entire valley from hills to hills, so no valley control could be had. Restraint looked to be the only solution to be adopted.

Locate Reservoir Sites

Developing this idea, a scout disclosed about 100 possible large reservoir sites which were investigated. Of these, 43 were temporarily adopted and worked out as the most appropriately located, most efficient, and most economical. Two of them were located on the main prongs of the river where it entered the state; the others in tributaries, all being properly spaced throughout a course of four hundred miles so that the uncontrolled waters to be expected from the water-shed should not, in any place, exceed the channel bank capacity.

Two sites called for a diversion where nature had provided easy diversion canals, one capable of 10,000 second feet flow, emptying into storage of 200,000 acre feet, all at a cost of about $8.00 per acre foot. The other diversion is carried 14 miles, largely through natural channels, and cares for 270,000 acre feet, at a cost of less than $8.00 per acre foot.

A safety ratio of 3 to 1 was adopted over the flood requirement of 1923, and a storage control of a million and a half acre-feet of water was contemplated. Dams of earth and rock, with concrete core, extraordinary spillways, and adequate discharge gates, all of the highest type of engineering, were calculated, and the material and work submitted for estimates of cost to fourteen construction engineers experienced throughout the middle west.

Cost Estimated $8 per Acre-Foot

The estimates of the engineers, while differing on specific elements, when aggregated exceeded by only 2 per cent the estimate of the engineer in charge, which showed a probable cost of about $8.00 per acre foot of entire storage capacity contemplated; providing of course the entire 43 suggested sites would thereafter be adopted by the district. The average construction cost per acre-foot of storage was $8.00, or a total of $12,000,000.00 for the entire project, provided of course the district should adopt the entire project.

Under the law, the district may adopt all of it, or any part of it, or change the suggested plans according to their best engineering advice, subject to the approval of the court, after due notice to each person charged, and hearing.

To cover all contingencies unforeseen, overhead, and other expenses, including

calamities, fifty per cent was added, and the announced estimate of $18,000,000 for the one and one-half million acre-feet contemplated storage (or a rate of $12 per acre-foot) was given out. Compared with $50 property destruction by each acre-foot of wild, ravaging water in 1923 alone, this looked economical and advisable, and it was submitted with the explanation that the district, when organized, could utilize that plan, or any part of it, or any modification of it, or any other plan deemed more acceptable by the district authorities. This work-out was only urged as being a provable demonstration that at least one adequate plan was possible and justified the temporary creation of the district for the purpose of more complete investigation and the proving, or disapproving of the engineers' work; that, if verified, it was advisable that the work should be done.

The data, completed and calculated, seemed to prove that this control of this particular stream would protect twenty railroad crossings and affect every railroad in the state; protect the roads, bridges and transportation of eighteen counties; one hundred and ten townships; one hundred and thirty school districts; the water works and parks of five cities; about 800,000 acres of agricultural lands, and about 2,000 town lots, suggesting an increase of taxable value of more than $300,000,000 and a saving of annual average public expenditures to repair flood destruction of several million dollars. This would afford protection to the state, and its municipalities and administrations, to the state and federal highways, to bridges, the transportation of mails, telegraph, telephone, gas, oil, and other public facilities, and would preserve communication and transportation in the state.

Huge Saving May be Effected

The value of property protected, outside of agricultural lands, was estimated at $600,000,000. A board of thirty-eight appraisers from various walks of life (volunteer and unofficial) arrived at an estimate of benefits exceeding $200,000,000, and allotted the estimated cost of $18,000,000 in proper ratio thereto. A study of the results showed that about 50 per cent had been allotted to public municipalities, about 25 per cent to corporate and unlanded properties, and about 25 per cent to the agricultural lands and town lots, which, strange to say, followed closely the actual results as allotted in the Miami, Ohio, conservancy district.

This ended the work of providing for the conservation of the water. Its beneficial uses were next studied. There being a contemplated capacity of 3 to 1 as to requirement in most of the reservoirs (as measured by 1923 flood, whic was the highest known in historic time) it was carefully considered how much of the gross temporary restraint could be safely impounded for other uses. It was finally arrived at that dependable water could be held, without endangering the flood control uses of the reservoir, for over 100,000 acres of irrigable land.

Some estimates assert that 500,000 acres of irrigation could be reached, and assured, within five years of wise and cautious administration.

Oklahoma's Situation Peculiar

In this, many elements peculiar to Oklahoma were considered: climate, normal rainfall of 30 to 40 inches, as disclosed by thirty-one years of observation; the great territorial length covered by the project; the dependable continuous flow of the rivers and creeks; the ease and cheapness of interlacing the separate reservoirs by extension of the main distribution canals; the character of the soil; nature of the crops; and the probable development of desires for use and application of water as experience educated the customers. In this enters a condition apparently peculiar to Oklahoma.

The west half of Oklahoma is a prairie country. The declination of the state is to the southeast, the average fall being about ten feet per mile in a direct line, and the streams generally much below the general surface plane. The land is not horizontally stratified, but has been a vast silt deposit and has what is called a "perpendicular grain." It absorbs water like a lamp wick, and returns it slowly to the surface. This characteristic accounts for the long drouth-resisting power of Oklahoma's crops, and in fact, makes crops possible in spite of the long intense drouths which afflict the state both winter and summer.

It was considered that this would permit the watering of deep-rooted plants like alfalfa, orchards, nuts, etc., at long intervals, probably in the winter alone, saving the summer waters for more superficial crops. This was deduced from experience in certain known instances. Correspondingly, surface crop ground once saturated was calculated to go longer between waterings than under the usual conditions common to irrigation countries.

Drouth-Resistant Plants

In addition, Oklahoma has developed through necessity many semi-arid drouth-resisting crops unknown in irrigated countries and not usually considered by engineers in arid sections. All things considered, it was felt that the irrigation possibilities from this one conservation would run somewhere between 100,000 and 500,000 acres, as far as man is able to contemplate and conjecture unexperienced conditions.

This water could be sold as a water right basis for $30 per acre, which would mean a return to the district (which will own the water) of from three to fifteen million dollars, or a goodly portion of the total cost from this one source. If the water were sold on a service rate of so many dollars per acre per annum, it could reasonably be expected to return from one-half million to two million dollars per annum, assuming a normal rainfall. There are other sources of return from the water, not contemplated herein, as the water could all be released under a control head and could be easily recaptured thereafter in lower basins and re-used. This is due to the unique topography of the country, which, study discloses, affords most unusual and economic possibilities of storage.

Six Million Acre-Feet Held

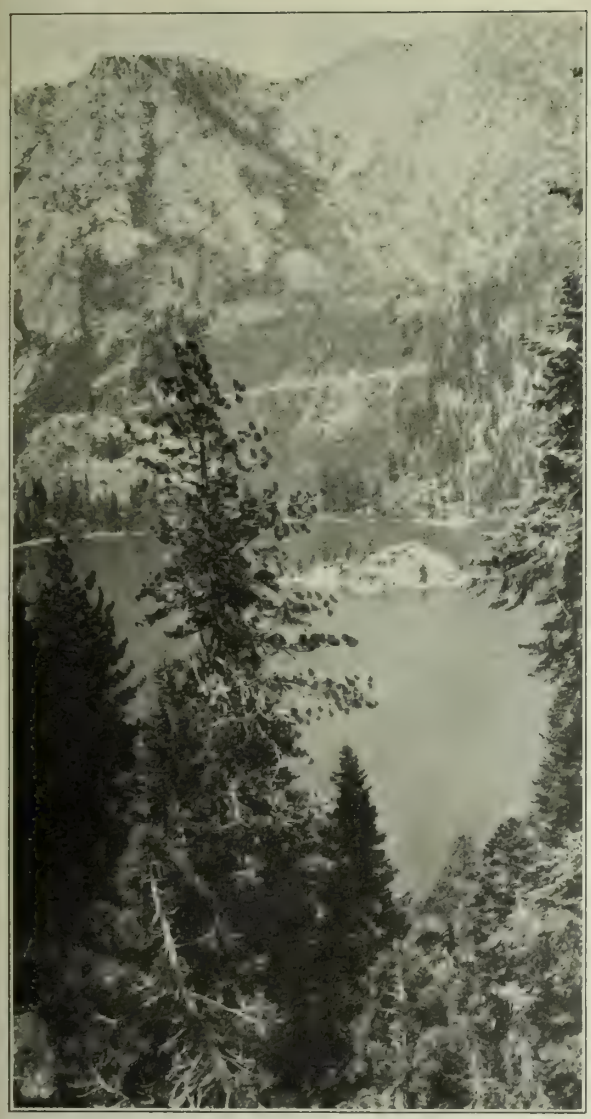
On other streams, investigation discloses that as much as six million acre-feet of water can be held per annum, dependably and with safety for all purposes desired, (for flood and otherwise), at a probable actual cost of about $6.00 per acre-foot for construction. Notably one project, as developed, indicates a two-million acre-feet impoundage of a 149-feet head maximum, with a usable minimum discharge of 6,000 second-feet throughout the year, and this project has a calculated construction cost of $3.00 per acre-foot.

This project also protects from flood, (and could water, after discharge) about 200,000 acres of rich bottom land, which is now frequently ravaged by floods, at present worth only about one-fifth of its estimated worth after protection; and about one-tenth of its worth if it were both protected and watered. This looks advisable. Other projects approach these results, and it might be interesting to know that the highest estimated cost of any so far adopted Oklahoma reservoir is $16.75 per acre-foot.

These projects, as so far partially developed in this, the first year of the Commission's work of gathering material and information, indicates that, at an expense of $36,000,000, or about what the Miami District cost, there could be protected from floods of the river valleys of Oklahoma, approximately two million acres of now damaged or destroyed rich bottom lands, more than a billion dollars' worth of unlanded property, and that such development would (as calculated) make available for various uses six million acre-feet of water, from which at least one million acres of land could be assured of dependable and needed irrigation.

A. S. A. E. Meeting Will *Feature* Reclamation

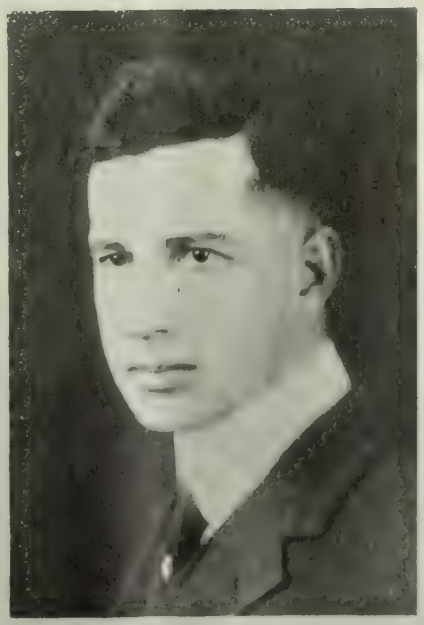
Soils and Soil Moisture Will Be Subjects of Prime Interest at Lake Tahoe Sessions of National Society, June 23-26



Beautiful Lake Tahoe, where the Agricultural Engineers will gather in Annual Meeting late in June.

WHAT reclamation engineers should know about soils, and the relationship of soil moisture and plant growth to irrigation, are to be discussed during the morning of Friday, June 25, at the 20th annual session of the American Society of Agricultural Engineers, in Tahoe Tavern, Lake Tahoe, California. These two subjects and a discussion of the problems of settling reclamation projects will comprise the program of the division of land reclamation.

"A newly insistent demand is being made upon reclamation engineers to possess or acquire a knowledge of soils," according to Major O. V. P. Stout of the Division of Agricultural Engineering, U. S. Department of Agriculture, and Chairman of the Land Reclamation Division of the Society, who will head a symposium on "The Soil and the Engineer."



F. J. VEIHMEYER

Prof. F. J. Veihmeyer, of the Division of Irrigation Investigations and Practice, University of California, will read a paper on "Irrigation in Relation to Soil Moisture and Plant Growth." A paper on selecting, financing, and guiding settlers will be presented by J. V. Mendenhall, President of the Holland Land Company, under the title "Wanted, an Agricultural Engineer." Dr. Elwood Mead, Commissioner of Reclamation of the United States Bureau of Reclamation, will also address the meeting on "A National Reclamation Policy—What it Should Include," and many other engineers prominent in the reclamation and settlement of lands will take part in the discussions.

J. V. MENDENHALL

Major Stout's symposium will give views of authorities on such matters as the nature and extent of the knowledge of soils with which engineers in various phases of land reclamation should equip themselves, where this knowledge can be found, and the circumstances requiring its application.

Professor Veihmeyer's paper will discuss certain phases of the movement of soil moisture, losses of moisture by evaporation from the surface of the soil, and the effect of cultivation on the control of soil moisture. The amount of loss of water by evaporation has been found not to be affected by cultivating the surface in the absence of weed growth, and the distribution of water in the soil likewise is not affected. Some basic conceptions of the relation of soil moisture to plant growth will be presented.

The rate of use of water by plants under different soil-moisture conditions, the wilting of plants, the relationship of soil-moisture to absorption by plants, and the physiological response to different amounts of available soil-moisture are all topics of vital importance in all water requirement, or so-called duty of water studies.

Irrigation Under

A High Degree of Has Been Attained

Island Sugar Industry Depends on Irrigation for its Very Existence

A WORLD rain-fall record of nearly 600 inches for one year comes from the Hawaiian Islands. This excessive rain-fall, however, is in the mountains of the Islands and it does not follow that irrigation is unnecessary. Some of the forty-eight sugar cane plantations, which average three or four thousand acres in area, have an annual rain-fall of only a few inches, although they are within a few miles of the mountains where it is raining almost continuously.

This peculiar situation makes irrigation the logical sequence in the production of crops on the gentle leeward slopes of these magnificent islands. Long ditch systems have been constructed in the mountains to catch the numerous streams and lead them to the plantations. The cost of ditch construction is great, much concrete, tunneling and flume work being generally required. The water is, therefore, costly, and during the past few years the plantation owners have come to realize that this water must be cared for as they would care for their bank accounts if they would avoid wastefulness and obtain maximum crop returns.

Sugar cane is the one outstanding irrigated crop in Hawaii. Altogether there are some 125,000 acres planted to cane, seventy-five per cent of which is irrigated. From 18 to 22 months are required to produce a crop of cane and during this time it is irrigated at seven to twenty-day intervals excepting during the rainy season. Frequently as much as six acre-inches are applied per irrigation and usually not less than four acre-inches are used. A crop of cane may require as many as thirty irrigations and twelve or fifteen acre-feet of water per acre before it is brought to maturity. It is, therefore, evident that the accurate control of the irrigation water, which in some instances is valued at $15 and $18 per acre-foot, is an important issue on the Hawaiian sugar plantations.

Furrow Irrigation

Furrow irrigation of sugar cane is the principal method of field application. It is a combination between the furrow and the contour methods of the States. The cane is planted in nearly level rows 3 feet apart. The furrows between, which are eighteen inches deep, take their supply alternately from ditches running at right angles to the rows, about 100 feet apart. When these furrows are filled with water the furrow gate is closed and the supply diverted into another furrow below. There are variations in the cane furrow application. Sometimes they zig-zag back and forth two or three times when the ground is sufficiently level to allow the water to stand at a uniform depth. Another variation is in the location of gates between furrows to allow the water to pass from furrow to furrow. These are usually in series of eight or ten to permit uniform application.

Overhead irrigation is being tried out by some of the leading plantations. The Hawi Mill Plantation on the northern portion of the Island of Hawaii had about 100 acres under the sprinkler system at the time of the writer's first visit. John Hind, Jr., the manager, was enthusiastic about its success. Although the cost of laying pipes is $150 to $200 per acre Mr. Hind believes it justifiable due to the saving in irrigation labor,

Development in *Hawaii*

RAY J. LYMAN
Tells of Advanced and Progressive Practices

this item being cut to less than one-eighth the former amount required. Other advantages claimed are a 40 per cent saving in water, more uniform application, avoiding loss in field area due to ditches, makes day and night irrigation possible, makes cultivation easier due to absence of deep furrows required by the surface ditch method, and makes fire control very effective during the ripening stages of the cane when the fire hazard is great.

The disadvantages of the overhead system have been the great cost, danger of sprinklers not functioning properly due to trash in the water or heavy winds which blow the water out of its intended area.

Modern Construction

Irrigation construction in general is along modern lines and compares very well with that on the best constructed projects in the States. Some of the plantations have many miles of concrete lined ditches. Lateral diversion and spillway construction is in general like that in the States but frequently distinctive designs are to be seen. The division weirs shown in a picture accompanying this article (page 45) on the Hawaiian Commercial & Maui Agricultural Plantations is representative of the individualistic construction resorted to by the Plantation Engineers who are almost always men from American colleges.

Reservoir sites for the storage of water are scarce but small ones are constructed here and there on some of the plantations to facilitate water distribution. Almost every scheme to be seen in America in the distribution of water is to be found in similar form in connection with irrigation in Hawaii. Steel and wood stave pipe lines, syphons, metal flumes, concrete lined ditches, concrete structures of many descriptions, electric pumping plants equipped with high grade machinery, some of which elevate

water as much as 600 feet from wells to the higher lands, tunnels miles in length to lead the water from the northeast steep wet sides of the mountains to the southwest dry slopes. Millions of dollars have been invested in irrigation development in Hawaii.

Plantation System

On my first visit there I was amazed at what I found and wondered how such progressive development had been brought about. The answer was conspicuously clear after my second visit when I had become somewhat acquainted with the men who manage affairs in the sugar production of these islands. Organization is the keynote throughout the sugar industry here and a daring conservative-progressive spirit prevails in the management of nearly every plantation. The spirit of contest among the plantations is to be observed urging toward better system, better production, better efficiency. It is unfortunate we do not have the incentive for this contest spirit on our projects in the States.

ABOVE—View of pre-cast concrete slab lined ditch on Hawaiian Commercial Plantation, Island of Maui. LOWER—Section of lava rock lined ditch of a type frequently seen in Hawaiian irrigation systems.

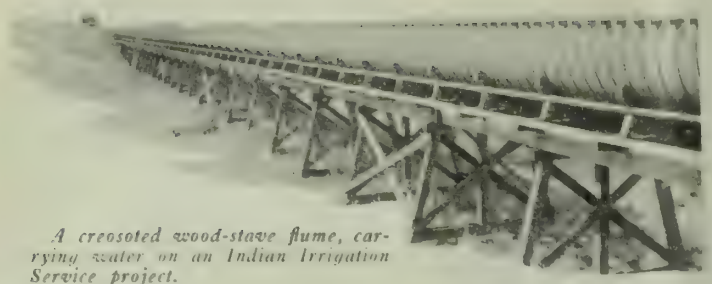
The forty-eight sugar plantations are owned and operated for the most part by five different companies which are more or less inter-related. This organized ownership has been so decidedly business-like that no question has been left undiscussed wherein it involved more efficient production on the plantations. Many years ago an organization of nearly all the plantations under the name of the Hawaiian Sugar Planters Association was created to carry on research in the production of sugar cane. More than forty people constitute the research personnel of this association under the capable management of H. P. Agee. It would probably be reasonable to state that the H. S. P. A. has been responsible for the production of millions of tons of sugar, which would not have been produced had its research work never been done in cane variety improvement and scientific cultivation methods.

Their experiment station located practically within the city limits of Honolulu is a model of neatness and orderly control. A beautiful and spacious building, which is an inspiration to all who visit the station, provides office and filing space for records and specimens as well as an abundance of room for testing equipment and laboratory research along chemical, physical, bacteriological and entomological lines. For thirty years this association has been publishing a quarterly magazine, for its members only, which serves as a distributor of a veritable stream of knowledge useful to the plantation operators.

Water Measurement

The Ewa Plantation on the island of Oahu, 20 miles from Honolulu, embracing about 7500 acres, differs from most of the plantations in its water supply. It depends entirely on wells from which there is pumped 100 to 175 sec. ft. for 9 or 10 months of the year by means of electricity generated in Hono-

(*Continued on Page 45*)



A creosoted wood-stave flume, carrying water on an Indian Irrigation Service project.

The *Indian* is Practical Irrigation

With Uncle Sam as His Teacher

Results Attained by Indian Irrigation Service Admittedly Not Ideal, But Worth While from Many Standpoints

WHEN federal reclamation is mentioned one thinks at once of the U. S. Bureau of Reclamation, which came into existence in 1902. That branch of the government, however, notwithstanding the importance which its irrigation activities have assumed, was not the first to construct irrigation projects. In the year 1867, considerable work was done on the Colorado River Indian Reservation by the U. S. Indian Service and has been continued at irregular intervals from that time on.

In 1904 the project on the Crow Indian Reservation, the first large project to be undertaken in the interest of the Indians, was begun.

The first work was done with a dual object—not only to provide water for irrigation, but to teach the Indians how to work.

Growth of Organization

There was not much of an organization in the earlier days, but an engineer was hired to supervise the work. Later, an Inspector of Irrigation, who was an irrigation engineer, was placed in charge of the work.

About 1902, W. H. Code, now of the engineering firm of Quinton, Code and Hill, Los Angeles, was made chief engineer of the Indian Irrigation Service, and held the position until about 1911. Under his supervision the organization was efficiently built up to handle the work on the various reservations, where the work was under the immediate charge of a Superintendent of Irrigation.

In 1912 the five Superintendents of Irrigation were given special districts. This practice has been continued to date, and the work in each of the five districts is under a supervising engineer who is responsible to the Chief Engineer and the Commissioner of Indian Affairs.

Since the irrigation work was first initiated in the Indian Service, some 170 different projects have been constructed or are now under construction or are waiting for funds. Many of these are very small, like the Mission reservations in California and the various pueblos in New Mexico.

Spend Thirty-Two Millions

The total expenditures made in the surveys and construction, up to June 30, 1925, amounted to $25,287,000 and $7,461,400 had been expended on maintenance and operation.

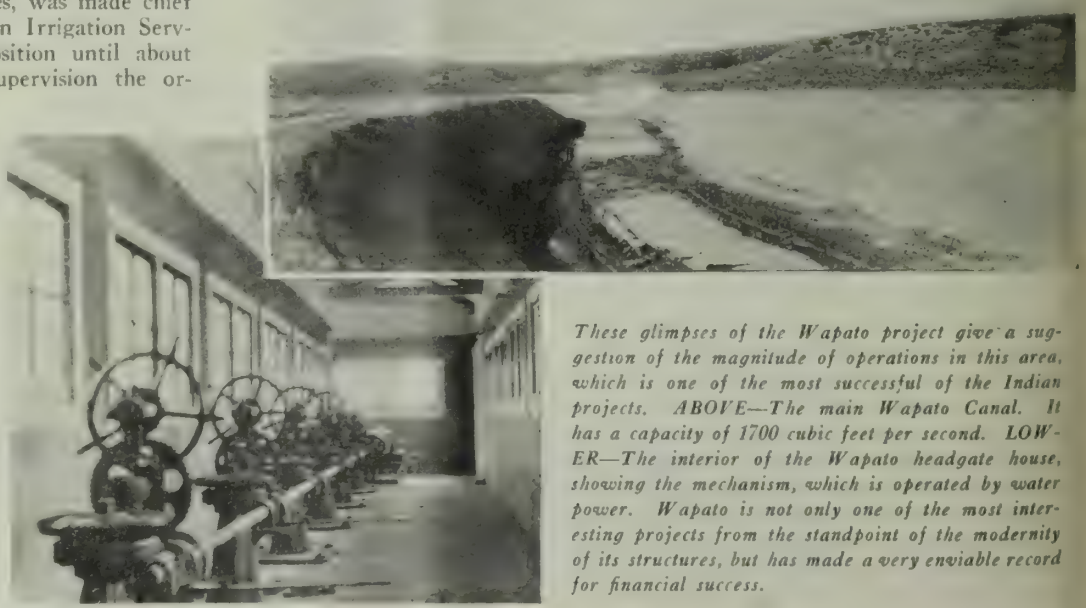
The total area brought under canals by that expenditure is 657,100 acres. There remains some 711,000 acres in projects surveyed and found feasible, yet to be constructed at an estimated cost of $27,351,000. These figures are taken from the hearing before the subcommittee of the House Committee on Appropriations.

There were many interesting sights when the Indians first began to build ditches. It was a significant and yet an amusing spectacle to watch a young brave driving a team of Indian ponies on a slip scraper with one hand and holding a blanket around himself with the other hand, with his long hair flapping in the breeze.

The government has no doubt increased the value of the Indian lands by the expenditure thus far made by at least three dollars for every dollar expended.

Reasons for Disappointment

There are many reasons why the Indians have not done as well as some of us expected. While the results, viewed from the standpoint of ideal accomplishment, may have been disappointing, there is still much to record on the credit side of the ledger. We should appreciate these facts:



These glimpses of the Wapato project give a suggestion of the magnitude of operations in this area, which is one of the most successful of the Indian projects. ABOVE—The main Wapato Canal. It has a capacity of 1700 cubic feet per second. LOWER—The interior of the Wapato headgate house, showing the mechanism, which is operated by water power. Wapato is not only one of the most interesting projects from the standpoint of the modernity of its structures, but has made a very enviable record for financial success.

Learning Farming

UPPER—The Wapato Dam during the course of construction. LOWER—Where a power house will translate falling water into kilowatts—the by-pass at Power Drop No. 1, Wapato Project. Here 1200 cubic feet of water fall every second a distance of 21 feet. The power house will be located at the right.

1. We often expect too much of an Indian in the way of improvement of his allotment. It takes considerable capital

L. M. HOLT

to construct the necessary building and fences and to clear and level the land for irrigation.

2. The construction on many of the projects has been so slow that many owners have died and as a consequence we have the deceased Indian allotments. These are usually the first ones to be sold to white people.

3. In many cases allotments were made to women and children, and these have usually been leased to white farmers under what are known as "improvement leases," and after three to five years these leases have brought good rentals to their respective owners.

One of the outstanding projects, and one that the writer has been connected with for the past thirteen years, is the Wapato Project on the Yakima Indian Reservation in the wonderfully productive Yakima Valley, Washington, where soil, climate and water for irrigation, are eminently satisfactory, and conducive for success for white man and red man alike.

A large part of the inherited lands have passed into white ownership at good prices to the heirs. These and the rented Indian lands have been examples to the Indians, and while they are not farming in such large numbers as we had hoped, nor quite in the manner that we had planned, there are many very good farmers among them. About 500 are farming themselves and 1500 more are receiving benefit by leasing their lands.

This project, when completed, will irrigate 120,000 acres of allotted land. Last season, with less than 80,000 acres irrigated, it produced a crop valued at $8,000,000.00.

This project is interesting in other ways. The estimated cost is $50.00 per acre, including drainage and storage water for part of each allotment. The drainage canals were constructed at the same time the canals and main laterals were built and often the two were built with one operation by the use of dragline excavators.

Wapato Is Self-Supporting

This project is also interesting for the reason that even in its incomplete state it has been self-supporting for several years and has had no farmers, either Indians or whites, who have become delinquent in the payment of maintenance and operation charges; and, according to the report contained in the "Hearings before Congress" mentioned in the foregoing, it has reimbursed more of the construction charges than all the other Indian projects combined. This in itself is an enviable record for any irrigation project.

The demand for land on this project has, with the exception of 1922, 1923 and 1924, always been in excess of our facilities for supplying irrigation water, due to lack of funds for construction.

Great Transition Required

On many of the reservations the Indians have had to change from stock raising and various other industries to an agricultural mode of life, and their progress has naturally in many instances been very slow, because of the enforced transition.

There were many instances, years ago, where the Government was criticised for not protecting water from reservation streams or boundary streams for its Indian wards. Today there is less room for such criticism, for considerable work has been done to protect these waters by construction and beneficial use.

Taking everything into consideration, including such factors as the length of time construction has been under way, the work accomplished in protection of the waters for the Indians where parts of the reservation have been thrown open, and the increased value of the Indian lands, as the result of the service's work, the results obtained seem to justify the expenditures made.

Ground-Water Studies Should Pave Way for Developments

Services of Expert on Sub-Surface Conditions Will Make Success Surer for Practically Any Water Project

By HYDE FORBES

PART II

THE FIELD for the trained ground-water hydrologist is ever widening. For example, industrial processes in metropolitan areas frequently require water in excess of that which can readily and economically be obtained from the municipality. In such cases it may prove invaluable to be able to obtain water, of sufficient quantity and desirable quality, from wells on a property designated as a factory site. It is therefore incumbent upon the owner of such a tract to have an investigation made and a report prepared dealing with this advantage if he wishes to make a sale. The knowledge that such water is available enhances the value of the property. Similar reports are of value in the case of the projected sale of suburban estates, for residence purposes, which are not supplied by municipal water systems.

In the case of agricultural land in the West the available water supply is the all-important factor. Many irrigation enterprises and municipal and domestic supplies are dependent wholly upon ground-water developments, and some of the largest of such enterprises depend in large part upon ground-water supplies. Future projects will depend more and more upon such sources. The reclamation of swamp and overflow lands is essentially a problem in ground-water hydrology, as is the drainage of irrigated areas, and so on over an ever widening field. Hydrologists are frequently called upon by banks and bond houses to investigate and report upon the available ground-water supply for tracts or areas upon which mortgages are sought or bond issues are expected to be sold for the purpose of funding agricultural development.

Reservoir Losses

Another application of ground-water hydrology is its relation to the probable loss of impounded water from a reservoir site through seepage and ground-water drainage. Costly errors have often been made by engineers who have advised the acquisition of reservoir sites, and have constructed dams only to find that the impounded water escapes underground. A knowledge of the geology of the reservoir site, the detection of the presence of aquifers of high permeability, and the application of the principles of ground-water movement, would have forestalled many such financial losses. Reservoir sites have been selected which presented perfect dam sites, large capacity for low dam heights, and other elements looked for by the engineer, but which the ground-water hydrologist would necessarily abandon because of factors which would allow unreasonably large seepage loss.

As the work of the ground-water hydrologist becomes wider-spread and his advice more generally accepted with confidence by engineers, it will be found that in nearly every problem in water supply, irrigation, and drainage, a primary investigation may indicate precautionary steps to prevent damaging modifications of ground-water conditions. If there be a choice of development plans, the one most favorable to low financial or other losses can be recommended.

Geologic Structure Important

Let us continue the consideration of the impounding of surface waters. Numerous examples of high efficiency (in that a large percentage of the water entering a reservoir is available for use) can be cited where a reservoir site is composed of granite, shale, natural sinks which have been covered over by the precipitation of fine material and cemented through concentration and precipitation of soluble salts through evaporation of the surface waters, etc.; while serious losses, of as high as 75 to 90 per cent, have been found to exist at reservoir sites composed of lava beds with strata of tuff or cinder interbedded, alluvial materials, soil coverings with sandy or gravelly substratum, etc.

The geologic structure is an exceptionally important feature of reservoir and dam sites. Where the stratification dips away from the reservoir site toward a drainage line in an adjoining watershed, the added hydrostatic head will cause serious excess seepage which, with the mechanical work of the percolating water opening larger passages, will increase in volume rather than decrease. In some cases "dikes," which mark especially good dam sites and are generally considered as blocking subsurface movement, may provide a face for ground-water to follow, under the added pressure head, into an adjoining waterway. Fault lines are the most important structural features. If they pass through or in close proximity to a dam site, a rigid masonry or concrete structure would be weakened or completely destroyed by any crustal movement along the line of weakness. If they pass through a reservoir site, they are lines of weakness along which ground-water might readily percolate, under head, into an adjoining water-shed.

May Damage Adjoining Lands

The impounding of surface water may result in raising the water level to heights detrimental to nearby lands. In such cases the principle of law involved generally results in an action for damages. In case the cause of the water level rise is disputed, the ground-water hydrologist may be called upon to investigate and report to the court the nature, extent, and results of the modification.

In the semi-arid regions of the western states, actions have frequently arisen from the impounding of surface water of streams which, in a natural state, would have supplied ground-water through seepage to lands favorably situated lower along the stream course. In such instances the values involved have been large and justified exhaustive investigation, not only of natural and modified ground-water conditions over the affected area, but of the natural and modified seepage due to the proposed or effected ponding of the surface water and the relations of the natural and resultant seepage to former and future ground-water conditions. The use of the impounded water, use of ground-water, and other elements enter into such problems, as the question is largely one of economics. It is the usual policy of the courts that water which would otherwise be wasted should be conserved and used for economic development, but the owner of a vested right in a portion of the water should not be deprived without compensation of such water as he can put to a beneficial use upon his land.

Wells Involve Problems

The effect of ground-water developments through wells has presented a variety of problems, both to the courts and those responsible for their projection. In the case of interference in the correlative rights between two wells or groups of wells drawing upon a common ground-water supply, but owned by different parties, it may be that the additional development complained of will increase the rate of discharge over the rate

(*Continued on Page 27*)

Four More Key Men Who Are Members of Editorial Board

These Construction and Equipment Leaders of Irrigation Industry Serve as Counsellors to MODERN IRRIGATION

ARTHUR BENT

SOME thirty leaders in various forms of irrigation activity have been introduced, from time to time during the past year, as members of the Board of Editorial Advisors of MODERN IRRIGATION. Representing agriculture, conservation, management, engineering, and other departments which go to make up the balanced and diversified industry comprehended by the general term "irrigation," these men constitute probably the most impressive group of leaders ever united in the support of a similar enterprise.

Two very important divisions of the Editorial Board, representing key departments of irrigation progress, are the groups made up of prominent men from the Construction and Equipment branches of the industry.

These two groups include eight members, well known wherever irrigation structures are built or irrigation equipment is used.

ARTHUR S. BENT

Arthur S. Bent, president of the Los Angeles Chamber of Commerce, vice-president of the Chamber of Commerce of the United States, and president of Bent Brothers, builders of some of the west's largest and most famous dams, is a man who has distinguished himself in a number of lines, but is probably best known for his eminence in work connected with the construction of large irrigation structures. Mr. Bent was born in 1863 in a tiny frontier settlement, on the Nevada-California boundary line, in Sierra County, California. When he was seven years old, he came with his parents to Los Angeles, and when a young man decided to become a construction contractor.

A short experience in the business, however, discovered to him that successful contractors must have the services of competent civil engineers at their command, and so, with characteristic decision, he underwent the training that made him an engineer—and one of real ability.

K. E. VAN KURAN

With the growth of the irrigation industry in the west Mr. Bent and his organization assumed a place of leadership in the building of great dams, the most recent of which to be erected by them is the great Exchequer Dam of the Merced Irrigation District. He has been active, also, in the work of various civic organizations, recently resigning after notable service as a member of the Board of Education of Los Angeles. He was elected president of the Los Angeles Chamber of Commerce, the largest and most active commercial body of its kind in the world, early in 1926, and was recently chosen a vice-president of the Chamber of Commerce of the United States. He has been president of the Associated General Conutractors of the United States, and has held membership and official positions in numerous other technical and professional organizations.

C. C. THOMAS

C. C. Thomas holds a high place in the fields of engineering design and construction both for his own wide experience and learning, and his connection with a firm which is, in a sense, both a national and an international institution, Dwight P. Robinson & Company, Inc.

He was born in Detroit in 1872, and educated at Leland Stanford University and Cornell University, receiving the degree of Mechanical Engineer from the latter institution. His early experience was gained as a draftsman with eastern concerns, in which he became successively assistant engineer and chief engineer.

From 1901 to 1903 he taught in New York University as professor of marine engineering and naval architecture; and during the succeeding seventeen years he held important professorial posts in various leading universities of the country, including: assistant professor of mechanical engineering, University of California; professor of marine engineering, Cornell University; professor of steam engineering, University of Wisconsin; professor of mechanical engineering, Johns Hopkins University.

Vol. II JUNE, 1926 No. 6

A Prophet of Success

THIS INDUSTRY of irrigation has its optimists and its pessimists, like every other division of mankind's activity. Neither one—possibly—sees always a true picture of water development; both are sincere, however, in their attempt to interpret the phenomena they see. In the midst of certain prophecies of doom, it is a relief and an encouragement to hear one strong and influential voice ever uplifted in the praise of what irrigation has accomplished, and confident predictions of its continued triumph.

J. Rupert Mason is one of those who feels strongly on the subject of the future of irrigation, and whose faith is not unsupported by good works. As head of the financial house of J. R. Mason & Company, he demonstrates his belief in a very tangible way, and by virtue of his comprehensive knowledge of irrigation matters, his words are attended with respect by the entire industry. This is what Mr. Mason has to say about the current outlook for irrigation:

"We are now witnessing one of the greatest movements toward irrigated agricultural lands ever known. The last year of subnormal rainfall once again reminded orchardists and farm owners of the South and West that irrigation is the most inexpensive and desirable crop insurance obtainable.

"I confidently predict that 1926 will prove the most active year we have ever witnessed, particularly in the great San Joaquin valley, Imperial and Palo Verde valleys of California, the Salt River valley of Arizona and the lower Rio Grande valley of Texas.

"This great activity will not alone be confined to the present increased demand for good land with dependable irrigation water, but will also be reflected through every ramification of the business and banking interests of the irrigated Southwest and West.

"The farmer, the city wage-earner, the banker, the merchant and the professional man—in fact every phase of human endeavor—is certain to feel the present forward trend, as it spreads over our fertile irrigated farms and orchards, where crop failures are unknown.

"Already hundreds of automomiles loaded with tourists, newcomers and their families from all points of the compass are arriving. Railroads also report tremendously increased travel through these sections. Countless millions of new dollars are now pouring into western banks from the sale of the enormous variety and quantity of fruit, vegetables and dairy products, made possible through irrigation.

"It is very significant that since the post-war depression, there have been almost no bank failures in any irrigated section.

"A personal visit to any of the valleys mentioned would disclose a story of well-being, independence and contentment attained in substantial, comfortable homes, amid pleasant surroundings and progressive neighbors.

"The financial stability of all irrigation districts in these valleys, under every test, not one of them having been delinquent for even one day in meeting any of their obligations, together with their present prosperity and steady growth, have set the one-crop and dry-farming sections agog with amazement, and far greater development and growth is confidently forecasted during the present year."

How's Business?

A FRIEND of ours, whose impressions of the irrigation industry are derived, very largely, through the sale of pumps and other equipment, told us the other day that his business had "slowed down considerably." Then he went on to elaborate his more or less pathetic tale of inactivity and sales resistance met in the field.

Yes, good friend, possibly present conditions in your particular branch of this great industry—the sale of pumps and kindred supplies—are not so good today as they were three months ago. Doubtless it is puzzling and discouraging to you, after bountiful rains and assurances of a "good year" had brought a general feeling of optimism, to find that your prospective customers are delaying their purchases and that sales records

POINT *Of* VIEW

Look the situation over from the farmers' standpoint, however, and you will get a different interpretation of the significance of today's slack demand. You will see, upon further analysis, that it is only an augury of better things for tomorrow.

The irrigation farmers of those sections where the 1926 rains have meant most, and were most needed, have been through a protracted period of water deficiency. They have learned, to their cost and sorrow, the need of making ample provision for a reliable and independent supply of water in times of natural shortage. That lesson will not soon be forgotten.

But at the same time that the farmers were learning these lessons, they were going through experiences and making financial sacrifices that would naturally prevent them from immediately putting into practice the salutary moral which the shortage brought home. In other words, Farmer Jones may have learned that he can not safely be without ample pumping equipment—but in the process he has not kept enough money to buy the equipment that he *knows he needs.* He is living today on the scanty returns, perhaps, of last year's crop. He sees evidences of a year of ample water supply, and is delaying the purchase of a pump until the need is greater and the pocket-book a little heavier.

So, good friend of the pump, don't be too much alarmed. The farmer who has come through the long dry period is not going to forget the need of the pump, if you do your duty in reminding him of it. He is only delaying his purchase.

Schools vs. Pumps

PERHAPS these farmer friends of yours are like the farmers living in a certain rural school district up in Ventura County in California—known as the "Briggs" district. For the past three years these prosperous farmers have been looking forward to having a new school. But each year they looked in vain for promises of plenty of water, and when the water came not, they were a little timid about making large expenditures for schools and similar luxuries.

And so they worried along for three years, each year planning the new building for the following season, and each following season deciding to retrench and wait conservatively until prospects looked a little better and a "dry year" appeared less imminent.

But this spring the rains fell, and on May 31 they had their exercises in the new school building, a beautiful, permanent structure that would grace any metropolis. This is the sort of thing that is happening all over the irrigation country—but perhaps these farmers are the very ones who are delaying their equipment purchases until later in the year. Perhaps the reluctance to buy pumps at this time means simply that they prefer schools and need them most—the pumps will come later.

And On the Other Hand

FROM OTHER sources there come reports of the most optimistic tenor regarding the business outlook in the irrigation field for the present and immediate future. One man, whose business is the sale of drilling rigs, says that things have never looked brighter, that the rains and higher water-table have stimulated irrigators to go down and get the water while it is there and that his equipment is meeting a steadily increasing demand. Several pump companies, whose business is not limited to California but is interstate and international in its extent, report larger sales, double shifts, expansion in factory space, and a margin of unfilled orders beyond capacity of production.

And, so, viewed from the standpoint of the industry as a whole there is little ground for a despondent view, and much reason for encouragement. In a few cases the lesson of the dry years was so expensive that equipment purchases must be longer deferred through necessity, but, in the main, the results will be a quickening of demand for the equipment that means insurance against unexpected drouth.

Politics vs. Policies

THE ACCUSATION has been made that partisan politics has begun to show its sinister influence in the matter of the Boulder Canyon Project Bill. When the House committee on irrigation and reclamation voted to delay consideration until after the congressional recess, there was apparent an alignment of influence along party lines. It was said that Representative Hayden feared to go back to his home state, Arizona, with the approval of the Boulder Canyon project as one of the last recorded achievements of his committee, for he must face an election there before Congress again convenes. Therefore he moved for delay, and he was supported without exception by his Democratic colleagues.

The whole course of the projected development of the Colorado River has been so hedged about by political considerations of one kind or another that it would seem that it might be spared the evil of party division, which will surely becloud the real issues involved.

The fact, however, remains that the problem of the Colorado River and its development is not a partisan issue. It is no more partisan than the river itself is Democratic or Republican. It is no more partisan than the great southwest is the exclusive charge of one party or the other. There are problems yet to be decided about the Boulder Canyon project; there are issues of fact and issues of policy, and these must be resolved; but there are no issues of politics, and the man who would surround the problem by questions of political expediency is creating fictitious obstacles that will embarrass an early and wise settlement.

Four Members of Advisory Board

(*Continued from Page 21*)

Since 1920 he has been western representative of Dwight P. Robinson & Company, Inc., with offices in Los Angeles. He is vice-president of the organization. He is a member of various technical societies, and author of a standard work of steam turbines.

A Leader in Electrical World

K. E. Van Kuran is a western product, born in Laramie, Wyoming in 1882, and brought up and educated in Oregon and Washington. His high school education was received in Portland and his higher training in the University of Washington at Seattle.

He entered college in 1900 with the purpose of becoming an electrical engineer, and gained valuable experience even as an undergraduate by working during vacations in the various electrical departments of the Seattle Electric Railway. He was graduated with the degree of Bachelor of Science in Electrical Engineering and a distinguished athletic record which included two years as captain of the crew.

Upon graduation, he immediately entered the Westinghouse Electric and Manufacturing Company as a college apprentice, and at the end of two years apprenticeship became a member of the headquarters sales department, occupying various sales engineering positions of responsibility.

In the fall of 1911 he came to the Los Angeles district office of his company as assistant district manager and was appointed district manager in 1915, which position he has occupied continuously since that date.

His usefulness as a citizen of Southern California is not limited to his service to his company, however, as he has held numerous positions of responsibility in various civic and professional organizations, including the Electric Club, the California Electric Bureau, Pacific Coast Electrical Association, and important committees of the Los Angeles Chamber of Commerce.

An Equipment Executive

S. F. Forbes occupies a unique position in the irrigation equipment field of the west. For the past nine years he has been Pacific Coast manager of Fairbanks, Morse & Company, a concern whose products have been synonymous with irrigation developments in this country for the last generation, in charge of all United States territory west of the Rockies, including Alaska, Hawaiian Islands and the west coast of Mexico.

It is perhaps not an overstatement to rect distributors of the company's own products or as jobbers for other manufacturers, fully fifty per cent are sold to the irrigation and its allied fields. Mr. Forbes has, therefore, had exceptional opportunity to visualize what irrigation, insay that, of all the varied lines carried by the Pacific Coast branches of Fairbanks, Morse & Company, either as di-

C. C. THOMAS

cluding water developments of every kind, means to the whole western half of the United States, as well as to the success and prosperity of the company with which he is associated.

His experience has differed radically from that of many members of the Board, having been predominantly a business experience, which has brought him into an understanding contact with the commercial and financial phases of irrigation as well as the many other industries served by his company in the world-wide field.

After a varied connection with large eastern corporations, as a young man, particularly in the business departments of some of the greatest railroads in the country, Mr. Forbes came to Fairbanks, Morse & Company twenty-one years ago, and has been, successively, purchasing agent, general manager of railroad sales, district sales manager in the eastern territory, manager of thee company's Los Angeles branch, and Pacific Coast manager.

As regional head of a company in such direct touch with agriculture and irrigation as that which he serves, and so largely dependent upon general conditions of prosperity, brought about by the intelligent application of water to the lands of the west, Mr. Forbes has a lively appreciation of the significance and problems of irrigation, and is one of its most earnest and influential leaders.

Work Approves Contracts for Owyhee Project

Drafts of contracts proposed to be entered into between the United States Government and three irrigation districts on the Owyhee reclamation project in Oregon were approved late in May the Interior Hubert Work.

The districts are the Owyhee Irrigation District and Slide Irrigation District, both in Oregon, and the Gem Irrigation District, Idaho. Under the forms of contract, all of which are similar in terms, each district agrees to pay its proportionate part of the construction cost of the project in 39 annual instalments, the first five instalments of which may be smaller than the remaining 34.

Execution of the contracts providing for the repayment of the entire construction costs of the project to the Government must be made with the various irrigation districts before actual construction is started by the Bureau of Reclamation. The Interior Department appropriation act for the fiscal year of 1927 makes available the unexpected balance of $315,000 of a previous appropriation to commence construction of this project. The total estimated cost of the Owyhee project when completed is $18,000,000.

Hits Brush Burning as Method of Increasing Run-Off

The fatuousness and fatal results of attempting to increase run-off of surface water by burning off brush cover was dealt with without gloves by George S. Hinckley, city engineer of Redlands, California, speaking at Riverside in May before the local chapter of the American Association of Engineers. Water conservation and storage were discussed by Mr. Hinckley, who pointed out the need of reforestation both from a local and national standpoint.

The speaker showed charts of burned-over areas in the west, and pointed out that it was easier to get money to fight forest fires than to prevent them, when the prevention is the more important thing. Comparing the utility of storage in reservoirs with underground storage in gravel beds, Mr. Hinckley asserted that the gravel bed method was not only cheaper but more efficient.

THE HYDRAULIC DIGEST

A Monthly Bulletin Board of Brief Facts and Events from Far and Near

Haugen Bill Defeated

The Haugen bill, providing for price stabilization by the government in the interest of the producer of farm crops, was defeated in the House of Representatives by a vote of 212 to 167 on May 21.

Water Election July 1

Voters of Morro water district, San Luis Obispo County, California, will go to the polls July 1 to ballot on the issuance of $35,000 in serial bonds to provide funds for the construction of a water system for the district.

Vale Project Gets Contract

A contract has been submitted to the Vale (Oregon) Irrigation District by the Interior Department, providing a basis for the continuance of operations, with a provision for repayment by project settlers over a period of forty years.

Discuss 10,000 Acre Project

Land owners of College City, Colusa County, California, are considering a project to bring water a distance of ten miles from the canal of the Glenn-Colusa Irrigation District to irrigate 10,000 acres in the neighborhood of College City.

Chelan District Approved

Organization of the Chelan River (Washington) Irrigation District has been approved by the county commissioners having jurisdiction. Four hundred acres are to be included in the district, and the cost of development is estimated at $40,000.

Vote to Accept Contract

Land owners of the Hermiston (Oregon) Irrigation District have voted to accept the contract offered by the federal government to govern the relations between the settlers and the Interior Department. The contract calls for the district to take over its own affairs on December 31, 1926, and to become responsible for its operation and maintenance.

Santa Ynez System Agitated

Residents of the Santa Ynez valley, Santa Barbara County, (Calif.) are once more interested in a project to create an irrigation district and build a series of dams in the valley. H. H. Henderson, an engineer, is the father of the idea.

Wants Mokelumne Water

Stockton, California, through its mayor, has made a move toward the creation of an adequate municipal water supply, in filing with the state Division of Water Rights application for permit to appropriate sixty second feet from the flow of the Mokelumne River, which would give the city a supply of 38,000,000 gallons daily.

Ask Receiver for Project

Application for a receiver has been filed in the Superior Court at Walla Walla, Washington, for Irrigation District No. 4, embracing the Burbank project, which has been in financial straits for some time past. The district includes 9,000 irrigable acres, and was organized in 1920. Reorganization may follow the appointment of a receiver.

Big Run-off in Lake Hodges

Lake Hodges, San Diego County, California, an important source of water for irrigation and domestic use to various parts of the county, has impounded a total of 10,500,000 gallons of water during the present season, according to figures of the San Diego city water department, which recently acquired the lake from the San Dieguito Water Company.

Senator Stanfield Beaten

Robert N. Stanfield, who has served as United States senator from Oregon since 1921, was defeated for the Republican nomination as a candidate to succeed himself in the elections held May 21. Frederick Steiwer, attorney and wheat grower of Pendleton, won over Senator Stanfield as the Republican nominee, and Bert E. Haney was the Democratic choice.

Vote $19,000 Bonds

Citizens of Ramona, San Diego County, California, on May 4 voted $19,000 in bonds for the establishment of a water district comprising 600 acres of land surrounding and including the town of Ramona. The water will be used for irrigation and to supply domestic needs as well, and will be drawn by pumps from the Santa Maria River. The vote was 98 to 2.

Will Survey Ochoco District

Oregon Agricultural College is to undertake an economic survey of the Ochoco (Oregon) Irrigation district, its extension department co-operating with the office of Rhea Luper, state engineer, it has been announced. The projected survey, which will be completed in July, it is anticipated, will constitute the first step toward a plan for solving some of the district's financial problems.

Offer Sale of Water Rights

The Stockton and Mokelumne Canal Company has offered to sell its canal system and water rights to the Woodbridge Irrigation District (California) for $250,000. The offer was made with the provision that it was for immediate acceptance, and that it should not cause delay to the pending application of the company for permission to abandon public utility service or to increase its water rates.

Palo Verde Growing

When sufficient irrigation water is available, 90,000 acres of land in the Palo Verde Valley, California, will be open for farming, it is declared by Myron M. Winslow, Riverside County farm advisor, after a survey of the valley's resources. Forty thousand acres, two thousand of which have been added in the past year, are now under cultivation. Cotton acreage amounts to 22,000 acres, alfalfa 7,000 acres, and vineyards 800 acres. The valley will depend on the Colorado River for further irrigation development.

HYDRAULIC ENGINEERING

Dealing with the Practical Problems of the Operating and the Consulting Engineer

MULTIPLE-DOME TYPE APPROVED FOR COOLIDGE DAM

FINAL steps toward commencement of construction of the Coolidge Dam on the San Carlos Indian irrigation project in Arizona were initiated May 10, when Secretary Work of the Interior Department approved a special report of the Board of Consulting Engineers recently appointed to pass on plans and specifications for this structure.

This board was composed of Major General William C. Langfitt and A. J. Wiley, consulting engineer, who have just completed an investigation of the dam site across the Gila River after which they prepared their report. With the adoption of the board's recommendations action is expected to be taken promptly in advertising for bids and awarding a contract.

In its special report the consulting engineers recommended approval of plans for the type of structure known as the "Multiple Dome Dam," estimated to cost $2,836,000. Except for minor modifications they also recommend that the plans for the dam as drawn up by the Assistant Chief Engineer of the Bureau of Indian Affairs and later approved by the Chief Engineer be definitely adopted.

Los Angeles Men Consultants

The plans for this dam were prepared in the Los Angeles office of the U. S. Indian Service under the direction of Major C. R. Olberg, Assistant Chief Engineer, Indian Irrigation Service. Louis C. Hill and Fred A. Noetzli, Consulting Engineers, Los Angeles, California, were appointed a year ago by the Commissioner of Indian Affairs to supervise plans and construction of the dam.

Designs were made for dams of the gravity type, arch, multiple arch, multiple dome and rock-fill type. In a report of last November to the Commissioner of Indian Affairs, the consulting engineers, Louis C. Hill and Fred A. Noetzli, recommended that bids be asked for the construction of dams of the gravity, multiple arch and multiple dome type, the final selection of the type of dam to be constructed to be made after receiving bids from contractors.

Recently, the Commissioner of Indian Affairs recommended to Congress the construction of the multiple-dome type of dam. The Secretary of the Interior appointed Major General W. C. Langfitt and A. J. Wiley to review the plans of the dome type and final approval by this board was given, followed by similar action by the Secretary on May 10.

Power Storage Feature

The report of the consulting board calls special attention to the fact that the construction of the dam and its use as a storage reservoir for irrigation will permit the generation of useful electrical power which will find an established market at profitable rates. It recommends that the necessary and mechanical appliances and machinery for this purpose be installed as part of the construction, also pointing out that the additional cost will not be great and the sale of power will relieve materially the operation and maintenance charges to the water users.

The construction of the project will make possible the irrigation of between 75,000 and 100,000 acres of land, about one-half of which will be lands of the Pima Indians, in the Gila River Indian Reservation, near Sacaton. The site of the dam is the Box Canyon of the Gila River, near the junction of the Gila and the San Carlos, about 50 miles above Florence.

The dam will create a reservoir the storage capacity of which will be approximately 1,200,000 acre-feet, and the annual average run-off at this point is approximately 400,000 acre-feet.

The height of the dam, from river-bed to the top of the structure, will be 220 feet, the height from river-bed to spill-way crest 200 feet, and the spillway gates will have a height of ten feet.

The plan to obtain a storage dam on the Gila river for the irrigation of lands in the Florence-Casa Grande valley was started in 1895 by Arthur P. Davis, when it became apparent that some method would have to be devised whereby the lands of the Pima Indians could be supplied with water to offset the inroads into their water supply from the river made by diversions in the upper river for the lands of white settlers.

Surveys were made during the ensuing few years at a number of possible sites on the river with the result that the Box Canyon near San Carlos was finally selected as the proper place for the location of the dam. By 1915, a large number of surveys of the river, possible water supply and other data, including the depth of bedrock at San Carlos, had been made by the reclamation service and the reports filed with the department of the interior.

The Southern Pacific railroad obtained a right-of-way through the canyon, but when the railroad company failed to begin construction within three years, A. C. Sieboth and J. M. Jamison filed for a dam site on the river at the Box Canyon. A fight was made by the railroad company to get the right-of-way renewed. A board of engineers was appointed to investigate and they found a better site about 1,000 yards upstream from the original site and recommended that the site be preserved by all means.

Diversion Dam Built

Under their recommendations, a diversion dam was built 14 miles above Florence and the canal system in the project laid out. A committee was then appointed to work with federal authorities in drafting a contract for the project and on May 1, 1919, the contract for the project was approved by the Secretary of the Interior and the project declared feasible, which settled the question as to the construction of the diversion dam. The following winter, February, 1920, the construction work on the Ashurst-Hayden diversion dam was started.

Having obtained the diversion dam, the residents of the Florence-Casa Grande valley then started a movement in August, 1920, for the construction of the dam at Casa Carlos.

A bill was introduced in congress by Senator Cameron calling for an appropriation for the dam, and early in 1924 the bill was passed in the senate. It was later passed by the house, and on July

7, 1924, President Coolidge signed it.

The bill authorized the appropriation of $5,500,000 for the construction of the dam, of which $450,000 was to be made available at once and the rest was to be appropriated as needed by congress. It is estimated that about five years will be required to build the dam and to complete the system.

Ground-Water Studies Should Pave Way for Developments

(*Continued from Page 20*)

of recharge so that a permanent depletion will be effected depriving the complaining over-lying land owners of an adequate ground-water supply. On the other hand, there may be a surplus of ground-water existing which may be taken if the projected development would not substantially burden the first takers. Interference, to intervening degrees, frequently results in the rights of each owner being determined in court, or, after investigation of the facts involved, amicably adjusted.

Artesian wells act similarly except that, in place of cone depression forming and the interference taking the form of a lowered water level, areas of lessened pressure result and interference is marked by a lessening of artesian discharge.

Complex Issues Presented

When the water-table is lowered through pumping operations over a wide area formerly the source of springs the flow of which was appropriated for use, or traversed by streams whose water had been all appropriated, the result is frequently a cessation of the spring flow or a decrease in the stream flow through induced seepage, and it may be made grounds for an action at court by the appropriators. The principal questions of fact involved are: first, whether or not the source of the ground-water is the appropriated water; second, the lateral extent of the area affected; and third, to what extent is the appropriator deprived of needful water through the operations of the ground-water user.

These questions would involve a study of the available supply for all purposes, and the portion of the supply necessary to satisfy the needs of the appropriators. Such an inquiry would result in the determination of whether or not a surplus of water exists from the supply over the needs of the appropriator, and the amount of spring flow intercepted or stream seepage induced by the pumping, which are the principal modifications resulting. This data would point to the answer to the question when and how such a taking deprives the appropriator of his rightful water, and the sugges-

tion of remedies through which the resources could be conserved and developed without injury to prior rights.

The construction of infiltration galleries and subsurface dams are similar in effect to both the ponding of surface water and the pumping of ground-water, in that they are designed to cut off the underflow from passing to lower lands and offer a new outlet for ground-water, thus creating an elongated cone of depression.

Common Fundamentals

In practically all problems presented to the ground-water hydrologist, the occurrence of the ground-water and its nature, source, extent, and direction of movement under normal conditions, must first be determined. Then the modification of these conditions due to human agencies are studied in relation to extent of effect, amount of effect, present result, and projected result of such modification. He must have a knowledge of geology and hydrology so that he will be able to make a collection of physical data in the form of geologic and topographic surveys together with well logs, and be able to prepare maps and profiles depicting the *geologic construction of the region* considered, and the relation of the topographic features to geologic and other conditions. He must make a collection of rainfall, run-off, and evaporation data, and translate it into charts or diagrams for ready understanding and analysis; and to present, in a manner readily understood, the relation of the *hydrographic data* to the occurrence of ground-water in the area.

The degree of refinement of method and detail of investigation justified by the problem depends largely upon the values involved and the purpose of the investigation. Investigations of the facts involved in disputed ground-water problems, the results of which may materially affect valuable water rights or set the money value of damages, justify exhaustive study, and one should not consent to appear in court as an expert advisor (or an advocate, as is usually the case, unfortunately) unless he has been given opportunity thoroughly to investigate and to prepare the solution of his problem. All this takes a special training and experience.

In conclusion it is believed by the writer that the trend of present development, with the magnitude and diversity of problems it presents, justifies the time spent in specialization in the study of the basic principles involved in ground-water hydrology, either while the engineer or geologist of the West or Southwest is obtaining the broad fundamental and important collegiate training of his profession, or immediately thereafter.

MANAGEMENT

GETTING THE MOST OUT OF EVERY FURROW

By W. M. MERTZ*

GIVEN a definite stream of irrigation water every 30 days for example, what are the methods of orchard management which will conserve this to the greatest extent?

In the first place, irrigation water, to be of any value to the tree, must enter the soil. Since most of citrus feeding roots lie in the zone of earth from six inches from the surface to from 30 to 40 inches in depth, we are interested primarily in placing the largest possible percentage of the irrigation water between these two levels. The greater amount of surface soil we wet the greater loss from evaporation. If we soak the land to depths over four feet we have wasted not only water, but have washed out of our feeding zone valuable plant food. Too many furrows are wasteful of water since too much surface is wet only to be lost by evaporation. Too few furrows often mean an undue amount of waste water, and an inadequate portion of the root zone is wet, and very often too deep soaking results directly below the furrows, especially at the upper end.

It is thus very important to know the movement of one's irrigation water so that one can gauge his practices accordingly.

Extra Pipe-Line Saves Water

Most sandy or loamy soils with an average grade cannot be satisfactorily irrigated for a full ten acres length or 600 feet without wasting water at the upper end of the run by too deep soaking. Thus many of us would conserve much water for our trees by using an intermediate pipeline. Again by having this shortened distance to run the water, a lesser amount of time is necessary for the water to reach the lower end and this part of the orchard which usually receives too little water will improve from the added supply it receives.

Again with this middle pipeline it is not usually necessary to flush the furrows through by using large streams of water in them for a short time, repeating this procedure until all have been rushed through and then setting the water on the entire tract, a practice all too common on the lighter soils where the runs are long.

For a time this flushing system works reasonably satisfactorily, but usually results ultimately in the piling up of fine silt at the lower end of the grove which takes water more slowly than the rest of the orchard, drys out more slowly and is commonly puddled by working it too wet until a condition finally results which causes the relative amount of water absorbed at the lower end of the furrows to be very much less than throughout the major part of its length. This condition is so pronounced in many orchards today that even where middle pipelines have been put in and cross checking the lower ends adopted, the lower trees in the rows show marked signs of drought during most of the summer.

Shorter runs and running the water slower, or if possible, at a lessened grade, will avoid this condition and save much water for, under adverse condition such as I have just described, much water is lost by too deep soaking at the upper end if the lower end is to be wet up at all and usually an undue amount of waste water results in an attempt to hold a stream of water on this tightly compacted lower end of the orchard. With middle pipelines I have frequently found it necessary to run the lower half of the grove a longer interval than the upper; in extreme cases as much as eight hours on the upper end and 16 on the lower to get uniform penetration.

The Cultivation Question

Next comes the question of cultivation as it relates to irrigation efficiency. We have all been prone to consider that the work of irrigating our grove would almost entirely be lost if we did not establish a finely pulverized dust mulch just as quickly as we could get onto the land. The work of Prof. Veihmeyer and his associates occupied your attention in the morning session (Prof. Veihmeyer's paper appeared in the May issue of MODERN IRRIGATION) and I hope we have all disabused our minds of all our old ideas concerning the value of cultivation as a means of preventing losses of irrigation water by evaporation.

Nevertheless, cultivation is absolutely necessary as a means of preventing weed growth during the active growing season of our trees as well as the making possible the plowing of adequate furrows for subsequent irrigations. Some soils crack so upon drying that water penetration may be satisfactory when water is repeatedly run in the same furrow and on such types it is often a waste of time and money to cultivate after each irrigation unless weed growth is so rapid and the inter-

Summing It Up

Efficiency in irrigation depends primarily on the grower's intimate knowledge of his own soil. With this knowledge at hand he will find he is best able to use water efficiently if he can control the times when he takes the water and possibly the amount which he takes per run.

Lessened cultivation will markedly assist in bettering the penetration of water, especially at the lower ends of furrows.

Shortening the length of the furrows by middle pipelines will make for more even distribution and more efficient use of water.

The use of bulky organic manures and cover crops will not only aid the soil in taking water, but also increase its power of holding water against the pull of gravity.

Less flushing of the furrows by shortening them will reduce the packing and tightening of the soil near the lower ends of the furrows, thus tending to keep the orchard more uniform.

**This is the conclusion of Mr. Mertz' article in the May issue, in which he discussed the superiorities of the "Application System" to the schedule system for citrus irrigation. The article is reprinted from a paper delivered by the author to the Citrus Institute, and, while it was intended particularly for citrus growers, contains many valuable thoughts for other irrigators as well.*

vals between irrigations so long that undue weed competition is apt to result unless cultivation is resorted to after each run.

Certain it is that on some soils half the annual cultivation bill can be eliminated by cultivating thoroughly only after every other irrigation. In fact, on heavy clay soils having a tendency to crack, the furrows should be made several days in advance of the irrigation so that the bottom of the furrows may check and crack in order to get the most satisfactory penetration with the least surface soaking. On certain tight red clays which did not crack upon drying, a deep cultivation when the soil is rather dry seems to result in the best penetration of water, and on such types of soil it seems wise to do one deep working between each irrigation during the summer, since the furrow bottom tends to bake and usually takes water very slowly unless broken up.

Don't Work It Too Wet

The big thing with such a soil is not to work it too wet and also not to work it enough to reduce it to too fine a powder. This can be done by omitting all harrowing and waiting until the land will cultivate rather cloddy. A few workings of this sort and you will be surprised at the relative change in toughness of the clods which results from never powdering or working the land too wet.

On our sandy soils many of us do not have sufficient water to wet the centers between the trees both ways every run and the common practice of cultivating two or three ways when the water has been run only one is absolutely unnecessary and actually harmful in that puddling of the surface soil can just as surely be done by working and reworking dry soil as by working it too wet.

Where we have no trouble in getting ample penetration of our water cultivation should be limited to just as little as will permit of the keeping down of weeds and the remaking of new irrigation furrows. A soil worked only when rather dry and then only once will soon show improved receptions of water and less surface wet. Many a heavily cultivated grove will show a very wet surface after an irrigation with practically a dry subsoil when one lightly tilled will be soaked much deeper but show only the furrow banks wet.

Short Runs Profitable

Many of us have been accustomed to figure that 24 hours was as short a run of water as we could use and get satisfactory penetration, when, by actual measurement, it has been found that

KILLEFER

Methods of Irrigation

Accomplish These Beneficial Results:

Store water away in the soil DEEP=in narrow well-cracked furrows as deep as 26"=

Store it safe from wind, sun and runoff=

Leave the topsoil comparatively dry=

Permit wetting of uneven land=

Leave the ground easy to smooth off=

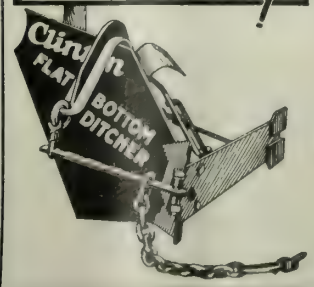
Get moisture quickly and cheaply into the root zone, no matter what the soil or crop.

We have special irrigation tools for the panbuster and cultivator. Write for special literature and name of nearest dealer.

THE KILLEFER MANUFACTURING COMPANY

Box 606, Huntington Park, Los Angeles, Calif.

Make Your Ditch a Natural Water Course



Here are— 5 Advantages:

you'll appreciate in this tool:

1. It builds a ditch which carries more water than a "V" ditch, depth and fall being equal.
2. The "off" horse walks on the flat ditch bottom instead of on the slope.
3. Silt fills this type of ditch more slowly and there is less overflow.
4. Erosion is minimized in the flat bottom ditch.
5. It can be cleaned out with greater ease for it keeps its shape.

PIPE

Both USED and NEW--At a SAVING to YOU!

WHENEVER and wherever you need pipe of any size or dimension, Pacific can serve you and save you money, too. For general farm and irrigation purposes, Pacific Reconditioned Casing is a real bargain. Absolutely guaranteed. Every length straight and clean with new threads and couplings, each protected from damage in shipping by special steel protectors.

Every length rattle-tested and steam pressure-tested as proof against weakness; then dipped in a special non-tasting hot asphaltum which resists alkali and corrosion. This adds years to its life. Nowhere else in the West, except in the Pacific plant, can used pipe be so thoroughly reconditioned and then sold at such low prices.

Ask either office for prices and free descriptive booklet

the upper ends receiving the full 24 hours showed a penetration twice as deep as needed. By shortening the length of the runs by the middle pipelines and putting in more furrows much less water would be lost by too deep penetrations and also a much larger area of the root zone would be wet and made capable of feeding the tree.

One is paying taxes on the entire acre of land and if he is only keeping the roots in feeding condition on half that land he is certainly not getting maximum results from his acreage. Some may not have the water to do this but most of us could increase the percentage of actual feeding area by studying our water penetration and so proportioning our supply of water that a more uniform distribution was made of the water. During dry years any appreciable amount of waste water is unpardonable, and if we make a real study of our soil and its capacity to take water we should be able to prevent waste water and ultimately so distribute it that 75 per cent of our trees would show improvement either from added water where they were getting too little or lessened water when they were getting too much.

Organic Matter Helps

Organic matter incorporated in our soils such as manure, alfalfa, bean straws and cover crops will aid materially in getting the soil in proper shape to take and retain irrigation water and no system of orchard management is on a right basis without due consideration of these materials in relation to its scheme of fertilization.

The total rest from cultivation which the growth of a cover crop gives to the soil is often worth more than the actual organic matter which it adds. In addition the washing of the soil and packing often resulting from heavy beating winter rains is wholly prevented by a good cover crop. These crops grow when normally the tree is requiring a minimum of moisture and nature is supplementing our irrigations by rains. The early spring incorporation of this bulky green mass of leaves and stems puts the soil in an ideal shape to absorb and hold such spring showers or rains as are common, and puts us in fine shape for the irrigation season ahead of us. Often these rains absorbed into this friable mass of soil will so function as a damp blanket over the deeper subsoil previously wet by the winter rains or irrigations that once the cover crop is plowed down no further work or irrigation may be necessary for a couple of months.

Electric Drilling Outfit Brings Big Economies

Savings in operating expense of more than 75 per cent over steam operation, together with a number of other advantages, resulted from a change-over from steam to electricity in drilling water wells in one instance in the Tulare Lake district of California. In this district the water question has always been a vital one. It was once necessary to build dykes to keep the water from flooding the land and it is necessary now to drill wells approximately 2,000 feet deep to find a source of supply.

Rotary rigs are used to drill the wells. Jake Smith, a local well drilling contractor, had been using steam as the power for his rigs but changed over to an electric oil well pumping outfit on one of the drilling rigs. With this outfit he now obtains speed variations from approximately 1200 r.p.m. down to 300 r.p.m. on the motor. The equipment, together with speed reduction gears, was mounted on two heavy timbers (12" by 12"), forming a sled which is easily moved with a tractor from one location to another.

Since adopting the electric outfit for drilling a large saving has been shown. With steam power it cost between $350 and $450 for fuel oil to put a well down 2,000 feet while the power bill for electric drilling has averaged approximately $90 per well.

With the steam outfit it took approximately two weeks to move and set up ready to drill, while, with the electric equipment, but three days are needed to move and set up ready to drill. Furthermore, the time of drilling has been reduced approximately 50 per cent with the electric rig. A further saving has resulted from the fact that one man less is needed on the crew of the electric rig.

Based on actual operations, Mr. Smith estimates that the electrical equipment has easily paid for itself out of the savings resulting from the drilling of three or four wells.

Report Imperial Crops

A crop report of the Imperial Valley, California, recently announced, shows that of a total of 605,000 acres on the American side of the international bounary, 369,633 acres represents the net area in crops. Of this total 289,132 acres are in field crops, with alfalfa leading (155,080 acres) and cotton second. Garden crops comprise 77,335 acres, 34,593 of which are in lettuce, and 30,774 in cantaloupes. Ten thousand acres are in permanent crops, such as orchards and vineyards.

You *Name the* Load
We *Make the* Pipe!

SINCE concrete pipe (as made by Bent) came into its own, engineers question no longer its striking advantages for a great variety of uses. *But*—a concrete pipe installation is either a mediocre or an eminently superior job of work, depending upon who fulfilled the contract.

Many trade names have become hall-marks of tradition, that serve as an unerring guide to discriminating buyers. Today the name "BENT" on a joint of Concrete Pipe marks it as a strictly finely made product. The same care and skill is exercised in its manufacture, and in the laying of the line, as though every future contract depended on *that* job meeting the fullest requirements of specifications—*and more.*

Let us give you a "concrete" demonstration of what we mean by "Bent" Service.

Of Interest Expressly to Water Works Engineers, Superintendents and General Managers

Irrigation Supplies May Be Used for Domestic Purposes—But Be Sure They are Pure!

By R. F. GOUDEY

Resident Engineer, Los Angeles Office, California State Board of Health.

THE IDEA of chlorinating irrigation supplies probably is new to most irrigation men; that is, if the present very poor sanitary showing of the majority of systems can be taken as a criterion. Not only have unforeseen conditions developed in the older supplies, completely changing the original character of the supply, but there is too great a tendency on the part of irrigation engineers even now to neglect sanitary features.

Volume is probably the first requisite of irrigation water. Moreover, wherever fresh water occurs or is made available, it should be used for irrigation at least so far as the southwest is concerned. The way it developed should include consideration of the public health aspect. Already neglect of this phase is crystalizing two very serious problems, which, if not corrected in time, will spread havoc not soon to be overcome. Chlorination in this connection will probably prove to be the greatest boon to irrigation.

Blame Western Crops

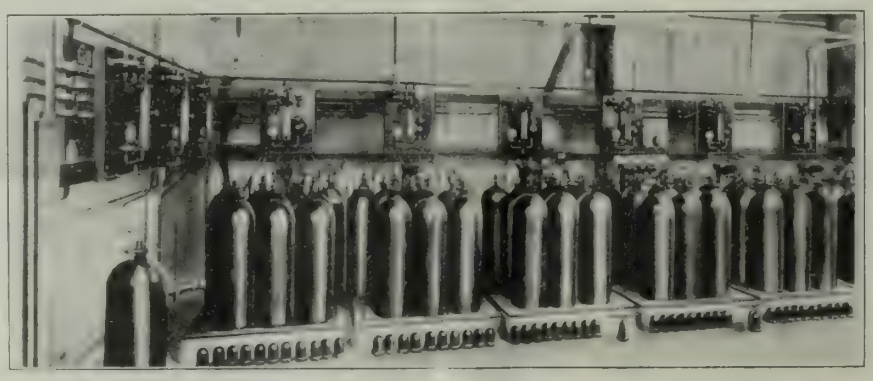
In the first place one of the most serious problems confronting irrigationists is the always threatening tendency of eastern health officers to blame eastern typhoid epidemics on western crops known to be irrigated with waters heavily polluted with sewage. Already large and valuable shipments have actually been quarantined. Many of the irrigation supplies are polluted with B. Coli or sewage characteristic microbes to the extent of one hundred per each cubic centimeter and are steadily getting worse. Either this contamination must be reduced at its source, the water treated, or restrictions made as to types of crops which can be grown with each individual water. Otherwise just enough quarantines will be made to jeopardize the entire industry. Chlorination is one of the first lines of defense from such attacks.

The second problem confronting irrigationists is the increasing number of typhoid fever cases in districts using polluted irrigation waters. Already several small epidemics have occurred. With ever-increasing pollution of most supplies this question becomes one of paramount importance.

Typhoid fever in the present enlightened age is inexcusable. The use of polluted irrigation water for drinking purposes or even waters subject to chance pollution is none other than criminal. While it is impractical to evaluate loss of time, suffering and disagreeable experiences of those suffering from the disease or to ever restore family ties of one dying from typhoid fever, courts have recognized, in a cold-blooded sort of way, that $1500 is little enough for medical care and loss of time to each patient and $10,000 to $25,000 as an average estimate for the value of a single death. Hence if but five cases, with one death each year, in any district, can be averted by proper treatment of water, it would warrant the expenditure of a minimum of $17,500 a year. Protection of irrigation supplies is not an academic or theoretical question. It cuts deep to the very heart of the industry and raises questions of economic necessities.

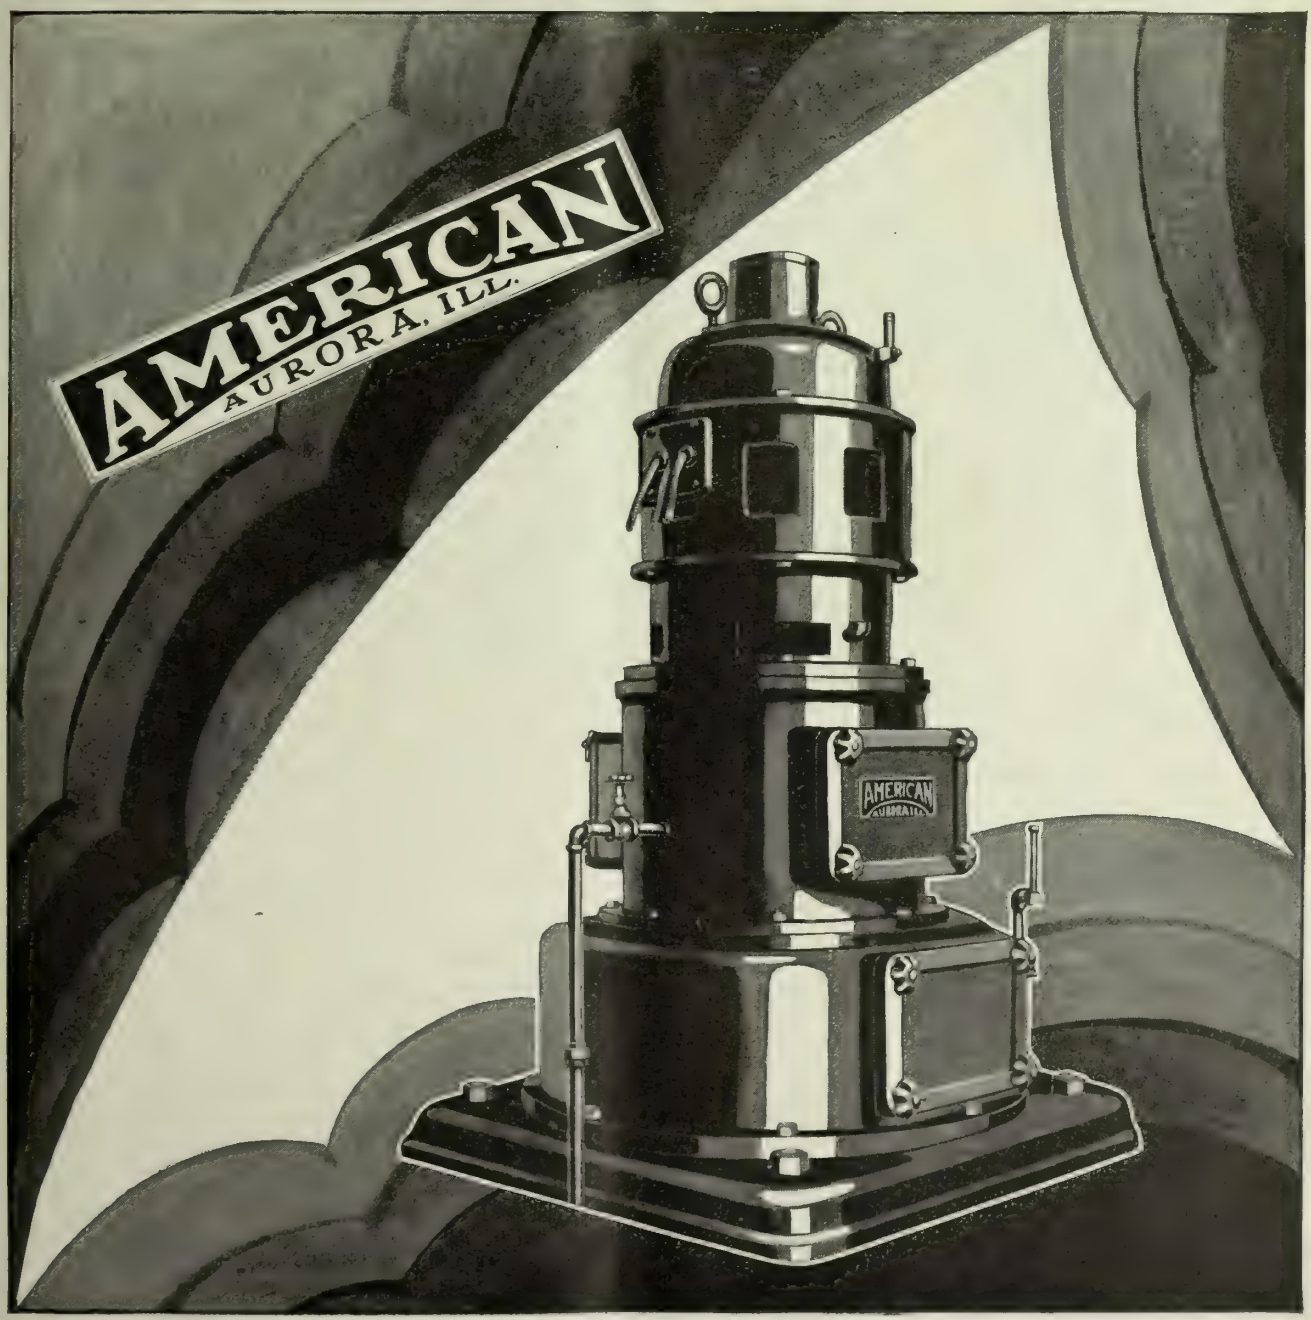
Should We Drink Irrigation Water

But the question is asked "Why let people use irrigation water for domestic purposes?" Some companies in order to protect themselves legally notify their customers not to drink the irrigation water, but with the full knowledge that their consumers have no other source at all for domestic purposes. Occasionally, a district is formed having a dual system to each farm, but this precaution is by no means common. Of late, many new supplies have been developed using the irrigaion supply for domestic purposes with the companies charging separately for domestic and irrigation water but with no thought of treating the supply or foreseeing any immediate unfavorable change possible to it. However much education is given to prevent using the irrigation supply for domestic purposes the fact remains that it is used and under a great variety of different circumstances.



Chlorination apparatus which treats every drop of water supplied to Greater New York. This is the Dunwoodie installation, which has been in continuous operation since 1916.

In a brief discussion such as this is, it is impossible of course to begin to touch upon all



THE high hydraulic efficiency of "American" pumps, their compact design and their sturdy construction all make for years of low cost performance. They are largely preferred by consulting engineers—whose discriminating opinion can be safely accepted as a criterion.

Better still!

—A responsibility that covers your water supply

Many users of Fairbanks-Morse pumps have installed these pumps because they wanted F-M responsibility behind the pumps they used.

Many users of Fairbanks-Morse motors installed these motors in order to have F-M responsibility behind their motors.

Yet, others—usually with the longest experience—have specified Fairbanks-Morse Motor-and-Pump Units, because—

They wanted a single responsibility behind their WATER SUPPLY.

When both driving and driven units of the pumping equipment are made by one manufacturer there is no question about who will stand behind the overall efficiency. And it has been the experience of a large number of pumping equipment users that Fairbanks-Morse guarantees have always been satisfactorily met!

of the different dangerous sources of pollution which are found in actual practice. The most common faults deal, first, with the water at its source, and second, with the types of construction used to convey it to consumers. Gross pollution results when domestic sewage is allowed to discharge in irrigation canals or streams. This practice is by no means rare, and in fact is far more prevalent than many irrigationists realize. The next most serious source of pollution is from summer mountain resorts and mountain cabin sites. Theoretically this danger should not exist. Inspections always reveal a large number of overflowing cesspools or cesspools located too close to streams. It can be safely said that none of the mountain resorts or cabins have permanent facilities for safe sewage disposal.

Then, too, the National Forest Reserve has invited the public to the nation's playgrounds, but with no provisions whatever for safe sewage disposal. With the advent of the automobile, more leisure time for the average person and the ever increasing number of mountain roads, literally place many thousands of campers on the headwaters of irrigation streams yearly. Sanitary facilities for these people, where not lacking entirely, are unreliable and inadequate.

A Recent Example

One of the most recent outrages has been the wholesale and deliberate stocking of reservoirs with fish and the migration of low type fishermen as well as duck hunters who remain in boats or along the shore line for many hours at a time, if not for an entire day, and with no sanitary conveniences at hand. Contamination of the supply under such circumstances is inevitable. A recent circularization of domestic water works in the United States shows that no fishing or hunting is ever allowed on supplies having no purification works. The novice at once calls attention to the enormous dilution in most reservoirs, declaring that to be sufficient safeguard. True it is that storage is a very important factor of safety, but it fails completely at low water stage, when the reservoir is rapidly filling and when winds are toward the outlet tower.

Another common fault in most supplies is failure to protect gravity pipe lines or flumes from storm water runoff. Very serious pollution may enter from such sources. Care should also be given to the design of gravity lines, flumes or canals to prevent storm runoff entering the supply where it would allow farmyard drainage or human excreta to be washed in. Failure to fence canals sometimes allows large animals to gain access. The use of canals for swimming should also be discouraged.

Chlorination is simply a means of reducing bacteria in a water supply without affecting any appreciable physical or chemical change. It is really the least that can be done and should not be confused with filtration, which is a more complete form of treatment to be used with difficult and highly polluted waters. The process is merely one by which liquid gas, contained in iron cylinders, is converted to a gas by the release of pressure, and after metering, added to the water supply. The machine for this purpose consists primarily of regulating valves, a compensating valve to give a constant flow of chlorine regardless of the varying tank pressure, an orifice type of meter for control and a diffuser to apply the chlorine gas to water. This equipment is compact and takes up very little floor space. There are different types of machines for varying installation conditions. Care, however, should be taken in properly locating the plant of a system so that all of the water is treated at the proper point.

The amount of chlorine required for disinfection varies from two to four pounds per million gallons. The more vegetable growth or mud the water contains the higher will be the required amount of chlorine to secure disinfection. The dose usually has to be adjusted to seasonal variations also.

The cost of chlorination is almost negligible. A good type of machine varies from $750 to $1,500. Liquid chlorine costs about fifteen cents a pound. Assuming that a supply of 2,000 inches or 78 acre-feet is to be chlorinated for nine months of the year with an average dose of three pounds of chlorine per million gallons, the cost of the best equipment including severe depreciation, interest and chemical, will be less than $3,000 a year. This cost would cover the expenses of two cases of typhoid fever but would be far less then the cost of a typhoid fever death. It is thus seen that this method of treatment is relatively cheap, affords good insurance to consumers and is a safeguard worth consideration.

Pertinent Questions

The first questions which arise are: "Will chlorine have any effect on soil?" "Will chlorine kill biological life or plants?" "Will it cause the water to taste?" When chlorine is added to water the greater part of it is immediately absorbed by the organic matter. Some of it is left for disinfection action. No free chlorine will be found in the water fifteen to twenty minutes after treatment. Chemical analyses will

RECLAMATION

RAILROADS AND RECLAMATION WORK TOGETHER

By HARDY W. CAMPBELL

RAILROADS and reclamation go hand-in-hand—both are pathfinders and empire builders; one seldom succeeds without the other.

It is unnecessary to say that the railroad is interested in irrigation. The railroad hopes to see every mile of its line producing something—not alone because it is dependent upon the tonnage it hauls, but because, naturally, the human element prefers to be surrounded by lands that are fruitful and green, supporting a clean, well-fed and contented populace. Such a condition is best for everyone and is the backbone of a nation. There are always families seeking new homes, therefore, the better agricultural results and conditions that a given section can obtain, the greater will be the tendency for such people to seek homes in that locality.

Benefits Not Expressed in Figures

Owing to the absence of records of a trustworthy character, it is practically impossible to state in figures from a tonnage standpoint what particular irrigation projects have accomplished, but it is manifest to all who will give any study to the question that many blades of grass have been made to grow on arid lands where no form of production appeared before; hence figures alone, even where available, fail to tell the story. The point is that these developed projects have produced new wealth for the individuals and the nation, and have provided a great source of new supply. Without them, we would not have the abundance of fruit and vegetables that now have become a necessity, but we would be going on as after the Civil War, when the daily menu was largely meat, wheats, potatoes and eggs. Fruits and vegetables, now so strongly advocated by our modern medical fraternity, were then delicacies beyond the reach of the ordinary person; today they are necessities, and to a large extent produced on irrigated lands.

California, probably of all of the western states, has attained the highest state of development through irrigation projects, and some idea of the results can be obtained from such figures as are available.

It is estimated that the irrigated area of California consists of approximately six million acres; this includes all land for which irrigation facilities have been provided and not abandoned—that is, lands which are irrigated annually or as needed, when water is available. Of this area some 2,753,095 acres are included in the active Wright Act irrigation districts, the Wright Act being a law passed by the California Legislature under which state aid is obtained under certain conditions. The balance of the area, or approximately 3,250,000 acres, represents lands that are served by mutual companies, commercial canal companies and individual private enterprises.

There is no segregation of data available that will show distribution or amount of production through irrigation enterprises as compared with other cultivated lands. The production figures are reported by crop varieties and for the state as a whole. However, that some idea may be obtained as to what has resulted, we may say that the beginning of irrigation on a large scale occurred in 1900, progress being slow until 1910; but from that period up until 1920, the extension of irrigation projects was rapid, particularly during the latter part of the period.

What California Produces

In 1909 the estimate of farm production of irrigable crops, such as orchard and vineyard varieties, was 2,108,307 tons, with a farm value of $48,718,000.00. In 1924, the records show a production of 3,020,000 tons valued at $178,000,000.00.

About as concrete an illustration of the value of irrigation as it is possible to offer, from a tonnage standpoint, is the Imperial Valley in California—not because other irrigated districts have not progressed, but because, situated as it is in the extreme southeastern corner of California, with the Colorado River on the east and the Mexican state of Lower California on the south, it represents an isolated territory and dependent upon irrigation for the production of any crop.

The irrigation project of this valley was started in 1900. The first water was brought into the valley in 1901. Picture, if you will, prior to that time the valley lying below sea level and nothing but a bleak uninhabited desert known as the "Colorado Desert." Starting from nothing in 1900, the population of the county in 1910, was 13,591; in 1920, the population was 42,383; in 1924, the estimated population was 65,000. It has within its boundaries several very fine towns, among which are Brawley, El Centro, Calexico and Imperial. They are all modern and will vie with the oldest communities for their paved streets, electric lights, good roads, schools, churches, hotels and all other good things that go to make up a healthful and thriving community. Intensive cultivation has followed and, while I will not burden you with figures, I am constrained to say that with an annual irrigation district tax of $5.00 per $100,000.00 valuation, the territory has grown, and where in 1910 there were but 78,252 acres under cultivation, there were 557,000 acres under cultivation in 1924. Where the production in 1910 was almost entirely alfalfa, barley and milo, with some cotton and livestock, the production in 1924 not only shows a healthy growth in the production of the articles mentioned, but includes grapefruit, asparagus, lettuce, grapes and almost every variety of fruits and vegetables, in addition to its livestock and grain development.

An Agricultural Prodigy

The early records of carload shipments are not available but in 1924 there were loaded and shipped from the valley 33,207 cars, principally cantaloupes, lettuce, watermelons and other commodities in proportion. According to the census of 1910, there was 9,650 head of dairy cattle in the county, and,

Clearance

Mobility

LOOK under a Northwest, measure the distance from the bottom of the crawler base casting to the ground and compare it with any other machine. Note the absence of axles, gear housings, low hanging gears, and chains.

Here is clearance that allows the easy straddling of objects in the path — there is nothing to strike on high centers, break and cause delay, nothing to drag on the high spots when the treads sink into soft earth and the machine needs all its power—just another feature demonstrating that the Northwest was built with careful thought to the service it must give. Another reason for its being the most mobile dragline on the market.

according to the U. S. Department of Agriculture, there was 45,165 head in the county in 1923. It has become a wonderful feeding ground for beef cattle—more than 35,000 head of cattle were fed in the year 1923. The extent of this can be appreciated when I point out that the alfalfa production in 1910 was limited to 32,703 acres. In 1924, the acreage devoted to alfalfa was 151,000 acres; the average annual irrigation cost per acre for production of alfalfa amounts to $4.70. It is unnecessary for me to say what this means to the grower, but the growth of alfalfa and the feeding of stock has grown to be a most important industry and is carried along as a by-product, so to speak, of many of the land owners in connection with their production of fruits and vegetables and the dairy industry. In 1910 the assessed property value was $12,000,000.00; in 1924, it was slightly in excess of $51,000,000.00.

All sections of the country, of course, are not adapted to the production of citrus and tropical fruits; however, California, because of its pecularities, is going more and more to the growth of fruits and vegetables and this augurs well for Oregon and other western states, because in time it will mean a large demand upon these states from California centers of population. Even today California is a large importer of the hardier kinds of vegetables, such as potatoes and onions, as well as dairy products—butter, eggs and cheese, to say nothing of live stock, etc.

Cotton Is King

(*Continued from Page 12*)

ceded that the cotton industry apparently has passed the experimental stage in this Valley.

I have repeatedly heard the statement that it would be impossible for the cotton grower of the San Joaquin Valley to compete with the cotton grower of the southern States, but this is not true. Reduced fertility of soils planted for generation after generation to one crop, and the ravages of the boll weevil, have so reduced the yield per acre in the southern states that the cotton grower of the San Joaquin Valley is now in a position to compete on a cost basis with the southern cotton planter. The average yield per acre in the southern States is slightly less than one-third of a bale, while the yield per acre in the San Joaquin Valley has very nearly reached a bale per acre. This difference in yield makes cotton grown in the San Joaquin Valley cheaper per pound of lint produced than is the case in the South.

For Detailed Listings, Branch Offices, Etc., See the Buyers' Guide to Leading Supply Sources—Pages 55-56

Five years ago it was almost impossible to sell a bale of California cotton, even upon submitted samples, on account of the great variation of length and quality of staple, but today cotton buyers are scrambling for the San Joaquin Valley crop on account of the uniformity of quality and length of staple. The Valley, so far, has raised premium cotton, cotton that has commanded a premium of from one to seven cents in the open market.

This fact is partly the result of God-given climatic and soil conditions, and partly of the fact that our cotton has been raised under irrigation methods of growing with sufficient moisture at the proper time and no excess of rainfall that would tend to discolor and delay harvest. But although these are very important factors, they are not the most important. Success has been due, in great measure, to the fact that a few far-sighted men in this industry have fought for the idea of planting one variety only and have devoted considerable time to the production of pure seed.

Regardless of climatic or soil conditions, it would be absolutely impossible to raise premium cotton with mongrel seed. The Valley is also fortunate in the fact that, due to the interest of these same men, state legislation was secured, making of certain areas in the state of California, pure seed districts. But this legislation has not solved the problem of maintaining present production standards. This legislation has only made possible the maintenance of present high standards and it is still necessary to exercise every care to prevent contamination and ultimate deterioration of San Joaquin Valley cotton.

It is rather interesting to know that at the present time very little San Joaquin Valley cotton is actually consumed in the few mills on the Pacific Coast, as there are no mills on the Pacific Coast manufacturing high-grade fabrics for which this cotton is particularly adapted. As a result, California cotton is shipped to the eastern seaboard or to England, where it is manufactured into high-grade fabrics, which in turn are shipped to the Pacific Coast and the ultimate consumer in the West, literally speaking, pays the freight both ways.

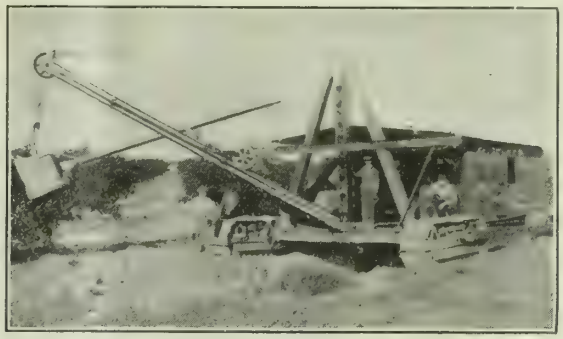
Horse Mesa Concrete Poured

Pouring of concrete was begun late in May on the foundation of the Horse Mesa power dam of the Salt River Valley Water Users' Association, in Arizona, after two years of preparatory work. The dam is to be of monolithic type, 312 feet high from bed-rock. The cost of the dam together with electrical equipment, will be $4,800,000.

For Cleanout -- Maintenance -- New Ditches

There's a Bay City for Every Job

BAY CITY Land Dredges span the ditch, can dig any desired slope, and dump waste on both banks. BAY CITIES leave clean, wide berms, and can work up or down streams. One trip over the ditch is enough. The Shovel Type Dipper handles hard material in which other types of buckets cannot make a good showing.



At left—One yard BAY CITY Dredge digging and cleaning ditches in Florida Citrus Groves.

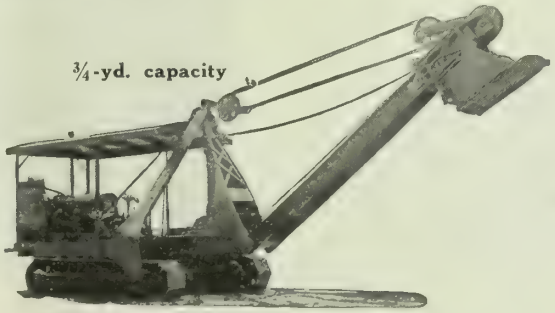
BAY CITY Land Dipper Dredges are built to fit the job. Walking, Crawler, Track or Floating mounting. Easily dismantled, transported and assembled. Capacities ½ to 1½ cubic yards. Oil engine or electric operation.

FOR SMALLER DITCHES — OR PIPE LINE TRENCHES

The BAY CITY 16-B convertible Excavator will handle a wide range of work. Operates Dragline, Trench Shovel, Clamshell or Skimmer. All steel. Shipped assembled. Digs any width or depth up to 20 feet.

STEEL CONSTRUCTION

¾-yd. capacity



FULL CRAWLER MOUNTING

or—Model 4 Excavator

BAY CITY Model 4 is a small low-priced convertible, one-man operated Excavator. Fills the gap between hand labor and high priced equipment. Capacity 20 to 40 cubic yards per hour. Gasoline or electric power. A Real Digger economically designed for the small job. Also operates shovel, and clamshell.

WHO'S *WHO* AND WHO'S *WHERE*

IN THE WORLD OF HYDRAULICS

Personal Notes and Impersonal Observations About Men You Know

A. R. Olsen resigned as a member of the Board of Directors of the Harney Valley (Oregon) Irrigation District in May and was succeeded by Ivan Oakes, appointed by vote of the remaining members of the board.

Arthur E. Cowell, of Merced, California, has been reappointed to serve as city engineer for the city of Livingston. The appointment was said to have unusual significance, as it carries with it the responsibility of preparing plans and specifications for a new sewer and water system for the town.

Prof. Frank Adams, of the Division of Irrigation Investigations and Practice, University of California, has just returned from a hurried trip through central and southern California, during which he collected material for a new edition of his state bulletin on the irrigation district movement in California.

W. W. Houser, of La Feria, Texas, well known among the water users of that section, has been named a director and temporary president of the Lower Rio Grande Valley Water Users' Association, succeeding E. C. Snow, who resigned the presidency and directorship of the organization on account of ill-health.

L. R. Hoagland has been appointed as temporary receiver for the Attalia (Washington) Irrigation District No. 1. His first step, in accordance with the instructions of the court, will be to collect $800 for cleaning out the district's main ditch so that water may be delivered to project lands. Members of the Walla Walla Chamber of Commerce will provide the funds.

J. O. McElligatt, formerly of the San Francisco office of the Commercial Acetylene Supply Co., Inc., is moving to the Los Angeles headquarters of his organization to take charge of the sales department. E. S. Bishop, who has been taking care of the Los Angeles territory, handling both manufacturing and sales, will devote his entire time to the plant as engineer and superintendent in charge of manufacturing.

JAMES M. KYLE

James M. Kyle, former president of the Oregon Irrigation Congress, and an ardent advocate of the Columbia River Basin project, in the interest of which he has spent the past winter in Washington, D. C., has returned to Oregon, and in May was the honored guest at various centers of irrigation and reclamation activity. At Vale, Oregon, he was honored by a dinner, and at Baker was tendered a complimentary luncheon. He brought the most optimistic reports from Washington as to the probable future of the Oregon projects, including the Vale, Owyhee and Baker projects.

Fred A. Noetzli, Los Angeles consulting engineer, was in San Diego during May conferring with Fred Rhodes, city manager, on plans for the selection of a type of dam to be used by the city in the improvement of its water system. Mr. Noetzli was one of the consultants who recently recommended the multiple-dome type of dam for the Coolidge dam on the Gila River, and there is a possibility that this kind of structure may be adopted by San Diego for its future construction.

R. H. Ehlers was elected president of the board of directors of the Palo Verde Irrigation District, succeeding Aikman Armstrong, resigned, and A. T. Galloway was named vice-president to take Mr. Ehlers position, at the May meeting of the board.

Judge Marvin W. Conkling, of Imperial County, California, has announced his candidacy for re-election as judge of the Superior Court. He was formerly attorney for the Imperial Irrigation District, and in the disputes which have attended the affairs of that district has usually had a prominent part.

R. H. Thompson, well-known Seattle engineer, has been selected to make a comprehensive survey of the water needs of Bellingham, Washington, and to prepare plans for a water system for the city. He was selected for the commission by the members of Bellingham's wateer board after they had interviewed a large number of leading engineers of the northwest.

Pomona, California, after weeks of reports and investigations on the value of the water system of the Consolidated Water Company, has named, through Mayor S. H. Park, a committee of citizens to conduct negotiations with the company for the purchase of the system by the municipality. The committee includes: J. F. Lobingier, L. L. Lostutter, A. L. Hickson and C. S. Vanderdeck.

Paul Bailey, deputy state engineer of California, in May conducted an inspection tour of the Santa Ana River watershed, in Southern California, in company with the engineering advisory board representing the three interested counties. J. B. Lippincott, A. L. Sonderegger and George S. Hinckley, representing Orange, Riverside and San Bernardino Counties, comprise this board. Mr. Bailey reviewed, in the field, the findings of a state survey party that has been working on the tributaries of the Santa Ana River for several months.

Rio Grande Growth Brings New District Organization

The federal Department of Agriculture has announced that owing to the great increase during recent years in the agricultural development of the lower Rio Grande Valley, Texas, the Weather Bureau has decided to establish, effective June 1, 1926, a new river district for the Rio Grande below El Paso, with headquarters at Brownsville. Daily reports will be received from river stations between Eagle Pass and San Benito, Tex., and a daily river bulletin will be issued containing river and rainfall data, river and weather forecasts, and also flood warnings whenever necessary.

This service was urgently requested some time ago by the business interests of the lower Rio Grande Valley, but it was not until the present time that economies in other fields enabled the Weather Bureau to provide the additional service. It is expected that the new service will be of great value to the agricultural interests at all seasons of the year.

The new district formerly formed a portion of the district of San Antonio, and the Weather Bureau station at the latter place will still continue to exercise jurisdiction over the Colorado, San Antonio, Guadalupe, and Naches Rivers.

Concrete Pipe Tests July 10

Announcement is made, as MODERN IRRIGATION goes to press, of an event which will prove of interest to engineers, contractors, public officials and others dealing with concrete pipe, and concerned with its properties. Public hydro-static and crushing tests are to be conducted under the auspices of the California Associated Concrete Pipe Manufacturers at ten o'clock Saturday morning, July 10, at the Merritt Company pipe yards, 1700 S. First Street, San Jose, California. The tests will yield data on the value of concrete pipe for irrigation, sewers, storm drains and culverts.

Survey for Big Kern Project

Engineers of the Kern County Canal & Water Company are making extensive surveys which may lead to the construction of a dam below the junction of the north and south forks of the Kern River, it has been announced by the company. The project, as tentatively suggested, would include almost 2000 miles of irrigation canals, and an irrigated acreage of 150,000 miles, according to reports.

DIGGING—CLEANING CANALS

AT LOW COST

THE NEW RUTH WITH ITS CONTINUOUS FLOW OF DIRT will dig or clean canals and trenches at a minimum cost per cubic yard or lineal foot heretofore considered impossible. The Ruth cuts continuous, even banks and smooth bottoms. Working successfully in marshy or dry ground, or canals full of water. The Ruth positively cleans the canal of all muck, sand, small willows, tules and water grasses.

Send for Bulletin No. 8—it illustrates the New Ruth Dredger; type and size of canals it will dig or clean; gives specifications, operating costs and maximum capacities.

LEGAL *and* JUDICIAL

A DEPARTMENT CONDUCTED BY HANKINS & HANKINS

Palo Verde District Organization Approved

Method of combining districts and of issuing bonds passed upon in California case.

The Palo Verde Irrigation District was organized under a special statute of the Legislature of the State of California, (Stats. 1923 p. 1067) for the purpose of taking over the properties and functions of three separate and independent agencies theretofore operating in the Palo Verde Valley and thereby eliminating the inefficiencies and extra expenses occasioned by the independent functioning of such agencies. The agencies so combined consisted of the Palo Verde Joint Levee District, the Palo Verde Drainage District and the Palo Verde Mutual Water System.

The method of organization was approved by the Supreme Court of California in the case of Barber v. Galloway, 195 Cal. 1.

In the case of Palo Verde Irrigation District v. Seeley, 71 Cal. Dec. 428 (Apr. 22, 1926) the method of issuing refunding bonds of the new district to redeem the bonds of the three agencies combined in the irrigation district was approved.

These cases are of importance in pointing out a way of combining various irrigation districts, reclamation districts and drainage districts in California where such districts are closely connected and could be operated more economically and efficiently as one organization.

Wells May Not Encroach Upon Ditches

Court holds that a land owner cannot sink a well so near an irrigation ditch as to diminish the flow of water in such ditch.

In the case of Lemm v. Rutherford, 49 Cal. App. Dec. page 368, (Feb. 5, 1926), the District Court of Appeal of California, third appellate district, held:

"The owners of a water ditch used by them for irrigating purposes, and extending in its course over the land of an adjoining owner over which they have an easement, are entitled to restrain such adjoining owner from pumping from a well erected by him on his said land immediately adjacent to said ditch the percolating and seepage waters from said ditch, and under such circumstances cases having to do with percolating waters, in the true sense of the word, have no application."

In distinguishing the cases concerning true percolating waters and citing the case of Katz v. Walkinshaw, 141 Cal. 116, the court states:

"The Walkinshaw case further holds that the law relating to percolating waters is very much limited and is governed largely by another rule, which is to the effect that one must so use his own property as not to injure that of another."

The appellants also urged in this case as was done in the Walkinshaw case, that the common law concerning percolating waters was applicable. On this point the court remarks: "the rule of the common law is not to be applied where the reason for it utterly fails . ."

Kansas Court Rules on Flood Damages

Holds action for damages to crops caused by obstructing a waterway is barred in two years.

In the case of Buss v. Missouri Pac. R. Co., 244 Pac. 1059 (April 10, 1926) the Supreme Court of Kansas held that the question of whether a channel was a natural water course is a matter to be submitted to a jury upon proper instructions from the Court as to what constitutes a "natural channel."

The Court further held that the cause of action for damages to the land itself arose when the obstruction was built but that the damages to crops arose when such damages occurred irrespective of the time the obstruction was placed in the channel and the statute of limitations of two years did not commence to run against such an action until the flood and damages occurred.

Ownership of Springs Expounded in Colorado

Court cites authority in discriminating between rights to water from spring flow.

The Supreme Court of Colorado in the case of Haver v. Matonock, 244 Pacific 914 (March 22, 1922) citing 1 Wiel on Water rights (3d Ed. 357) holds that, when a spring furnishes a stream of water that rises to the surface, the right of appropriation attaches, but, where the admitted quantity is so insignificant that a surface stream is impossible, when spread over the width of ground involved, the use of the water belongs to the person upon whose land it first arises.

Where Riparian Rights Conflict with Navigation

Supreme Court holds that power of Congress in relation to navigation takes precedence within necessary limits.

In the case of United States vs. River Rogue Improvement Co. 70 L. ed. (Adv. Vol 7, p. 148), Feb. 1, 1926, arising in Michigan, the United States Supreme Court considered the conflict between riparian rights of land owners and the right of Congress to control navigation.

The Court states: "The riparian rights of one owning land on a navigable river are of no avail against the exercise of the absolute power of Congress over the improvement of navigable rivers, but must suffer the consequences of the improvement of navigation, if Congress determines that its continuance is detrimental to the public interest in the navigation of the river."

However, the court does not hold that riparian rights cannot exist on a navigable stream and the right of Congress to control the stream is limited to the purposes of navigation. On this point the court says:

"It is well settled that in the absence of a controlling local law otherwise limiting the rights of a riparian owner upon a navigable river, he has, in addition to the rights common to the public, a property right incident to his ownership of the bank, of access from the front of his land to the navigable part of the stream, and when not forbidden by public law may construct landings, wharves or piers for this purpose."

This case is of interest, although it does not directly involve water rights, as no question of appropriation of water is involved. The right of Congress to control the navigable rivers of California and of the Western States will arise in the near future when irrigation will commence to conflict with navigation.

Rules Warrants Are Negotiable

Judge Everett Smith in the Superior Court at Yakima, Washington, has ruled that the warrant of an irrigation district is a negotiable instrument, in the case of William P. Harper & Son, Seattle bond firm, against the Pacific Power & Light Company. The power company received warrants from Irrigation District No. 4, Franklin County, in return for services, and endorsed the warrants to the bond house. When the district became insolvent, the holders of the warrants sued the power company.

Irrigation Under Tropic Skies

(*Continued from Page 17*)

lulu with Southern California oil. Although their water is costly this plantation produces the largest sugar tonnage per acre of any plantation in the islands, due to a highly perfected agricultural research department within its organization which has done much to eliminate wastage in the use of water. It might be helpful to reflect here that projects with cheap water are usually very poor producers due to careless and unscientific application of irrigation water, the results of which are drowned crops and water-logged lands. *The cost of the lack of control of cheap water is great.* The price is in the form of a drainage bill or a bankrupt farm.

These division weirs are typical of the distinctive type of irrigation construction being developed by American engineers in the Hawaiian Islands. They are found on the Hawaiian Commercial & Maui Agricultural Plantation.

The Ewa Plantation was the first to install irrigation meters to improve the control of their water distribution and to ascertain the amount of water required on their various fields to produce maximum crops of cane. The results obtained in 1924 in bringing about a more equitable water distribution among their several hundred irrigators independent of the duty of water data procured was so gratifying that a further quantity of meters was installed in 1925. By the end of 1925 the value of the metering system on Ewa Plantation had become so well known throughout the Islands that over 15 other plantations had ordered and installed meters. The largest installation, consisting of 200 meters, is on the Island of Kauai on American Factors properties. Here the major aim is to determine the duty of the various fields. In conjunction with most of the field duty determinations, submerged orifice meter measurements are being carried out on the various laterals and main canals to ascertain transportation losses.

Wasteful Methods Hit

Wherever meters have been installed, careless and wasteful methods of irrigation have disappeared. A Japanese irrigator who had been on one of the plantations for fifteen years approached the water overseer at one of the meters one

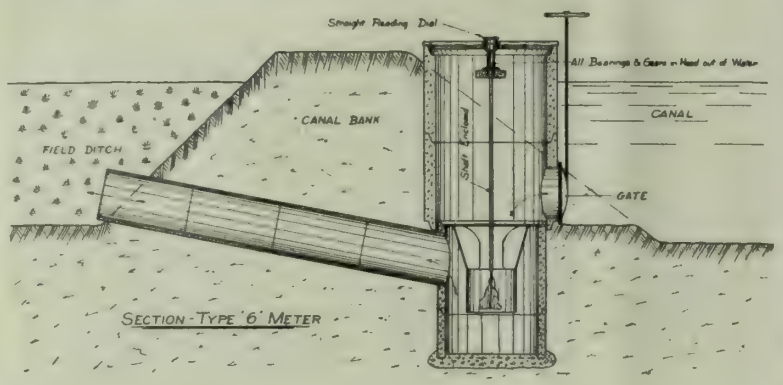
The RELIANCE METER



THE "Type 6" Reliance Irrigation Meter offers you standardized permanent construction at a very low first cost. Their sustained efficiency with a minimum of upkeep has been proven by 12 years usage. Cut shows installation of the 4 sec. ft. size in 24 and 30-inch concrete pipe. This is the standard type of setting adopted by many irrigation districts in Texas and elsewhere who are now equipping all their deliveries with this device. The "Type 6" meter is furnished in sizes ranging from ½ up to 16 sec. ft.

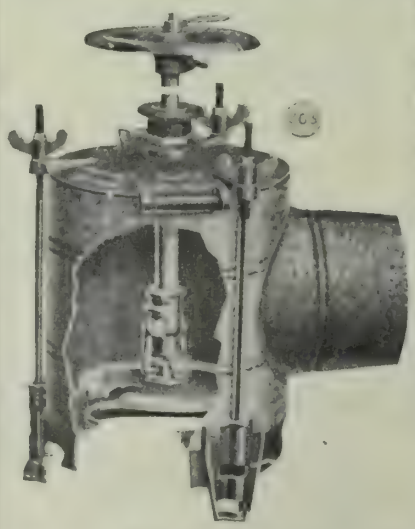
Alfalfa Irrigation

MADE EASIER WITH

The Martin Portable Hydrant



Martin engineers, specialists in utility irrigation appliances, never designed a more serviceable piece of equipment than the MARTIN PORTABLE HYDRANT. Its use with MARTIN Alfalfa Valves Type B and Type Q enables the irrigator to control the direction of flow easily. Four checks can be irrigated handily and the operator knows exactly the amount of water each check is getting.

The spout of the hydrant can be turned in any direction. Two hydrants are generally used on one pipe line. While one is set and operating, the other can be moved to the next valve and set up ready to operate. Surface pipe can be attached to hydrant before valve is opened. The valve is opened and closed by the wrench built into the hydrant. After the entire field is irrigated, the hydrants can be removed and placed in the tool house. As the Type B valve is flat on top, there are no obstructions in the field to catch the mower or rake.

We manufacture the original line of Irrigation Appliances Outlet Valves, and Cut-off Gates for the definite division of water over the field from Concrete Pipe Lines.

day and said: "Me no likee dis machine, because machine talk and head office know too very much about water." Human nature is similar the world over. When it recognizes that its conduct is going to get some publicity it becomes more conservative.

This same water overseer related another case where he had installed a measuring structure in a ditch where he had experienced a great deal of trouble in getting sufficient water down to irrigators at the lower end, due, he thought, to hoggish diversions by irrigators above. He installed the measuring structure but had no meter to place in it for several weeks. The meter box lid was padlocked, however, so the Japanese irrigators who soon discovered the orifice structure thought judgment was pursuing them and although there was actually no meter as yet in the structure the water shortage at the lower end of this lateral changed at once to a plentiful supply. This seemingly trivial situation had a vital bearing on economic crop production along this lateral. It is typical of conditions prevailing on many irrigation systems.

The irrigation of other crops is comparatively unimportant. Nevertheless, the rice fields planted mostly by the Orientals are a beautiful sight as you discover them lying here and there about the islands in little valleys, coves and low-lying areas where sufficient water is available to keep the fields flooded. The Hawaiian Islands would be only a beautiful spot on the earth were it not for the labor contribution of the Oriental and he would be a helpless factor without his rice.

The discussion of the pineapple industry does not come within the scope of this article but lest someone should wonder why the Islands' second greatest industry is left out of consideration it need only be mentioned that the pineapple is not irrigated. Nevertheless, it is worthy of mention because it fits in so well with the agricultural scheme of the Islands, making the higher non-irrigable lands useful for this industry.

Irrigation in Hawaii is the basis for practically all productivity and brings close to $80,000,000 or two-thirds of all its income annually to its population, supplying a means of livelihood to probably no less than 150,000 people and the sugar for millions of homes in America.

Urge $50,000 Bond Issue

Representatives of the Chamber of Commerce of Rialto, Calif., are urging a city election for a bond issue of $50,000 for the extension of water mains to outlying districts.

For Detailed Listings, Branch Offices, Etc., See the Buyers' Guide to Leading Supply Sources—Pages 55-56

You Can Use Irrigation Water for Domestic Purposes

(*Continued from Page 36*)

show that it has combined itself with other minerals in the form of chlorides. It does not have any effect whatever on the soil. The alkali content is increased less than one-half of one per cent. Since the chlorine is in the form of chlorides it will not have any disinfecting action on the soil. Water will not taste when chlorinated unless it contains certain types of microscopic growths which produce oils, which would taste any way. It would require a dose at least five times higher than recommended above, to cause taste in the water from chlorine alone. Aeration of irrigation supplies is highly desirable, but is not necessary in conjunction with chlorination.

Wherever chlorinators are installed the units should be in duplicate and a competent operator should be in charge to make simple daily tests to determine whether the treatment is effective, and a record of operation should be kept available for inspection.

Signal Hill to Ballot

Signal Hill (California) the oil city that grew out of Long Beach, and still depends on Long Beach water supplies, has moved to create an independent water system of its own. It is now planning for a bond election, to be held in July, at which a bond issue of $250,000 will be submitted to the voters.

Laguna Beach Starts Work

Work has been begun at Laguna Beach (California) on the construction of a $500,000 water system. A contract was recently let to Fisher & McCall of Santa Monica for laying 10,000 feet of 6-inch cast iron water main.

Newport Completes Reservoir

Newport Beach, California, has completed a new 3,000,000-gallon reinforced concrete reservoir, the first step in a $350,000 improvement program for the city's water system.

Lynwood Will Make Additions

City trustees of Lynwood, California, have approved plans for the addition of three-fourths of a mile of six-inch water mains to the municipal water system.

Increase Reservoir Height

Auburn, Washington, is adding a two-foot wall to the city's new rseervoir, thereby increasing its storage capacity by 1,000,000 gallons.

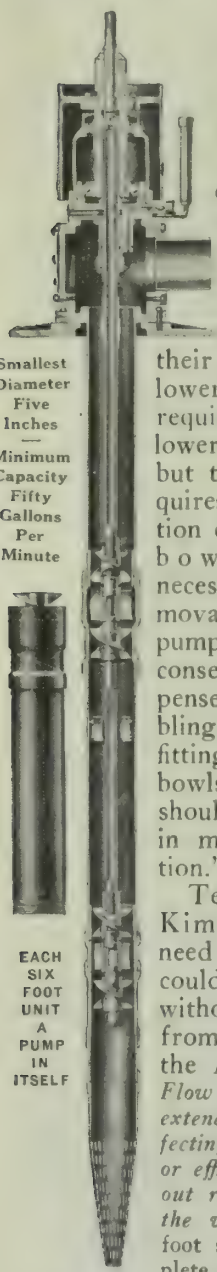
ITS NOT in the HEAD--- ITS IN THE PUMP!!!

U. S. Dept. of Agriculture says---



Smallest Diameter Five Inches — Minimum Capacity Fifty Gallons Per Minute

EACH SIX FOOT UNIT A PUMP IN ITSELF

Farmers' Bulletin No. 1404 on page 17, gives the following advice to purchasers of deep well pumps: "Manufacturers are likely to emphasize the ease with which their pump may be lowered to meet the requirements of a lowered water table, but this usually requires the installation of additional bowls or stages, necessitating the removal of the entire pump from the well, consequently the expense of reassembling the pump and fitting additional bowls or stages should be considered in making a selection."

Ten years ago Kimball saw the need of a pump that could be extended without removal from the well, and the *Kimball Direct Flow Turbine can be extended without affecting speed, capacity, or efficiency and without removing it from the well.* Every six-foot section is a complete pump.

Water Works Men Plan for October Convention

Directors of the California Section of the American Water Works Association met at Fresno in May to lay plans for the annual convention of the organization, which is to be held in San Diego during October. The directors at the same time received the Nicholas S. Hill cup, the trophy awarded last year to the California Section for its achievement in membership growth, the largest of any section of the association for the previous twelve-month.

Charles B. Jackson, president of the California section, received the trophy on behalf of his organization.

Courtesy San Joaquin Power.

A SOURCE OF JUSTIFIED PRIDE

Charles B. Jackson, president of the California Section of the American Water Works Association, expands his chest with pride as he receives the Nicholas S. Hill trophy awarded to the California section for the best membership record of any chapter in the organization.

Urges Probe of Water Problem

Representatives of ten communities of the San Francisco peninsula, acting through a committee recently appointed to initiate an investigation of the water problem of the entire district with its relation to possible solution through the Hetch Hetchy project, have made a report in which they urge a thoroughgoing survey designed to answer four principal questions.

The questions which the board deems necessary to investigate are:

1—When may we expect to obtain a water supply from Hetch Hetchy?

2—In the meantime, is a supply obtainable from the Spring Valley Water Company? And, if so, how?

3—Must the cities "go it alone" and seek individual sources of supply, and to what extent?

4—May all the peninsula cities join in an investigation that will answer the foregoing questions?

The committee's personnel includes Supervisors Shannon and Milo F. Kent of San Francisco, City Attorney John O'Toole, Professor C. D. Marx, president of the Board of Public Works of Palo Alto, and Oscar F. Weissgerber, city manager of San Mateo.

Salt River Valley President Sees Free Water in 1927

President F. A. Reid, making his annual report to the Salt River Valley Water Users Association in May, expressed confidence in the future of the organization, and, surveying the financial outlook, suggested that the water assessment for 1927 might be entirely eliminated by the sale of additional power. His report, in part, declared:

"The recent rains have guaranteed us a full water supply for this year. The apportionment has been increased to 3¼ acre feet delivered to each ranch. The careful use of water and the continuance of the operation of our pumps will guarantee us an excellent supply of water for next year also even if we should have a change back to drouth conditions next year. Such a contingency must be faced, and I would recall to you that in 1897, after five years of drouth, that spring rains produced as much water in the Salt River water shed as the recent storms and the following seven years were very dry ones. The pumps should be operated at full capacity until the reservoir fills except when the Verde river meets the irrigation demand. We have, therefore, fixed the budget at $3.96 per acre. This is $1.00 above the actual payment due the United States government for repayment of our debt and should be levied in order not to have the possibility of carrying over one year any shortage of revenue due to drouth conditions. If the reservoir fills before April 1, next year, we will be able to produce over $500,000 additional power during next year or the assessment can be cut to less than $2.00. I can assure you that if the reservoir does fill next year, in addition to reducing that assessment, the water assessment will be zero the following year."

After tracing the recent development of the association, Mr. Reid states: "Our irrigation system costs this year

with demand service will be but $2.00 per acre, less than any other large irrigation system with our long growing season, in the whole of America."

Touching upon the new project undertaken by the association, the Horse Mesa Dam, he reports:

The foundation of the Horse Mesa dam is now completely opened and ready for concrete. Concrete grouting of the rock has been in progress for the past two weeks and the concrete plant is ready for operation. A few more days will see concreting on a large scale. Our plant has a capacity of 1,000 cubic yards per day and with only 15,000 yards per month, which is our schedule will see the dam and power plant in operation in less than 10 months. There remains to be done to complete the Horse Mesa development, the following:

Excavation	$ 5,000.00
Grouting	20,000.00
River Control	10,000.00
Power House	100,000.00
Cement	420,000.00

	$1,650,000.00

Planes Patrol Forest Areas of Pacific Coast States

Airplane patrol of the forested regions of Pacific Coast states by the U. S. Forest Service started June 2. Planes are operating out of Mather Field, Sacramento, and Griffith Park, Glendale, and on June 16, forest airplane patrol will start in Oregon, Washington, western Montana and northern Idaho.

Airplane forest patrol was again made possible this year by a special appropriation of $50,000 by Congress. Planes will be supplied by the U. S. Pilots and mechanics have been selected from specially qualified officers and enlisted men of the Air Service reserve corps.

Airplanes will be used this year, primarily for the reconnaissance of burning fires, for patrol duty following lightning storms, and for the transportation of emergency equipment to the fire line. Patrol service will be rendered, on request, to state officials and other agencies cooperating in fire prevention in the Pacific Coast forest regions.

SURVEY *of* HYDRAULIC DEVELOPMENT

As Shown by Official Records of the Month -- Local, State, and Governmental

Permits Issued

Among the more important permits to appropriate water issued by the Department of Public Works, Division of Water Rights of California, during the month of May, 1926, were the following:

Permit No. 2479, Application No. 4837 (Los Angeles County) Isuued to John Snyder, Llano, Calif., May 11, 1926, for 0.004 cubic feet per second from Two Unnamed Springs in Section 24, T 4 N, R 8 W, S.B.M. for irrigation, stock and domestic purposes on 47 acres in said Section 24. Estimated cost $2000.00.

Permit No. 2480, Applicaion No. 4865 (Shasta County) Issued to Jay Boright, Buckeye, Calif., May 11, 1926, for 0.5 cubic foot per second and 5 acre feet per annum, from Grape Vine Springs in Section 10, T 32 N, R 5 W, for domestic and irrigation purposes on 26 acres in Section 11, T 32 N, R 5 W, M.D.B. & M. Estimated cost $1200.00.

Permit No. 2481, Application No. 4866 (San Luis Obispo County) Issued to Thomas W. Arnold and Charles T. Sorenson, Los Angeles, Calif., May 11, 1926, for 0.12 cubic foot per second and 18.5 acre feet per annum from Pozo Creek in Section 20, T 30 S, R 15 E, M.D.M., for irrigation purposes on 123 acres in Section 20 and 45 acres in Section 21, T 30 S, R 15 E, M.D. B. & M. Estimated cost $5000.00.

Permit No. 2485, Application No. 4922 (San Joaquin County) Issued to D. Muller, Stockton, Calif., May 13, 1926, for 2.15 cubic feet per second from San Joaquin River in Section 21, T 1 N, R 6 E, M.D.B. & M., for irrigation purposes on 172.1 acres in said Section 21. Estimated cost $2500.00.

Permit No. 2486, Application No. 4921 (San Joaquin County) Issued to M. Bronich, Tracy, Calif., May 13, 1926, for 2.99 cubic feet per second from Old River in Section 33, T 1 S, R 5 E, for irrigation purposes on 239.8 acres in Sections 26, 29, 32 and 33, T 1 S, R 5 E, M.D.B. & M. Estimated cost $2000.00.

Permit No. 2487, Application No. 4894 (San Joaquin County) Issued to Matie S. Vail, Stockton, Calif., May 13, 1926, for 8.1 cubic feet per second from Beaver Slough in Section 8, T 4 N, R 5 E, for agricultural purposes on 277.3 acres in Section 5; 373.0 acres in Section 8 and 0.6 acres in Section 17, all in T 4 N, R 5 E, M.D.B. & M. Estimated cost $32,500.00.

Permit No. 2488, Application No. 2217 (San Bernardino County) Issued to Water Conservation Association, Riverside, Calif., May 13, 1926, for 48,000 acre feet per annum from Santa Ana River in Section 9, T 1 S, R 2 W, S.B.B. & M., for irrigation and domestic purposes on 52,640 acres in T 1 S, R 3 and 4 W, T 2 S, R 4, 5 and 6 W, T 3 S, R 5, 6, 9 and 10 W, T 4 S, R 9 and 10 W, and T 5 S, R 9 and 10 W, S.B.B. & M. Estimated cost $1979.62.

Permit No. 2489, Application No. 4123 (Yolo County) Issued to S. Sweet Co., Visalia, Calif., May 13, 1926, for 23.0 cubic feet per second from Borrow Pit of Reclamation District No. 999, in Section 21, T 6 N, R 3 E, M.D.M., for irrigation purposes on 3698 acres in Sections 16, 17, 18, 19, 20, 29, 30 and 31, T 6 N, R 3 E, M.D.B. & M. Estimated cost $30,000.00.

Permit No. 2490, Application No. 4124 (Yolo County) Issued to S. Sweet Co., Visalia, Calif., May 13, 1926, for 7.12 cubic feet per second from Borrow Pit of Reclamation Distric No. 999 in Section 21, T 6 N, R 3 E, M.D.M., for irrigation purposes on 620 acres in Sections 20, 21 and 29, T 6 N, R 3 E, M.D.B. & M.

Permit No. 2491, Application No. 4698 (Santa Clara County) Issued to Montezuma Mountain Ranch School, Los Gatos, Calif., May 17, 1926, for 0.25 cubic foot per second from September 1st to June 1st and 0.10 cubic foot per second from June 1st to September 1st from Collins Creek in Section 7, T 9 S, R 1 W, M.D.B. & M. for domestic and irrigation purposes on 15 acres in Section 6, T 9 S, R 1 W, M.D.B. & M. Estimated cost $12,000.00.

Permit No. 2492, Application No. 2778 (Butte County) Issued to Oroville-Wyandotte Irrigation District, Oroville, Calif., May 17, 1926, for 50 cubic feet per second and 25,000 acre feet per annum from Lost Creek in (1) Section 20, T 20 N, R 8 E, M.D.B. & M., (2) Section 24, T 20 N, R 7 E, M.D.B. & M., for irrigation purposes on 31,463 acres within the boundaries of the District. Estimated cost $820,500.00.

Permit No. 2493, Application No. 1918 (Fresno County) Issued to San Joaquin Light & Power Company, Fresno, Calif., May 17, 1926, for 450 cubic feet per second from North Fork Kings River, North Fork Rancheria, Rancheria and Statum Creeks in Sections 6, 17 and 20, T 11 S, R 28 E, for power purposes in Section 6. 7102 T.H.P. to be developed. Estimated cost $3,500,000.00.

Permit No. 2494, Application No. 2024 (Fresno County) Issued to San Joaquin Light and Power Corporation, Fresno, Calif., May 17, 1926, for 125 cubic feet per second from Helms Creek in Section 7, T 10 S, R 28 E, for power purposes in Section 30. 23,011 T.H.P. to be developed. Estimated cost $2,500,000.00.

Permit No. 2495, Application No. 4703 (Fresno County) Issued to San Joaquin Light and Power Corporation, Fresno, Calif., May 17, 1926, for 220 cubic feet per second from North Fork of Kings River in Section 6, T 11 S, R 28 E, Section 1, T 11 S, R 27 E, Section 3, T 12 S, R 27 E, Sections 10 and 12, T 12 S, R 26 E, for power purposes in Wishon, Haas, Balch, Junction and Kings River Power houses. 141,750 T.H.P. to be developed. Estimated cost $32,300,000.00.

Permit No. 2496, Application No. 4704 (Fresno County) Issued to San Joaquin Light and Power Corporation, Fresno, Calif., May 17, 1926, for 330 cubic feet per second from Upper North Fork, Fleming Creek, Post Corral Creek and Helms Creek in Section 7, T 10 S, R 29 E, Sections 1 and 7, T 10 S, R 28 E, Section 26, T 9 S, R 28 E, for power purposes in Section 30, T 10 S, R 28 E. 60,750 T.H.P. to be developed. Estimated cost $10,000,000.00.

Permit No. 2498, Application No. 4743 (Sacramento County) Issued to Carmichael Irrigation District, Sacramento, Calif., May 21, 1926, for 10 cubic feet per second from American River in Section 22, T 9 N, R 6 E, for domestic purposes and irrigation of 3100 acres within said District. Estimated cost $120,000.

Permit No. 2500, Application No. 4849 (Mendocino County) Issued to E. L. Cunningham, Ukiah, Calif., May 21, 1926, for 1.65 cubic feet per second from East Fork of Russian River, in Section 22, T 16 N, R 12 W, for domestic and stock watering and irrigation of 132 acres in Section 22.

Permit No. 2501, Application No. 4856 (Butte County) Issued to P. N. Ashley, Biggs, Calif., May 22, 1926, for 8.91 cubic feet per second from Main Drainage Canal Drainage District No. 100 in Section 15, T 18 N, R 1 E, for irrigation of 356.5 acres of rice in Sections 15 and 16. Estimated cost $1150.00.

Permit No. 2505, Application No. 2774 (Amador County) Issued to Preston School of Industry, Waterman, Calif., May 26, 1926, for 8.3 cubic feet per second and 3750 acre feet per annum from Sutter Creek in Section 1, T 6 N, R 10 E, for domestic and irrigation of 663.93 acres near point of diversion. Estimated cost $75,000.00.

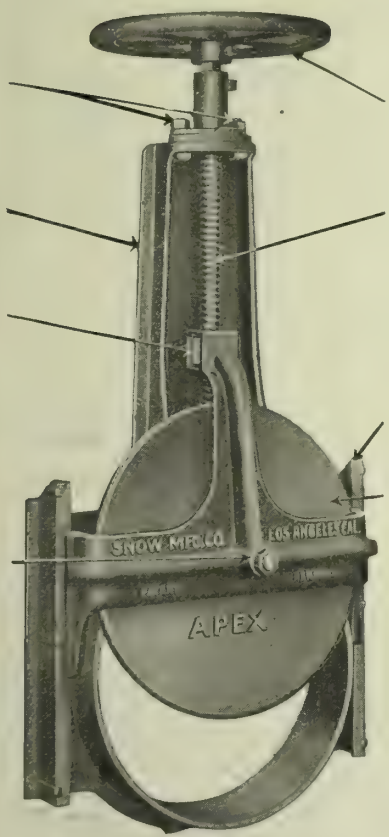
Permit No. 2506, Application No. 2775 (Amador County) Issued to Preston School of Industry, Waterman, Calif., May 26, 1926, for 10 cubic feet per second and 3750 acre feet per annum from Sutter Creek in Section 1, T 6 N, R 10 E, for power purposes in Section 24, T 6 N, R 9 E. 309 T.H. P. to be developed.

Permit No. 2507, Application No. 4388 (Sacramento County) Issued to Wm. J. Sheldon, Slough House, Calif., May 26, 1926, for 2.5 cubic feet per second from Cosumnes River in Section 3, T 7 N, R 7 E, for domestic and irrigation of 200 acres near point of diversion. Estimated cost $4300.00.

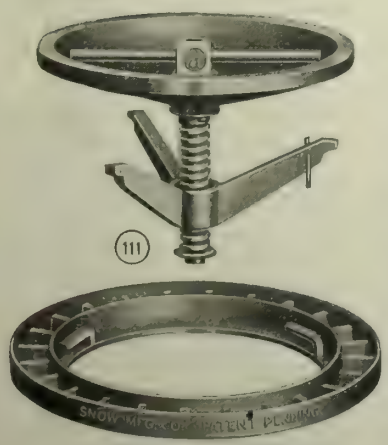
Permit No. 2508, Application No. 4141 (San Joaquin County) Issued to Mossdale Farms, Inc., Lockeford, Calif., May 26, 1926, for 3.75 cubic feet per second from Mokelumne River in Section 30, T 4 N, R 8 E, Section 26, T 4 N, R 7 E, for stock watering and irrigation of 300 acres near point of diversion.

Permit No. 2509, Application No. 4142 (San Joaquin County) Issued to N. H. Locke Company, Lockeford, Calif., May 26, 1926, for 4.19 cubic feet per second from Mokelumne River in Section 26, T 4 N, R 7 E, for stock watering and irrigation of 335.35 acres near point of diversion.

·SNOW·
IRRIGATION APPLIANCES



SNOW APEX GATES



Snow Ideal Alfalfa Valve

Good business judgement dictates, for your irrigation system, standard equipment manufactured by a long established concern with years of experience.

SNOW IRRIGATION APPLIANCES represent the highest type of modern irrigation devices, combining lowest cost with highest efficiency.

They are *standard* in every respect.

Fully guaranteed in every detail as to working effectiveness and structural defects.

IRRIGATION PIPE

Buy it for service —Indefinitely

Buy Montague Steel Products—as an investment: just as you would a tractor. You can expect and you'll get years and years of perfect service.

Montague is a name to stand by—because for 75 years we have been standing back of every **Montague product.**

Write for these booklets

Montague Well Casing.....5-A
Riveted Steel Pipe.....5-B
Surface Irrigation Pipe.....5-C

Also Oil and Water Tanks—Siphons—Stacks and Flumes—and a genuine safety water tube boiler, 1 to 20 h. p., and up.

Prices upon application.

MONTAGUE PIPE & STEEL CO

San Francisco California

More than just a stopping place; a central point from which you enjoy most thoroughly all San Francisco's attractions—the beautiful Plaza overlooking Union Square.

Post St. at Stockton
SAN FRANCISCO

Permit No. 2510, Application No. 4398 (Calaveras County) Issued to Theo. Ostermann, Wallace, Calif., May 26, 1926, for 1.06 cubic feet per second from Mokelumne River, in Section 9, T 4 N, R 9 E, for irrigation of 85 acres near point of diversion. Estimated cost $10,000.

Permit No. 2511, Application No. 4474 (Calaveras County) Issued to Theo. Ostermann, Wallace, Calif., May 26, 1926, for 1.06 cubic feet per second from Mokelumne River in Section 9, T 4 N, R 9 E, for irrigation of 85 acres in Section 9. Estimated cost $10,000.00.

Permit No. 2512, Application No. 4400 (San Joaquin County) Issued to Terminous Farms Company, Stockton, Calif., May 26, 1926, for 4.96 cubic feet per second from South Fork of Mokelumne River in Sections 1 and 2, T 3 N, R 4 E, for irrigation of 397.5 acres near point of diversion. Estimated cost $5,000.00.

Permit No. 2513, Application No. 4405 (San Joaquin County) Issued to M. H. Steely, Clements, Calif., May 26, 1926, for 0.44 cubic foot per second from Mokelumne River, in Section 10, T 4 N, R 8 E, for irrigation of 35 acres in Section 10. Estimated cost $2000.

Permit No. 2514, Application No. 4901 (Yolo County) Issued to Frank L. Fisher, Sacramento, Calif., May 28, 1926, for 22 cubic feet per second from Sacramento River in Section 27, T 11 N, R 3 E, for irrigation of 990 acres near point of diversion. Estimated cost $5500.00.

Permit No. 2515, Application No. 4902 (Yolo County) Issued to Frank L. Fisher, Sacramento, Calif., May 28, 1924, for 8.12 cubic feet per second from Sacramento River in Section 36, T 11 N, R 3 E, for irrigation of 650 acres near point of diversion. Estimated cost $900.

Applications Filed

Among the applications for permit to appropriate water filed with the State Department of Public Works, Division of Water Rights, (California) during the month of May were the following:

Application No. 5007 (Stanislaus County)—John C. Droge, Tracy, San Joaquin County, Calif., for 10 cubic feet per second from San Joaquin River tributary to Suisun Bay. To be diverted in Section 14, T 4 S, R 7 E, M.D.M., for irrigation purposes on 800 acres in Sections 14, 15, 22, 23 and 28, T 4 S, R 7 E, M.D.M.

Application No. 5009 (Butte County)—F. H. Smitton, Box 117, Gridley, Calif., for 3 cubic feet per second from Hamilton Slough, Main Canal Reclamation District No. 833, tributary to Sacramento River. To be diverted in Section 36, T 18 N, R 1 E, M.D.M. for irrigation purposes on 128 acres of rice and 74 acres of general crops in Section 36, T 18 N, R 1 E, M.D.M.

Application No. 5010 (Butte Couny)—F. H. Smiton, Box 117, Gridley, Calif. for 2.35 cubic feet per second from Lateral "E," or Shaffer Slough tributary to Sacramento River. To be divered in Section 36, T 18 N, R 1 E, M.D.M., for irrigation purposes on 94 acres of rice in Section 36, T 18 N, R 1 E, M.D.M.

Application No. 5014 (Santa Barbara County)—F. W. Mathiessen, c/o Frank C. Prescott, Atty., 145 South Broadway, Los Angeles, Calif., for 1.25 cubic feet per second from Hot Springs Creek tributary to Santa Ynez River. To be diverted in Section 11, T 5 N, R 29 W, S.B.M., for irrigation and domestic purposes on 230 acres in the San Marcos and Tequepis Grants.

Application No. 5018 (Trinity County)—Viola A. Dailey, Burnt Ranch, Calif., for 1.25 cubic feet per second from Panther Creek tributary to New River. To be diverted in Section 12, T 6 N, R 6 E, H.M. for irrigation purposes on 100 acres. Esimated cost $3000.00.

Application No. 5019 (Trinity County) Charles F. Willard, 416 Fay Bldg., Los Angeles, Calif., for 25 cubic feet per second from North Fork Trinity River tributary to Trinity River. To be diverted in Section 13, T 35 N, R 12 W, M.D.M. for mining purposes in Sections 19, 20, 29, 30, 31 and 32, T 34 N, R 11 W, M.D.M. Estimated cost $30,000.00.

Application No. 5025 (Amador and Calaveras Counties)—City of Stockton, Stockton, Calif., for 60 cubic feet per second and 30,000 acre feet per annum from Mokelumne River tributary to San Joaquin River. To be diverted in Section 26, T 5 N, R 5 W, M.D.M. for municipal purposes in City of Stockton.

Application No. 5031 (Sacramento County)—Mary A. Deterding, c/o Albert Givan, 2175-35th St., Sacramento, Calif., for 5 cubic feet per second from American River, tributary to Sacramento River. To be diverted at, or any points between Section 22, T 9 N, R 6 E, M.D.M. and Section 28, T 9 N, R 6 E, M.D.M. for irrigation purposes on 411 acres in San Juan Grant. Estimated cost $3500.00.

Application No. 5032 (San Benito County)—W. A. Pack, Hollister, Calif., for 2000 acre feet per annum from Arroyo Dos Picaches Creek tributary to Pajaro River. To be diverted in Section 15, T 12 S, R 6 E, M.D.M. for irrigation purposes on 1000 acres in Rancho San Joaquin.

Completes Eastern Trip

Roy R. Hansen, Pacific Coast Manager of the Commercial Acetylene Supply Co., Inc., has just returned from a three weeks' trip to the Atlantic seaboard where he visited the home office of his company in New York City and spent several days in a thorough inspection of the plants at Bound Brook, New Jersey, and Blue Island, near Chicago. Mr. Hansen reports that his company's plans for expansion during the next year include an even greater sales activity on the Pacific Coast.

Work Starts on Big Dam

Construction work has been begun on the main dam of the $3,325,000 Arizona project officially known as Maricopa County Irrigation District No. 1, twenty miles northwest of Phoenix. One hundred men are already working on the job, it is reported, and this crew will soon be increased to a working force of three hundred, under the Carl Pleasant Company, contractors. The dam will impound water for the irrigation of 40,000 acres of very fertile Arizona land, and will be two years in building. It will be 1700 feet long, 171 feet high from the river bed, and of multiple-arch construction.

OREGON

Fred S. Lindau of Muline, covering the appropriation of water from unnamed springs for irrigation of 10 acres in Clackamas County, and for domestic purposes.

City of Wheeler, covering the appropriation of water from East Branch of Gervaiz Creek for municipal use in Tillamock County at an estimated cost of $1000.

G. A. Miller Drainage District No. 1 of Salem, covering the appropriation of water from drainage canal of G. A. Miller Drainage District in Marion County. No estimate given.

George W. Botts of Portland, Oregon, covering the appropriation of water from unnamed stream and springs for irrigation of 10 acres, for 5.5 theoretical horsepower, domestic use and fish culture in Lincoln County, at an estimated cost of $2500.

The Oregon Iron & Steel Company of Portland, covering the appropriation for springs for irrigation of 55 acres in Washington and Clackamas Counties, and for domestic use, at an estimated cost of $1400.

Oswego Lake Water, Light and Power Company of Portland, covering the appropriation of water from Bryant Spring, Goodin Spring in Clackamas County for domestic use and irrigation in Clackamas County, at an estimated cost of $34,000.

U. S. Bureau of Reclamation covering the appropriation of water from Malheur River for irrigation and power.

David G. Glass of The Dalles, covering the appropriation of water from White River for irrigation of from 5000 acres in Wasco County, at an estimated cost of $1,000,000.

David L. Reed and John Bookout of Enterprise, for irrigation and supplementary irrigation of 80 acres in Wallowa County, from Wallowa River, Hurricane Creek and unnamed streams.

Anah Jennings of Joseph, covering the appropriation of water from Wallowa River for irrigation of 10 acres in Wallowa County.

Frank Lam of Mosier, covering the appropriation of water from Mosier Creek for irrigation of 5 acres in Wasco County, at a cost of $500.

Wm. J. F. Ashwood, C. L. Favorite and John B. Christenson of Haines, for the appropriation of water from Favorite Slough or Stock Reservoir for irrigation of 207½ acres in Baker County, at an estimated cost of $25, and John B. Christensen applies for water for an additional amount for the irrigation of 78 acres.

Dorsey F. Baker of Walla Walla, covering the appropriation of water from South Branch of Nud Creek and three developed springs, for irrigation of 38½ acres in Umatilla County, at an estimated cost of $30.

William M. Coleman of McMinnville, covering the appropriation of water from Baker and Berry Creeks for irrigation of 15 acres in the County of Yashill, at an estimated cost of $175.

Wm. J. Faubion of Faubion, covering the appropriation of water from an unnamed spring, for domestic supply for a town in Clackamas County, at an estimated cost of $3,000.

H. W. Beocher of Enterprise, covering the appropriation of water from Hurricane Creek for irrigation of 10 acres in Wallowa County.

Huntington Park
Calif.

IT'S THE *BOTTOM OF THE WELL* THAT COUNTS!

A great NEW principle for pumping water has been evolved. The advantages of the air-lift have long been recognized.

The idea of an air-driven turbine *pump*, however, combining every advantage of the ordinary air-lift—with its marked economies of cost and upkeep—is now a practical reality.

No more sand troubles—no more expensive repairs and shutdowns. All parts requiring attention or repair are *on the surface*. Cut at left tells the story. Agents wanted in open territory. Send for literature.

AMONG OUR CONTRIBUTORS

Editorial Jottings About Current and Forthcoming Feature Articles, Dealing With Practical Problems of Hydraulics, and the Men Who Have Written Them

GEOGRAPHICAL breadth, if nothing more, is achieved by this issue. Look at your map of the United States and its possessions, and measure the distance from Oklahoma, in the middle of the continent, to the Hawaiian Islands, those dots in mid-Pacific. It is a long, long way, but irrigation is the basic interest affecting the agriculture of both sections and all the territory lying between. This issue spans the distance between the two points by its articles "Oklahoma is Waking Up to Its Conservation Needs" and "Irrigation Under Tropic Skies."

How irrigation is making the west a center of cotton-growing; how the Indian Irrigation Service is accomplishing its purposes; and a large number of other articles on various phases of the industry serve to emphasis the width and breadth of the subject.

H. N. CARROLL, who tells what the growing cotton industry means and is coming to mean to the San Joaquin Valley, and what part irrigation plays in that industry, was born at Carthage, Missouri, and received engineering training at the Missouri School of Mines. His experience includes engineering service for various mining and oil companies in Missouri, Tennessee, Texas and Arizona, three years in Mexico and two years in Colombia, South America, in engineering projects. In 1922 he came to the San Joaquin Light & Power Company, Fresno, California, as a sales engineer. His service for that organization involves the conduct of economic and business research studies in the various fields touched by its activities.

E. E. BLAKE is by training an attorney, by preference a conservationist, and by official position chairman of the board of commissioners of drainage, irrigation and reclamation for the state of Oklahoma. By heritage he is a pioneer, his ancestors having had places of importance in the stirring events of the American revolution, and his father being one of the early developers of the middle west. It is quite fitting, therefore, that he should assume a pioneer position in the conservation movement of his own state. He was born and spent his early life in Ohio, living on the Ohio river, where his attention and interest were first aroused to the importance of flood control. In 1889 he came to Kansas, and from there to El Reno, Oklahoma, where he practiced law in association with his brother, the late Judge C. O. Blake, until 1910, in the latter year moving to Oklahoma City. He was largely responsible, through his legislative influence, legal ability and acquaintance with flood control problems, for the passage of Oklahoma's laws affecting drainage and reclamation, and in 1925, when the legislature created a commission to assume the responsibility for state development along these lines, Mr. Blake was appointed its chairman. He is also chairman of the interstate commission of the Arkansas River States, in charge of the investigations into methods of controlling that stream and its tributaries.

RAY J. LYMAN, author of the article descriptive of the status of irrigation in the Hawaiian Islands, has been identified, in various capacities, with irrigation projects of the west during the greater part of his life, and spent four years (1910-1915) with the United States Irrigation Investigations, working on problems of research in duty of water. He was born in Michigan, but came west to Idaho in 1890, and was graduated in 1914 from the University of California. He has been president of the Great Western Meter Company, of Oakland, California, since its incorporation, and while his primary interest in irrigation is now in the metering of water, he nevertheless preserves a vital and lively concern for all constructive phases of the industry.

LESTER M. HOLT was graduated with B. S. C. E. degree from Columbian (now George Washington) University in 1902, and one month after the passage of the national reclamation act, in 1902, was appointed to the U. S. Geological Survey, in which he spent several months engaged in stream-gauging work, and was transferred to construction surveys in Colorado in the same year. He has been in government hydraulic work continuously ever since; attached in various capacities to the Uncompahgre reclamation project, geological survey work in Oklahoma, the Truckee-Carson project and other centers of government reclamation activity. He has been active in irrigation surveys, water works construction, office and designing engineering and in practically every technical phase of irrigation work. In 1904 he was transferred from the reclamation service to the U. S. Indian Office as irrigation engineer in charge of the Irrigation Section, and in 1912 became superintendent of irrigation in District No. 1, which included Washington, Oregon, Northern California and Northern Idaho. In 1918 he was made Supervising Engineer, which post he still holds.

R. F. GOUDEY, who discusses the chlorination of irrigation supplies and their use in domestic systems, is resident engineer in Los Angeles for the California State Board of Health. He was graduated in 1917 from the Massachusetts Institute of Technology, with the degree of Bachelor of Science in Sanitary Engineering, and in addition to his work with the California State Board of Health has had experience in general construction work in the east and service in the army during the late war. He has been in Los Angeles and resident engineer for the past five years. His duties include investigations of water supplies, sewage disposal and swimming pools under the provisions of the state laws dealing with these subjects.

HYDE FORBES has been introduced to the readers of this magazine in a previous issue. His article is the second and concluding installment of an interesting discussion of the need for specialization in ground-water studies. HANKINS & HANKINS are regular contributors, conducting the department on legal and judicial matters in each issue. HARDY W. CAMPBELL was formerly connected with the Southern Pacific Railway as farm advisor and colonizing agent.

W. M. MERTZ, whose article deals with "Getting the Most Out of Every Furrow," is a well-known southern California citrus grower. The first part of his article was printed in the May issue, and the two instalments together make up a paper which he recently presented to the citrus institute. Every other article in this issue was written especially for and appears exclusively in MODERN IRRIGATION.

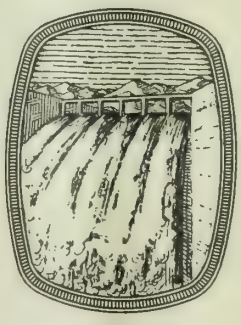
PETROLEUM WORLD 626 S. SPRING ST., LOS ANGELES, CALIF. MODERN IRRIGATION

R. V. MEIKLE

Who has tendered his resignation as chief engineer of the Exchequer project of the Merced Irrigation District after successfully carrying through the task for which he was appointed in 1924. In the construction first of the Don Pedro Dam and subsequently of the Exchequer Dam, of which he tells in this issue, Mr. Meikle has proven himself to be one of the outstanding younger engineers of the industry. He has been fortunate in having associated with him as consulting engineer A. J. Wiley, who is recognized as one of the greatest living authorities on dam design.

MODERN Irrigation
The Magazine of Applied Hydraulics



Volume II JULY, 1926 Number 7

The Progress *of* Irrigation

VIRTUALLY completed since early May, the Exchequer Dam, of the Merced Irrigation District, California, was given its formal dedication on June 23rd, and one more titanic accomplishment of large-scale irrigation development was added to the West's great record.

The attention which the Exchequer project, from the inception of activities, has commanded from the irrigation industry has been world-wide. Each step in the planning and execution of the entire task—in which the dam was only one important unit—has been carefully followed by engineers and executives throughout the irrigation country, and the completion of the work, under circumstances more than creditable to all responsible in any degree, marks an accomplishment which is not alone a triumph for the Merced district and for those who had an active part in it, but for *all irrigation.*

It is for this reason—because the entire industry shares in the honor and in the congratulation upon this big job well done—that MODERN IRRIGATION devotes a large proportion of this issue to telling the story of the Merced district, the Exchequer project, and the big dam which is its most impressive feature.

The broad outlines of this project which has just been materialized by a happy combination of engineering skill, administrative intelligence, and modern facilities of construction were conceived even before the formation of the Merced Irrigation District in 1919. Shortly after the district was organized, J. D. Galloway, a consulting engineer, made a careful survey of the district and submitted a comprehensive report to the directors. His general plan, with few notable exceptions, has been followed in the subsequent developments.

In 1924, the intervening years having been devoted for the most part to building up a working organization in the district and to developing a distributing and drainage system, work got under way for the storage units of the project. A. J. Wiley, an experienced engineer whose skill in dam design is probably more widely recognized than that of any other living authority, was retained by the district as consulting engineer; R. V. Meikle, an engineer whose work on the Don Pedro dam of the neighboring Turlock Irrigation District, had demonstrated his ability as a directing force

behind the technical work of a project of large proportions, was employed as chief engineer, and Ross White and R. W. Shoemaker, respectively, were chosen as resident engineer and electrical engineer.

Only the broadest outlines of the mammoth task which has been accomplished since the contract for the dam was signed, in August, 1924, can be suggested within the compass of two brief articles such as are presented in this issue; but some of the truly remarkable photographs which accompany the articles reinforce and supplement the written word so that the reader may gain some impression of the real significance of this undertaking.

Without much to-do, the dam has been built, the railroad has been relocated, the ten millions of dollars have been spent and the job has been finished. The engineers whose task began and ended with the construction work have tendered their resignations, which have been accepted, and a new operating organization has been selected by the directors of the district.

A suggestion of the immensity of the Exchequer Dam. This view of the temporary railroad tunnel during construction does not show the extreme thickness of the dam, however, at its base.

THIS MAGAZINE would not attempt to allot credit for the success of the project to the various individuals who deserve it. The execution of such an enterprise, of course, is no one-man job. While such men as the consulting engineer, the chief engineer, the resident egineer, the contractors, the superintendent, and others who occupy positions of key responsibility, are entitled to praise and congratulation without stint, so equally are those whose contributions, though less spectacular, are just as essential to success—the chainman on the surveying crew, the brawny, sweating laborer who was only a number on the pay-roll, the group of bond companies and the investors whose manifestation of confidence in irrigation made possible the marketing of the Merced district's securities.

The district was fortunate in having, for its governance during such a momentous period, a board of directors composed of such men as C. E. Kocher, president, E. V. Givens, Dr. C. L. Garvin, D. K. Barnell, and George Bloss, Jr. These men have directed the district through a most difficult undertaking. They carried large responsibilities and made significant decisions in unfamiliar and unexpected stuations, and did it all with sound judgment, good will, and unanimity of opinion.

Cordial relationships and co-operation between the irrigation district and the private corporations with which it was obliged to work brings into the equation still another group of men deserving of mention, and so on, from one to another in an ever-widening circle, until it seems that the project is the product, as well as the pride, of the entire industry, and a monument to what irrigation as a social and economic force has been able to accomplish in this year of grace 1926.

Exceptional and remarkable in its way as any of the engineering or structural accomplishments of the the project is the record of financial independence which the Merced Irrigation District has established. The district has financed this immense project, with the added burden of relocating a railroad, costing as much as the dam and power-house combined, without asking for outside aid from any governmental source. Its total outstanding bonds amount to $16,250,000, marketed in a business-like, orderly fashion.

The contractors on other phases of the job than the dam and powerhouse were: F. Rolandi, railroad relocation; U. S. Steel Products Company, bridge design and erection; Davis Heller Pierce Company, excavations and construction of bridge piers and abutments.

A GRAPHIC COMPARISON

These two photographs show what engineering and building skill accomplished at Exchequer in less than two years. BELOW: The site of the dam and power house in August, 1924, with the proposed dam outlined. ABOVE: The job as it appeared in May, 1926, with only the finishing touches to be added. The water had already risen in the reservoir to within 50 feet of the top of the dam, and the powerhouse was generating power for sale by the district to the San Joaquin Light and Power Co.

The Story of the *Exchequer* Project

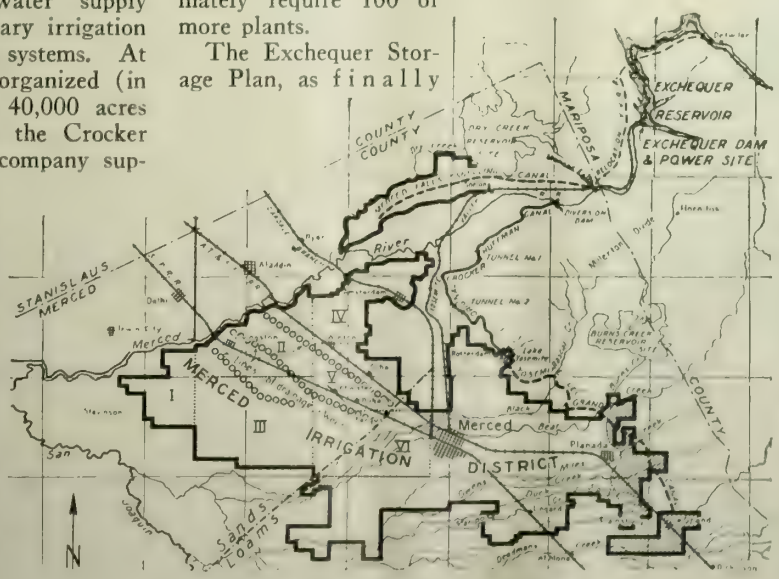
By R. V. MEIKLE

Chief Engineer of the Exchequer Project

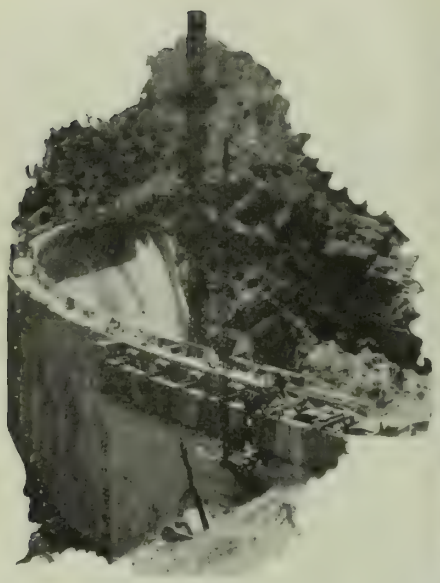
THE OBJECT of the formation of the Merced Irrigation District was to secure for its lands a full and dependable water supply and to provide the necessary irrigation distribution and drainage systems. At the time the district was organized (in 1919) an area of about 40,000 acres was being irrigated from the Crocker Huffman System. This company supplied water under contracts and the lands served were dependent upon the natural flow of the Merced River and received very little water after the first of July of each year.

The Merced District purchased the Crocker Huffman system and extended the canals and laterals to cover the entire area of 190,000 acres within its boundaries, providing for delivery of water to each 160-acre tract. A plan of drainage by pumping from wells was adopted, and 35 pumping plants were installed as the initial unit of a plan that may ultimately require 100 or more plants.

The Exchequer Storage Plan, as finally adopted by the directors of the district, provided for the construction of a concrete dam at Exchequer to impound and regulate the flow of the Merced River, for the purposes of irrigation and power, and for the construction of a power plant at the base of the dam having an average estimated output of 120,000,000 kilowatt hours yearly. To carry out this storage plan made it necessary to remove the Yosemite Valley Railroad from the reservoir site and to relocate it above the proposed high water elevation. Negotiations with the railroad company proved difficult, and the company's claim was finally settled by arbitration in November,



The Merced Irrigation District showing relation of Exchequer Reservoir to other units.



1923. The district built the seventeen miles of relocated line and, in addition, paid to the railroad the amount of the arbitration board's award—approximately $373,000.

Features of Dam

The Exchequer Dam is of the solid gravity type, arched in plan. The maximum height from stream bed is 325 feet with a thickness of 228 feet at the base and 12 feet at the top. The total crest length along the axis is 943 feet on a radius of 674 feet. A 16-foot roadway is provided on top of the dam. Mass concrete in the dam amounted to 360,000 yards, in the spillways 22,000 yards, and in the power house 8600 yards

Two sluiceways, 60 inches in diameter and steel lined, pass through the dam near the base, each controlled by one oil pressure sliding valve and one balanced needle valve, discharging from the down stream face of the dam at the side of the power house. The capacity of each sluiceway is 1000 second-feet with 125 foot head.

Two penstock openings, 96 inches in diameter and steel lined, pass through the dam to the turbines in the power house, and "Y" branches in the penstocks provide by-passes around the turbines. The penstocks are each controlled by one oil pressure sliding valve and one needle type penstock valve inserted in the penstock just ahead of the turbine. Each by-pass is controlled by a 96-inch needle-type free discharge valve imbedded in the down stream wall of the power house. The flow through each penstock is about 800 second-feet under maximum operating conditions.

An overflow type of spillway is provided at each end of the dam and each spillway is controlled by 7 14-feet by 24-feet plate steel gate leaves on steel frames with cast steel shafts and operated from a car on top of the dam equipped with a 20 horsepower motor. A concrete spillway channel from each end of the dam discharges spillwater into the river 150 feet below the power house. The total spillway capacity is 70,000 acre feet.

The contract for the Exchequer Dam included the building of the power-house, which is a reinforced concrete building 70 feet by 100 feet in plan and 90 feet high. Installed in the power house are two variable-head vertical turbines rate 17,800 horsepower at 240-foot head, but proportioned mechanically to withstand operations with full gate at 300 foot head. Each turbine drives a 15,650 K. V. A. 11,000-volt, three-phase generator at 257 R. P. M. These machines are fitted with direct-connected exciters and can be operated with safety on a basis of 70° rise in which case they will handle 18,700 K. V. A. each. The generators are connected to a single bank of step-up transformers by which the voltage is raised to 120 K. V. for deliveery to the San Joaquin Light and Power Company.

The finished dam, almost ready for dedication. The height of the dam above stream level is 320 feet, and the total pourings of concrete aggregated 374,000 cubic yards. The temporary opening left for the railroad is visible at the left. ABOVE: A side view of the dam nearing completion. BELOW: M. H. Slocum (left) job superintendent, and A. J. Wiley, consulting engineer, looking over the job.

Railroad Job Most Difficult

The relocation of the Yosemite Valley Railroad was the greatest obstacle in the way of the successful completion of the project. The old line of railroad followed close to the river and the relocated line for the greater part of the seventeen miles was directly above, making heavy shooting dangerous to the lower road where as many as twenty trains daily were operated throughout the construction period.

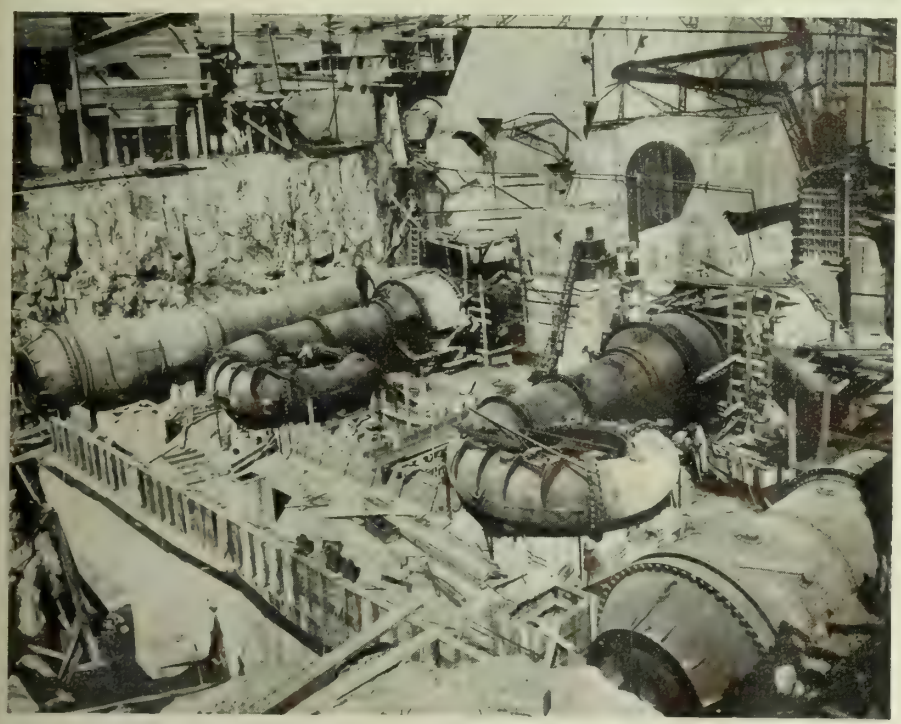
The building of the relocated line required the excavation of 1,509,078 yards of material mostly classified as rock, and the driving of four tunnels,

totaling 3,700 feet in length. Two timber trestles and five steel bridges were erected. Arches, culverts, fencing, telephone lines and station buildings completed the construction items.

The yardage excavated in railroad grading exceeded preliminary estimates by 50 per cent, making it necessary to double-shift the seventeen steam shovels to complete the work on time. All reasonable precautions were taken in carrying out this work, and as a result there were very few delays to the traffic on the main line below, in spite of the difficulties presented by the relationship of old and new locations.

truss spans carried on seven concrete piers. The two highest piers are 229 feet and 214 feet above their foundations. The bridge was erected in the remarkable time of three months.

After the three girder spans at the east end of the bridge were placed, a temporary bent was erected under the second pannel point and the first two pannels of the truss completed to this point. Two more pannels were then cantilevered and



Power house equipment being installed at Exchequer. The power house and dam were built under one contract and were rushed to completion with the purpose of supplying power and irrigation water for the 1926 season. ABOVE: A progress photo showing the dam before the power house was started. BELOW: Building the bridge, a part of the railroad relocation job. The center pier of this bridge is 228 feet high.

The rock conditions in the tunnel work provided another unpleasant surprise. They were not as good as expected, and it was necessary to timber and lag practically the entire length. The excavation was carried on by the heading and bench method and the tunnels were concrete-lined throughout, the timbering being left in place. Steel forms were used except on curves and the concrete was placed with a "concrete gun."

Interesting Bridge Job

The relocation of the Yosemite Valley railroad involved the crossing of the reservoir six miles above Exchequer Dam. The bridge at this point is 1600 feet long, made up of four 80-foot deck plate girder spans and four 315 foot

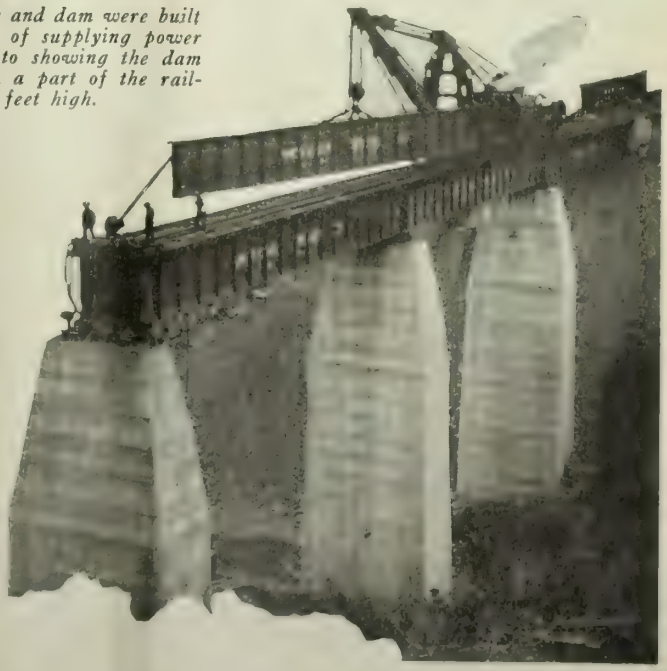
another temporary bent was erected under the fourth pannel point. The remaining six pannels of the first span were then completed to the next pier. For the remaining three spans the first temporary bent was eliminated, the cantilever being run out four pannels using the span behind for an anchor arm.

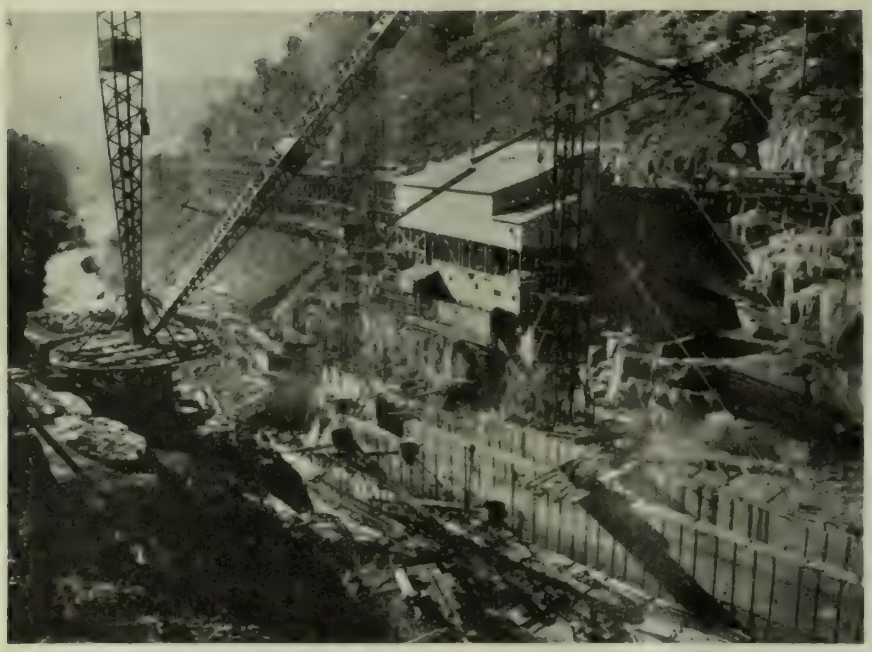
The four other bridges erected are deck plate girder spans crossing gulches running into the Merced River and average 340 feet in length. The girders are 40 to 110 feet long and are supported on concrete piers, the maximum height being 100 feet. All five bridges were erected from the new railroad which, on account of the short time available, made it necessary to construct from both ends of the railroad to the bridge across the reservoir.

Concrete Plays Big Part

Concrete represented one-third of the construction cost of the Exchequer Project. A laboratory for testing aggregates and concrete was maintained at Exchequer Dam and daily tests were made. Sand, gravel and cobbles were

(*Continued on Page 43*)





A typical scene of activity on the Exchequer Project, completed and dedicated in June, and expected to stand as a monument to the accomplishments of modern structural skill.

How the *Big Dam* Was Built in Record Time

Arthur Bent and his Brother, Stanley Bent, Tell the Story of the Construction of the World's Highest Dam at Exchequer

In an Interview with

DOUGLAS G. McPHEE

PLAN YOUR work—then work your plan. That's the secret of success in building big dams, according to Arthur S. Bent and Stanley Bent, the two brothers who comprise Bent Brothers, general contractors, and who are known as builders of great irrigation structures wherever water is impounded by concrete.

The maxim applies to many other things besides the building of irrigation works, and if this were an article for a magazine of the "inspirational" type, many excellent morals might be elicited from the experience of the Bent Brothers in this big job, based on their conclusion that the important thing in achieving such an undertaking is to lay the ground-work *right*—to have the best possible plan to follow it without deviation.

How It Worked at Exchequer

But irrigationists are more concerned in how this applies to the particular job in hand, the construction, in record time, of the highest dam in the world, built to serve 181,000 acres of California land by impounding in an excellent natural reservoir site the flow of the Merced River.

Each Dam Special Problem

"Dam construction is different from ordinary building work," says Stanley Bent, who has been in close contact with the Exchequer project from the time the first surveys were made looking toward submitting a bid on the job, "in that each individual dam presents a unique problem. There are no two alike, and hardly ever, in large projects of this kind, do they have many points of similarity. In ordinary construction work—in putting up an office building, for instance—the same thing is done in the same way until the general outlines of the task become pretty well standardized. The contractor must consider whether the haul of materials is a long one, requiring a railroad, or a short one, which can be economically handled by truck; and there are similar details to be determined for each different job; but in the erection of a dam, every detail must be planned for the particular task. Because of this *individuality* of dam construction, the most important thing in the whole job is the matter of planning."

"And this same matter may be looked at from another standpoint, equally important," added Arthur S. Bent, president of the contracting firm, formerly president of the Associated General Contractors of America, but perhaps better known in Los Angeles, his home, as president of the Los Angeles Chamber of Commerce. "So large a factor in the total cost of a job of this kind is the plan upon which it is all based—the lay-out of the plant and the method of integrating the various operations into one smooth-running machine—that the letting of the contract will, in fact, often depend very largely on which bidder has conceived the *one* right, logical, efficient plan and figures his estimates on that basis.

"It becomes doubly necessary, therefore, to get the ideal plan before anything else is done. If the contractor does not have that plan to work on, some one of the competing bidders undoubtedly will, and, with a more efficient basis of operation, will submit a lower bid and get the contract. If the contractor does have the best plan, and is awarded the contract in consequence, any change from that plan later will weaken his efficiency and lessen his margin of profit."

Cramped Quarters

How this fact was exemplified in the Exchequer dam was explained by the brothers Bent as they sat across from me in their modest office on Pecan Street, in Los Angeles, the little building from which some of the West's best examples of irrigation engineering have been directed, including the Sweetwater Dam, Lake Hodges Dam and Henshaw Dam in San Diego County, Devil's Gate Dam, San Dimas Dam and Little Rock Creek Dam, Los Angeles County, and Bullard's Bar and Kennedy Dam, in Northern California.

In this particular problem, the construction plant had to be built to fit

the narrow canyon already occupied by the Yosemite Valley Railroad. The railroad had to be kept in continuous operation during the construction of the dam. At the same time a new road was being built higher in the canyon, and while the dam was being built around the track both the operation of the road and the progress of the dam had to be maintained absolutely on schedule.

A Complicated Problem

Such a situation naturally complicated the method of operation, even after the best plant lay-out was selected, the contract awarded and signed, and work commenced. It was not feasible to store, in the space available, more than one day's supply of aggregate, or two day's supply of cement. (One day's supply of materials is not such a negligible quantity, be it understood, when concrete pourings are running around two thousand cubic yards per day).

In the face of such problems, it was the more remarkable that the contractors devised the plan that afforded an efficient system of operation, and not only overcame the difficulties, but handled one of the world's largest concrete jobs in record time.

STANLEY BENT

Bent Brothers' work on the Exchequer project included more than the building of the dam alone. The construction of power house—a sizeable task in itself—was part of the same job, and the contract involved also the delivery of all aggregate required in the railroad relocation, for concrete piers, tunnel lining, and ballasting roadbed.

"The record for prompt completion of this big job, is one of which we are very proud.

Water Needed Early

"Our contract with the irrigation district was signed August 12, 1924. The imperative need of haste, of course, was dictated by the desire to begin impounding water for gravity irrigation at the earliest possible date, as well as to begin as soon as practicable the generation of power which would mean income to the district. It was hoped that the dam could be put in use for both these purposes during the 1926 season, although to accomplish that feat would require some record-breaking work on the part of all concerned.

"In May, 1926—twenty months after the signing of the contract—the flood gates of the dam, each sixteen feet wide, thirty feet high and seventy-five tons in weight, were dropped to their places behind the openings left during construction, and water began to accumulate in the reservoir. In spite of the fact that it late in the season, it looked for a time as if the reservoir would fill to a point sufficient to assure a maximum delivery of both irrigation water and power. The lake did fill to a height of 240 feet — a point only 50 feet below the top of the dam and within a short time water was going through the power-house generating electricity for sale to the San Joaquin Light and Power Company under the terms of the district's contract.

ARTHUR S. BENT

"The largest and most important part of the time-element objective was therefore accomplished. Although it will not be possible to get 100 per cent results from the dam this year in the generation of power, it will yield an abundance of irrigation water up to the full needs of the district for the season.

"While many phases of the Exchequer job involved the setting of world records—the height of the dam, for instance, (320 feet above stream level) and the height of the bridge, the center pier of which was 228 feet high, and some of the figures for daily and monthly pourings of concrete, I think that the thing we who worked with it feel the most pride in is the promptness with which it was completed—and without any sacrifice of quality of the finished structure."

Big Things Done Quietly

Big things have been going on, up there in Merced Valley, shut away from the whole world, that the average man little dreamed of. As Mr. Bent told me of the way in which the work was conducted, it seemed to me that the most impressive thing about it, paradoxically, was the matter-of-factness and quiet modesty with which it has been carried out.

"We have had a complete little city, created for the dam and existing only during its erection," he explained. "When a construction job like this is started this temporary city is the first thing that it is necessary to build. The contractors must plan this new community with the same care that is to be excercised in every other detail of the plan. They must provide not only an efficient corps of workmen, but a community in which those workers may be contented and happy during the months that they spend on the job. They must provide homes, streets, water-works, sewage system, gas and electric service, movies churches and everything that enters into the make-up of a modern city.

"In our Exchequer city we had as many as 600 resident workers in addition to forty or more families.

"In order to give you some idea of the magnitude of this work in other than mere statistical terms," said Mr. Bent, "you might consider that the total aggregate produced for the dam and the railroad structures (our contract provided for supplying aggregate for both) was 1,000,000 tons. The average load per car when this is being transported is forty tons. In other words, if the aggregate can be conceived as all loaded on one train, the imaginary train would contain 25000 cars, and would have a length of 200 miles. This way of presenting figures is not necessary for our engineering friends, but it may interest the non-technical reader.

(Continued on Page 35)

Professional Training for "Ag" Engineers in U. C. Course

By L. J. FLETCHER

Professor of Agricultural Engineering, University of California

L. J. FLETCHER

AGRICULTURAL engineering, as a distinct division of the engineering profession, has just received additional official recognition from a leading institution of higher education in the approval, by the Board of Regents of the University of California, of a four-year technical course for agricultural engineers. The University of California is the first educational institution on the Pacific Coast to offer a professional course in agricultural engineering, and there are but eight other institutions in the United States which offer similar courses.

According to the present plan, as worked out by the faculty and approved by the Regents of the University, the course in agricultural engineering will be given in the College of Mechanics, the student spending three years at Berkeley and one year at the Branch of the College of Agriculture. The work at Berkeley will be largely of an engineering nature, while at Davis the student will enroll in courses in agricultural engineering, irrigation practice, soil technology and general agricultural courses.

It is to be noted that the professional curriculum in Agricultural Engineering is not intended to train men as irrigation engineers. There is now in the University of California a Department of Irrigation. This department offers a professional curriculum in the College of Civil Engineering for men who wish to train themselves particularly for professional work in irrigation. There is also in the College of Agriculture a Division of Irrigation Investigations and Practice. This division deals with irrigation, not alone from the standpoint of methods of application of water but also from the standpoint of the soil and plant relationships. However, the graduate in the professional curriculum in Agricultural Engineering will be well fitted to superintend farm enterprises where the operation of irrigating equipment such as motors and pumps is involved.

The Agricultural Engineering Division of the College of Agriculture is receiving an increased number of requests for men who have received professional training in agricultural engineering. Manufacturers of farm machinery have established training courses in their factories for graduate agricultural engineers. The Pacific Coast is asked to supply several men each year. Other requests have come from electric utilities, educational institutions in the west, government agencies, manufacturers of farm building and machinery equipment, and large farming enterprises. Inquiries are being received from students in other institutions both in this country and abroad concerning professional undergraduate training in this field. The results of research work being conducted by various members of the Agricultural Engineering Division are tending to focus on California the attention of prospective students as well as employers of graduates. The University of Oxford, England, has established an institute of agricultural engineering and a number of German universities have organized means for study and investigation in this field.

Meets Definite Need

There is a definite need for the establishing of this new course. The more significant feature of the progress of American agriculture during the past century has been the introduction of machine methods production. The amount of labor required to produce one bushel of wheat one hundred years ago is sufficient today, by the use of modern machinery, to produce more than twenty-five bushels. Over 80 percent of the energy expended annually on California farms is furnished by electric motors, internal combustion engines, not including automobiles, and windmills. There are more tractors used per acre of improved land in California than in any other state in the union. While the California farmer expends annually about 100 horse power hours of energy per acre of improved land in producing his crops, it is quite evident that this energy is used efficiently for the average net income per farm operator in this state is over twice the average for the United States. There is also a need for better farm structures from the standpoint of efficient use of building materials and convenience.

This agricultural engineering course, as established in the University of California, contains 113 units of required work, 17 units recommended electives and 20 units free electives. The distribution by general subjects is: science, including chemistry, mathematics and physics, 24 percent; general engineering 25 percent; general agriculture 13 percent; agricultural engineering 14 percent; cultural 5 percent; military and physical education 5 percent; free electives 14 percent.

Touches Many Points

It is the purpose of the agricultural engineering curriculum to give training in engineering fundamentals, together with such agricultural subjects as will enable correct application of engineering principles to rural problems. The agricultural engineer largely concerns himself with those engineering problems which apply to the individual farm, such as mechanical equipment for the farm; the application of power to farm operations; the location, design and construction of buildings and other farm structures; water supply and sewage disposal on the farm; the sanitation, heating, lighting and ventilation of farm buildings; labor saving equipment for the farm home; land clearing; and certain phases of the manufacture of agricultural products insofar as this process is conducted on farms.

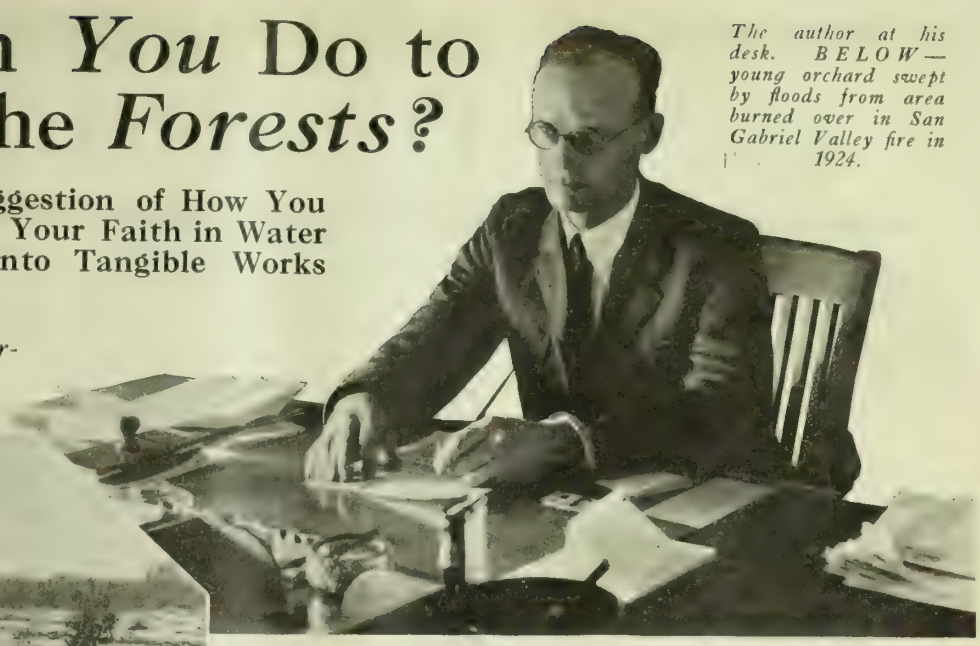
The American Society of Agricultural Engineers, which was organized twenty years ago to promote the art and science of engineering as applied to agriculture, and which held its annual meeting at Lake Tahoe in June, has contributed largely through its College Division to the building up of professional work in this subject.

The new agricultural engineering building, which is to be erected on the University Farm at Davis this summer, will provide facilities which will make possible material improvements in the courses offered by the Agricultural Engineering Division.

What Can *You* Do to Protect the *Forests*?

A Definite Suggestion of How You May Translate Your Faith in Water Conservation Into Tangible Works

By STUART B. SHOW
District Forester, U. S. Forest Service



The author at his desk. BELOW—young orchard swept by floods from area burned over in San Gabriel Valley fire in 1924.

IN THE great West we are justly proud of our highly developed and diversified agriculture. Back of that splendid agriculture lies a supply of water for irrigation without which we should never have progressed beyond the extensive grain-growing days. Water is indeed king.

Back of the water supply lie the mountain areas and the forest and brush cover which are the primary source of water control. How much is this cover worth to the water user? In a certain canyon in Southern California I am told that water is worth $30 an acre-foot. To catch 1,300 acre-feet the water users constructed a $700,000 dam, an investment of over $500 an acre-foot. In the heavy rains of last April there fell on that watershed the equivalent of 8,800 acre-feet of water, of which only 1,100 feet, or one-eighth of the total, ran off immediately. In other words, seven-eighths was held back by the cover, most of it to appear later as gradual seepage to the reservoir. Figured on an investment basis, the cover of this watershed is worth about $5,000,000, for without it, no doubt, the bulk of the rain would have run off those steep slopes at once.

Not many parts of the west can yet figure so high a value for water or for the cover which protects it. But the same problem of watershed protection exists up and down the the Sierras and Coast Range, varying only in degree.

What Can You Do?

What can the individual do to help in the forest problem, for that is the problem we must jointly solve?

First of all, he can exercise extreme personal care with fire, the enemy of the forest. In that I should include active participation in the unceasing campaign to make every individual feel a sense of responsibility for protecting the forests. The man who causes a fire is in truth an enemy to society, and it is only public pressure that will finally teach the infinitely small minority of fire causers that their activities will not be tolerated. The public agencies, however capable, can not solve the problem alone.

Everywhere in fields and forests the law says that burning matches and tobacco shall not be thrown from moving vehicles. We know it is a good law because scores and hundreds of fires are caused that way each year, but to enforce that law by direct police action is out of the question. Have you a receptacle in your car for cigar and cigarette stubs and matches, and is it second nature to use it?

On some of the most hazardous forest areas smoking is prohibited during the fire season. That again depends largely on the sense of responsibility of the individual rather than on policing. Last year a surveyor "sneaked" a smoke out in a brush patch. It finally cost some $80,000 in public funds and destroyed thousands of acres of watershed cover. Do you support the no-smoking laws and regulations?

The California lumber industry in the pine region of the Sierras and Coast Range, from which comes the water for the Sacramento and San Joaquin Valleys, cut over each year some 60,000 to 70,000 acres of forest. Part of this is on National Forest lands, where by reserving thrifty trees and saving the young growth, a forest cover is maintained. On part of the private land, on the contrary, clear cutting, the use of high-power logging machinery, and fire, leave the land with no start towards a new forest. The lumber industry would be in a far better position to take up active reforestation measures were the fire prevention activities of the state increased. Areas of young growth have a high fire hazard, and additional protection, under state leadership, is urgently needed. Because denudation of forest land is likely to affect adversely the water supply and because we need every possible acre of growing forest, the water user has a direct interest in developing a constructive state forest policy. A fine start has been made—whole hearted and aggressive action is now needed to strengthen and upbuild the fire protection machinery of the state.

Vol. II JULY, 1926 No. 7

The Exchequer Project

EXCHEQUER dam and the great project of which it is a part are more than the accomplishment of a single irrigation district; they are symptomatic of the great capacities of the industry.

This issue is so largely devoted to this project, not because the dam was the highest in the world, or because the concrete pourings set a record, or because the incidental engineering tasks were so monumental and novel, but because here again irrigation has shown itself to be "big business;" and not only that, but big business independent, self-sufficient, and solvent, commanding the respect and confidence of investors, and requiring as its right the best of technical and constructing skill from the professions of engineering and contracting.

On pages 9 to 15 (inclusive) we have attempted to give a picture of the Exchequer project which would be almost worthy of the achievement itself. No story in a few pages could hope to do the big job justice, but we have, perhaps, done as much as journalism could.

Our grateful acknowledgements are due to R. V. Meikle, chief engineer, who wrote the article on pages 11, 12 and 13; and to Arthur S. Bent and Stanley Bent, of the contracting company which built the great structure and whose account of their important part of the work is told by the editor on pages 14 and 15. These are the men who played the leading parts in the construction itself; but they, like big men generally, had time for one more thing; they responded whole-heartedly and generously to the request that they give to the readers of MODERN IRRIGATION a personal glimpse of what the Exchequer is.

A Year of Service

THE FIRST issue of MODERN IRRIGATION to come from the press was dated July, 1925; the present issue marks the completion of a year in the history of the magazine. It may not, perhaps, be inappropriate to speak briefly, on such an occasion, of what it has accomplished, and of its ambitions and plans for the future.

With its first number, it enunciated the principles on which it intended to stand—the presentation of attractive and reliable material of interest and value to men active in or directly concerned with irrigation, including both technical articles by the leaders in the practices of the industry, and other matters, of less technical nature, but of equal interest to the whole hydraulic fraternity. It promised that this material would be uncolored and unprejudiced, prepared and published in the interest of no group or faction, but actuated by the motive solely of giving an intelligible voice to the great, fundamental industry upon which the West depends—which had been theretofore practically inarticulate.

The experiences of twelve months have not changed our intentions of adhering closely to this declared program; they have rather strengthened that determination. In this year, it should have been apparent to the most casual reader that the magazine, when it asserted that it was uncontrolled and unsubsidized, meant exactly what it said. It is still, as it was in its inception, the organ of the whole industry, and not of any one part thereof.

A Broadened Scope

SOME CHANGES, of course, have been dictated by what the magazine has learned during this year of existence. It soon became apparent, for instance, that in the West there is a natural and inevitable community of interest between the irrigationist and the developer of domestic water, and a department has been instituted, on a scale which is destined to grow larger, devoted to the water companies engaged in municipal and public service.

This department it is the intention of the publishers to expand into an increasingly important part of the journal, treating to a large extent the problems which affect both water works and irrigation development, as well as certain problems peculiar to the water works field and the individual concerns of that industry.

A legal department has also been instituted, giving each month in

POINT *Of* VIEW

condensed form the outstanding judicial decisions of western courts involving matters of law germane to irrigation, reclamation, drainage, and all form of hydraulic activity. This department has a proper and necessary place in a journal such as MODERN IRRIGATION, because the steadily growing body of irrigation law is of vast interest not only to lawyers but to all executives of the industry.

Overhead Irrigation

IN the early issues of the magazine a department was included, devoted to overhead irrigation, and it has become apparent that no mistake was made in conceiving this new form of water application as worthy of a separate division and prominent notice in every issue. The desire to learn more about overhead irrigation is noticeably growing among irrigators everywhere, and responsive to this desire, the magazine has set out to enlarge and improve the overhead irrigation department, with the purpose of making it indispensable to overhead irrigators and to all who are considering overhead irrigation, as an authentic guide to what is going on in that branch of the industry.

The new overhead department is introduced in this issue. A consulting overhead engineer, whose experience and contact with overhead operations has been a particularly wide and comprehensive one, has been secured to conduct this department for our readers. A feature of the department will be a "questions and answers" column in which the reader may seek and obtain expert advice on problems of installation or operation of sprinkling systems.

News of "the Trade"

ANOTHER department introduced in this issue for the first time, which will, in the future, be a regular feature, and which should be of considerable interest to readers, is that headed "Trade Notes of the Month."

The manufacturers of irrigation and water works equipment, in their natural and necessary competition, with their research laboratories and engineers in continual practical contact with the field at all its points, are doing as much as any other agency in the advancement of irrigation practices. What they are planning and doing is of real importance to the industry.

It has been the policy of MODERN IRRIGATION from its inception not to use, in the guise of news matter, the announcements of manufacturers and dealers which in reality are but modified advertising. In "Trade Notes of the Month" our purpose will be to gain the advantages of those announcements which have value for the reader and advertiser alike, without incurring the odium that attaches to the publication which is "edited by its advertisers." The material in this one department will be frankly and undisguisedly furnished by our advertisers, and should be read with that understanding. No reader is obliged to devote his time to it unless he does so for the information which it contains, which will often be of direct and appreciable value.

Farm Prosperity

CARL E. GRUNSKY, an engineer whose name and opinions are universally respected, presents in this issue his thoughts on the question of how agricultural prosperity may be promoted (if at all) by government action. Mr. Grunsky questions the efficacy of attempts to soften the incidence of unaltered economic law, by any form of subsidy or bonus. He holds up as the only permanently effective way of helping the farmer a plan for increasing the relative number of consumers. We must, he believes, undertake large public works and spend vast sums for military and naval equipment, so that as many individuals as possible shall be removed from the producing ranks and be made consumers. "This," he concludes, "during any period of over-production, can only make for prosperity."

More space than is available for this brief note would be necessary to examine these contentions fully. It ought, however, to be said that "prosperity,"—a vague term at best—will be found to consist not in an abundance of money, nor in the rapidity of its circulation, but in an abundance of goods, widely distributed. "Over-production," too, if its meaning is not properly understood, may be a misleading term. It does not mean—it never has meant—that the mass of the social group was over-supplied with goods, but that the goods were unevenly distributed; that commodities were not moving uniformly and at a fair price from producer to consumer.

Should such a scheme for economic reconstruction be followed, it might have an effect of the kind which Mr. Grunsky predicts. The rapid circulation of money has a tendency toward promoting "better business"; prices rise, and with rising prices, a fictitious prosperity would ensue but not, of course, if new wealth also had been created, as it presumably would be by the construction of good roads and other public works.

"The relatively high taxes inherent in such a policy need not be feared," says Mr. Grunsky. "They will be collected only from those who are able to pay, and who, in their turn, will share in the engendered general prosperity." Such a system of taxation has been sought by statesmen since states were, but has not, up to now, been found. It it could be found, however, the resultant benifits might even surpass, in their effect upon the economical life of the country, Mr. Grunsky's own hope for the successful application of his plan.

W. F. McClure

THE OFFICIAL head of irrigation in the state where it has reached its highest development, W. F. McClure was a figure of importance in the world of hydraulics. He held his commanding place in the respect of his profession not by the influence of official position, however, but by the force of his own ability, character and demonstrated worth.

Wilbur F. McClure—The *Man*

As Teacher, Minister, and Public Official, California's Late State Engineer Spent His Life-Time in Modest, Unassuming Service

By PAUL BAILEY
Acting State Engineer of California

ON THE AFTERNOON of June 22 official circles at the California capital were shocked by learning of the sudden death of State Engineer Wilbur F. McClure. His long term of service, his habitual friendly greeting, and his interest in public affairs made for him throughout the state many friends who mourn his loss. Mr. McClure served his State faithfully and well in the capacity of State Engineer for fourteen years. For the past three years, he was Director of Public Works and Chief of the Division of Engineering and Irrigation. His innate modesty and quiet demeanor have left a record of service little heralded before the public, but replete with honest endeavor for the public welfare.

The life of Mr. McClure has been unusual in many respects. Educated as a school teacher, he left this occupation to engage in railway location and construction, and after several years of successful endeavor became a member of the Methodist ministry. For seven years Mr. McClure held pastorates in several sections of California, but in 1900 he returned again to the practice of his chosen profession. From 1900 to the present date, Mr. McClure was almost continually occupied in public service.

He was first connected with the removal of Arch, Blossom and other rocks in San Francisco harbor and following this became City Engineer of Berkeley and, later, Commissioner of Public Works for the same city. For three years following 1909, Mr. McClure was engaged in the private practice of his profession, but in 1912 was again called into public service by Hiram Johnson, then Governor of California. In this office, Mr. McClure was serving under appointment by the third successive Governor at the time of his death. Active until the last, Mr. McClure passed away while officially inspecting a dam site near Placerville, California.

At the time of taking state office, in 1912, the jurisdiction of the State Engineer's office related principally to work in and about state institutions, with minor enterprises in road construction and rectification of river channels. During the period in which Mr. McClure was State Engineer, however, there has been a great expansion in the activities of the office. State supervision of irrigation and reclamation development and dam construction originated and grew to large proportions during this period. Engineering investigational work became an important function of the office as well.

Between the years 1911 and 1915 the California Irrigation District Act was perfected, through many admendments, to the point that it became practical for substantial irrigation development to proceed. In 1913, the California Bond Certification Commission was created by the legislature, composed of the State Engineer, Attorney General and Superintendent of Banks. Through the separate jurisdiction of the State Engineer's office under the California Irrigation District Act and the jurisdiction of the Bond Commission, the state has supervised one of the greatest expansions in irrigated agriculture that has occurred in any locality in the United States. Since 1912, over $120,000,000 of state-approved bonds have been issued for construction work through the organization of 100 irrigation districts. The total area included in these districts in three and a half million acres, three fifths of all the lands under irrigation in California. This is a greater area than is at present irrigable under all the federal irrigation projects combined.

The assemblage of the large volume of capital at low interest rates necessary to construct the works for irrigating this vast area was made possible through the successful administration of state supervision of irrigation projects. This successful administration has made irrigation securities readily purchased by the buying public. Almost without exception, these entire areas have met their financial obligations as they became due.

This great and rapid expension of the irrigated areas in California advanced conditions to the point where organization of large areas became necessary under conditions not contemplated by the California Irrigation District Act. Accordingly the California Water Storage District Act was passed by the Legislature of 1921 and the California Water Conservation District Act in 1923. Under the supervision of the State Engineer, as provided in these acts, about two and a third million acres have organized to irrigate new lands and to improve the water supply of other lands already under irrigation.

In order that progress might continue uninterruptedly and agriculture and other industries dependent upon water might further contribute to the prosperity of the state, engineering investigational work concerning available water supplies and their most advantageous utilization became one of the most important functions of the State Engineer's office during the latest years of Mr. McClure's administration. This work produced the reports upon the Water Resources of the state presented to the Legislatures of 1923 and 1925. These reports contained the first complete inventories of the waters of California and of the future needs for water in order to accomodate the full development of the resources.

Parallel with this immense program of irrigation development, reclamation of overflow lands in the Sacramento and San Joaquin Valleys has also progressed rapidly under legislation passed in 1911. The State Engineer's office has participated with the State Reclamation Board and the California Debris Commission as provided in this legislation for the state supervision of these projects.

All this work stands as a monument to the administration of Mr. McClure, and to the vision and capacities of the man.

THE HYDRAULIC DIGEST

A Monthly Bulletin Board of Brief Facts and Events from Far and Near

Boise Project Autonomous

Transfer of the operation and maintenance of the Boise (Idaho) Reclamation project to its water uses has practically been completed by the Reclamation Bureau. The Boise project is the first of the government's large irrigation projects in the west to be turned over to the farmers for operation under the new law.

Texas Reports Optimistic

Not for many years have conditions been so good and prospects so bright for farmers and stock raisers of the southwest, according to a report from El Paso, Texas. An abundance of moisture, following the drought the past few years, has supplied the factor needed to make this a banner year for producers of the arid regions of Arizona, New Mexico and west Texas.

Settlers Will Operate District

A decision to resume operations of the Hermiston (Oregon) irrigation district was made late last month by the district's board of directors. The operations will commence shortly after the first of July. It is announced that the settlers will handle all the operations, thus cutting down the operating forces and expenses.

Earlimart Plans System

A mass meeting was held in Earlimart (Calif.) in June, to discuss ways and means of securing a town water system. District attorney McCormick, of Visalia, explained the California Public Utilities Act, whereby small towns may form a water district. Shares in the company will be sold to each lot owner who wishes to make a connection.

Colorado Outbreaks Minimized

Engineers of the Imperial Irrigation District have declared that there is no cause for alarm so far as the American Imperial Valley is concerned regarding the recent outbreaks of the Colorado River in that vicinity. There are two secondary levees that stand between the Colorado and the American Valley, and the district anticipates no trouble outside the immediate region of the inundation.

Indians Want More Water

The Indians of the Salt River reservation, numbering 823, have organized for the purpose of increasing their water allowance to an amount necessary for the proper irrigation of their three thousand acres of land now under cultivation.

More Flood Guards

A proposal that the federal government and the county share equally in the cost of safeguarding tide flats from Puyallup river floods, has been made by the Tacoma Chamber of Commerce. This proposal will be submitted to Congress through the District Engineer's office.

San Carlos Progresses

Plans and specifications for the San Carlos (Ariz.) irrigation project and dam are nearing completion and bids will be called for at Phoenix and elsewhere within the next sixty days. Government authorities have expressed the hope that the first earth on the project would be turned by the first of October at the latest.

Olympia Has More Water

Two artesian wells, delivering 576,000 gallons of water each 24 hours into the city water mains of Olympia (Wash.), were tied into the city water system recently. One of the wells delivers 175 gallons and the other delivers 225 gallons per minute. City officials assert that with this added supply, Olympia will not experience a water shortage even in the driest of seasons.

Bolinas Gets Water

The State Division of Water Rights has granted the application of the Bolinas Public Utility district for one second foot, or approximately 650,000 gallons a day, from the Arroya Honda Creek in Marin county (Calif.). The water will be used as a municipal supply for the Bolinas district, which includes the town of Bolinas and about 1000 acres of unincorporated territory. A low concrete dam and nine miles of pipe line are to be provided at an aggregate cost of $50,000.

Imperial Will Rebuild Dam

Application has been made by the Imperial Irrigation district (Calif.) for permission to repair and rebuild its temporary diversion dam across the Colorado River at Hanlon's Heading, California, for the purpose of raising the water elevation during its low-water stages sufficiently to divert the amount needed to supply the Imperial District during the season 1926-27.

Lower Court Sustained

The Supreme Court of Oregon rendered a decision on June 1, affirming the decision of the lower court and approving the sale of surplus water from the Warmsprings Irrigation District to the government for the Vale, Oregon district. The decision of the court was unanimous and was rendered by Justice Belt. It constitutes final approval of the law passed by the 1925 legislature, which made the sale of water by the district a lawful procedure.

Lomita to Vote on System

Lomita (Calif.) is preparing to hold an election, which will perhaps be called by the county board of supervisors near the middle of July, to determine whether or not a county water works district will be formed. It is estimated that the system will cost approximately $380,000, and asserted that when the plant is completed it will be among the best in Southern California, owing to the large underground flow of water which can be obtained there.

District Votes on Contract

On or about July 10, voters in the Payette-Oregon Slope Irrigation district will ballot upon the contract with the United States for their proportionate share in the construction costs of the Owyhee District. All the preliminary details of this action have been taken care of, and if the voters pass upon the contracts, all that will be necessary will be the approval of the Secretary of the Interior and the decision of the district court on the validity of the contract. It is expected that the middle of August will be reached before final action can be expected.

HYDRAULIC ENGINEERING

Dealing with the Practical Problems of the Operating and the Consulting Engineer

Taking the Temperature and Feeling the Pulse of the Test Dam on Stevenson Creek

By R. W. CARLSON

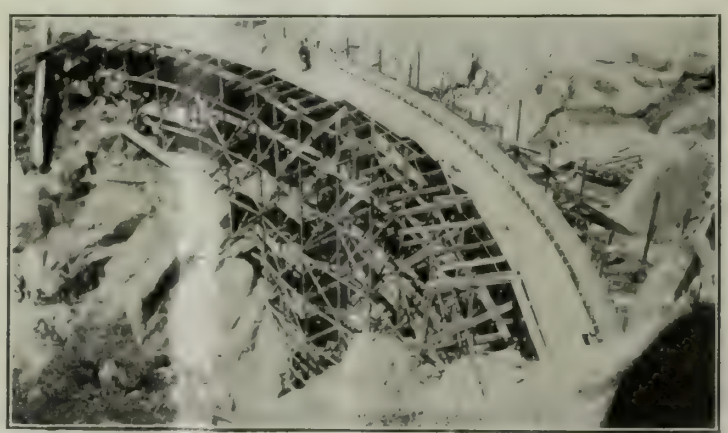
UNTIL recent years, arch dams have been designed in a very elementary way. The concrete has been assumed to carry loads without being deflected or strained and the arch has been treated as a portion of a rigid cylinder. The method for calculating the thickness of an arch section for assigned conditions has been too simple to be fascinating.

Increasing knowledge about concrete and increasing investments in arch dams has brought a flood of refinements in design. All of these refinements have been required in recognition of the well-known fact that concrete deforms. Perhaps the first of these has been to take account of the effect of temperature changes on the length and shape of the concrete arch. The second has been to include the effect of shortening and bending of the concrete arch under the water load. Next has been to compute the load carried by the vertical beam sections and reduce the load to be carried by the horizontal arch sections by this amount. Other refinements have been the analysis of the effect of lateral expansion due to load, the effect of shear, the effect of shrinkage, the effect of moisture absorption, and other important but very uncertain conditions.

Before new developments can be made standard practice, the magnitude and importance of the score of actions which shall determine rational design must be evaluated. Meanwhile, to insure safety and cover uncertainties, arch dams are presumably being built many times stronger than calculations demand.

Realizing the certain gain in knowledge and economy which will accrue, the Engineering Foundation is sponsoring a full-sized test-to-destruction of a concrete arch dam. The site is located in the steep canyon of Stevenson Creek in the Sierra Nevada Mountains sixty miles east of Fresno, California, where the storage of water will be small and no damage can result from the ultimate failure.

ABOVE: *Author reading a telemeter, one of the many instruments used in the Engineering Foundation Dam.* BELOW: *The completed dam before the forms were removed.*

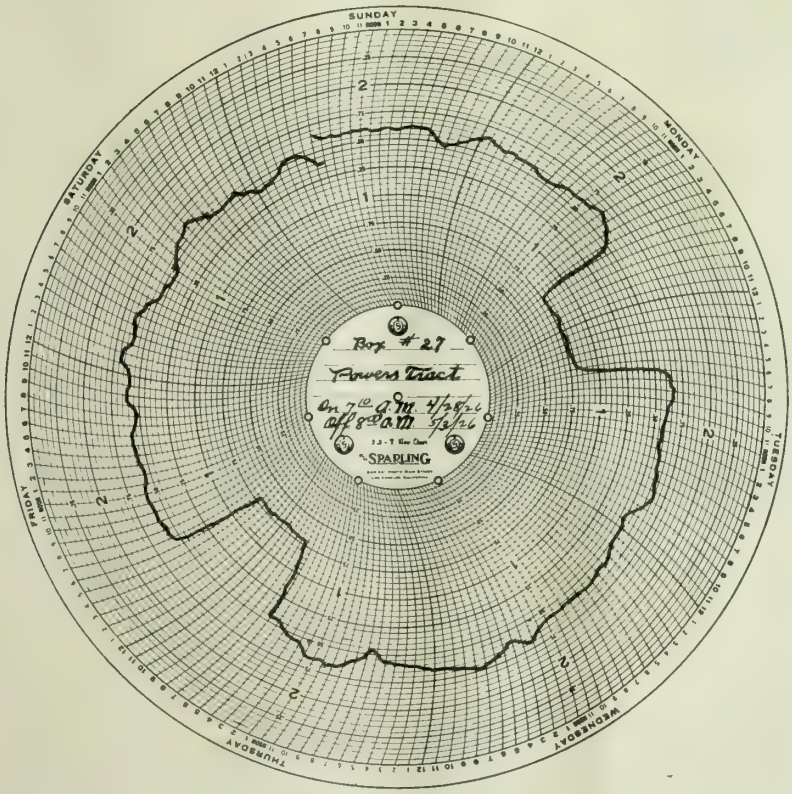


The dam has been completed to a height of sixty feet and will be tested extensively before being built higher. It is an unreinforced single arch of 140 foot crest length, 100 feet radius, seven and one-half foot thickness at the base, two foot thickness at the thirty foot level, with no change in thickness from that level to the crest. The abutments make angles of forty-five degrees with the horizontal on either side of the canyon, and the central portion of the foundation is a vertical arc of twenty-five foot radius. The concrete is uniform throughout and numerous tests of samples indicate that it is capable of supporting more than two thousand pounds per square inch.

METERS AND GAUGES

Since the distribution of stresses depends upon deformations of the concrete, elaborate preparation is made for measuring the minute internal and external movements. To measure extension or shortening, five hundred ten-inch distances (between steel plugs systematically located on the surfaces of the dam) are measured from time to time to a ten thousandth of an inch with strain gauges. The change in inclination of the downstream face of the dam are measured at sixty stations to a thousandth of an inch in five feet by a five foot vertical clinometer. The changes in curvature of the horizontal arch sections are measured at some fifty stations by means of an especially designed

"A Record That No One Can Question"



Facsimile of an eight inch water flow record chart from the new 2.5 foot range Sparling canal level Recorder.

This Recorder, with ball bearings, all-metal weather-proof case, and glass door with padlock, sells for but $50.00. It is shipped subject to thirty days approval.

change-of-radius meter. The movements of central portions of the dam upstream or downstream are measured from the sides of the canyon by means of surveyors' theodolites with telescopes of high power. Measurements are to be made to detect tilting of the foundation at five stations by placing an especially designed level bar on heavy I-beams anchored and grouted in the rock. Separation of the dam from the foundation at some points has already been found by measuring gauge lines spanning from the foundation to the dam. Internal distortions and temperatures are measured by 140 carbon resistor strain gauges (known as telemeters) buried in the concrete.

From the data obtained by the various instruments, all types of movements can be determined and checked. Both vertical and horizontal bending of the arch can be computed independently from data from the vertical clinometer, the change-of-radius meter, and the telemeters. Movements of the central portion of the dam as a body can be obtained directly by the theodolites and vertical clinometers and checked by the telemeters, strain gauges, and change-of-radius meters. Total tensile and compressive strains, independent of bending, can be measured by the strain gauges and telemeters.

How the Telemeter Works

The telemeters are a product of the United States Bureau of Standards and are a relatively recent invention. Each telemeter consists essentially of a stack of carefully prepared, carbon rings supported between two end-pieces of steel. The stack is protected by a collar of steel which does not interfere with the movement of the end pieces. Electrical leads from without the cartridge are connected to the two ends of the carbon stack. When the end pieces are brought closer together, the contact between the carbon rings is improved and an electrical current flows more readily. Having once calibrated a telemeter, it is a simple matter to detect any relative movement of the end pieces by measuring the ease with which an electric current flows through the stack. When a telemter is buried, the end pieces are bonded to the concrete and any internal movement in the concrete affects the distance between them and consequently affects the electrical resistance of the stack. As small a movement as two millionths of an inch per inch of length can be detected with some certainty. In fact, in the experimental dam, the free expansion or contraction due to the change in temperature which occurs in a few minutes has definitely been obtained.

The experimental dam is built with a very small factor of safety. With the reservoir filled, it would be unsafe to make measurements on the downstream face without knowing something of the stresses in the concrete. It is here that the telemeters have an added utility of great importance. For they are wired to a control station above the dam where there is no danger. Enough readings can be made and interpreted in a few minutes times to show with some assurance whether or not the dam is safe. If it is safe, observers can obtain readings of all instruments. If it is not safe, readings of the telemeters can be taken without danger until the very time that the dam bursts. These are the readings which reveal the greatest differences between calculated behavior and actual behavior and are therefore of utmost value.

Tests to Be Fruitful

The reservoir has not been filled as yet, but tests are being made regularly to study the effects of shrinkage, unequal heating, curing of the concrete, and other necessary items. It has been found that each morning when the sun begins to shine on the upstream face of the dam, the central portions begin to move upstream. The cracks between the abutments and the dam on the upstream side begin to close up, the pressure on the upstream toe of the lower portion of the foundation increases, while noticeable bending takes place throughout the dam. In the afternoon, the dam deflects downstream again and returns to its early morning position. The largest upstream movement observed in a single day has been a twentieth of an inch. On account of the movement while the sun is shining on the dam, it is necessary to make the principal observations between midnight and sunrise so that the results represent the equilibrium conditions of the dam.

The concordance between measurements with the various instruments is decidedly satisfactory. Every indication is that no large eccentricity of behavior of the arch will be missed. By pushing the test to the limit and being able to read distortions until the last minute, before failure, there is little question but that the tests will be fruitful.

New Cement Manager

J. E. Jellick, for the last three years district engineer in charge of the Los Angeles office of the Portland Cement Association, has been appointed manager of all the Pacific coast offices. He will make his headquarters at 785 Market Street, San Francisco.

For Detailed Listings, Branch Offices, Etc., See the Buyers' Guide to Leading Supply Sources—Pages 55-56

Engineers Invited to View Concrete Pipe Tests

The California Associated Concrete Pipe Manufacturers hold their mid-summer convention at San Jose on July 10, with a program especially designed for engineers and others who wish an insight into the rapidly growing industry of concrete pipe manufacture.

There are approximately fifteen thousand miles of concrete pipe installed in California alone and more than two thousand miles being manufactured per year to meet the ever expanding fields for standardized concrete pipe. As a feature of the convention the Manufacturers Association will present a series of public tests on irrigation, sewer and culvert pipes, to show the range of uses to which these products are adapted.

Hydrostatic tests will be run on single units and laid sections of concrete pipe to show their resistance to internal pressures when used as conduits for carrying water under pressure heads. The imperviousness and tensil strength of non-reinforced and reinforced concrete as manufactured by various methods will be brought out by the hydrostatic tests.

Crushing Tests Planned

Crushing tests will be run on single sections of both plain and reinforced pipe to show their resistance to external loads. The materials, gradings, proportions, and methods of manufacture will be exhibited for each specimen tested, and score cards will be furnished to all visitors who desire to keep records.

The tests will be held in the yards of the Merritt Company, 1700 South First Street, San Jose, Calif., where a modern manufacturing plant will be in operation so that visitors can view the manufacturing process in all its details, for "machine-made" concrete pipe.

The following is a condensed outline of the tests to be made:

1. *Irrigation Pipe:* Hydrostatic tests on light laid lines of 12-inch concrete pipe showing three types of reinforcing, two types of joints and ten tests on individual sections of pipe.
2. *Sewer Pipe:* Hydrostatic tests on light laid lines of concrete sewer pipe as used in sanitary sewers of Palo Alto and Yuba City, and 22-inch Watsonville pressure sewer outfall. Also crushing test on individual joints of above pipe.
3. *Culvert Pipe:* Crushing tests on four types of plain and reinforced concrete culvert pipe.

McNary Bill Meets Defeat

By a vote of 45 to 39 the McNary farm bill was defeated in the Senate in June after a long and hard battle. Charles L. McNary, Oregon Senator, was the measure's legislative sponsor.

WOOD PIPE

WOOD Pipe for irrigation—water works, sewers, etc., made in sizes from 2 in. to 14 ft. diameter. Made of California Redwood or Douglas Fir. Not affected by acids, salts or alkali. Let our engineers solve your problem.

IRRIGATION MANAGEMENT

DON'T ABANDON CULTIVATION, FELLOW IRRIGATORS

By R. P. LEHR

WRITERS ON agricultural subjects within the past few years have given considerable attention to cultivation in its relation to the conservation of soil moisture. Often, in fact, other equally important aspects of cultivation have not been treated with the fullness which their importances deserves.

If our consideration of cultivation is restricted to so narrow and incomplete a viewpoint, we may be apt to disparage cultivation as a practice simply because it probably does not conserve moisture as effectively as we formerly believed. But, we must scrutinize the complete mission of the cultivator as a crop producer, for, in the final analysis, water is applied to soil for crop production and this is also the aim of other cultural operations. To put the matter briefly, it will always be important and necessary for us to till our soils thoroughly even though it may be demonstrated that cultivation is not an effective moisture saver, insofar as surface mulches are concerned.

There are a wide variety of cultivation methods but the only one which will be discused here is the deep type of cultivation which has been found most effective in thorough aeration of the upper twelve inches of soil, and for breakage of such hard formations as we know by the names of plowpan, plow sole, irrigation harpan, etc. There are, of course, many shallow methods of cultivation such as accomplished by the pegtooth harrow, spring tooth harrow, disc harrow and other shallow cultivators. These will not be treated here, for they are simply methods of surface mulching to save moisture, and are possibly not effective enough to pay the costs, although as weed-control measures they are well worth while.

Seepage Is Necessary

Primarily, thorough breakage of the soil column is important to permit good seepage of irrigation waters. These should not stand upon the surface long enough to drain into the low contours, thereby washing soluble material from adjacent ground and concentrating it in the low spots. Water should not stand upon the surface long enough to destroy the bacterial life in the top twelve inches of soil, and, in some classes of soils and climate, it should not stand in the upper soil long enough to permit baking. If these detrimental effects are to be avoided in irrigation, thorough deep cultivation must be practiced, not only during the season in which weeds are a hindrance to the crop, but even after objectionable weeds have been successfully controlled. The reason for this lies in the fact that cultivation is important as an aerator.

When we enter this subject, we reach the complications of soil chemistry and biological phases which the careful student now concedes to be equally as important as the conservation of moisture. Aeration determines the degree to which chemical reactions in the soil can progress. This is particularly true of our beneficial acids. Chief among these are found carbonic acid and those of the nitrogen group.

We find also that such important constituents as lime, sulphur and iron are essentially affected by aeration. Oxygen plays a very important part in the conversion of all these materials into crop, for they must first be oxidized and dissolved before the plant can utilize them. A piece of glass buried in the soil will be delicately etched by roots which pass along its surface. This etching is accomplished by the acids present, and oxygen is of prime importance in the complicated organic and inorganic processes by which these acids are produced. Our beneficial soil acids are the means of breaking down soil grains into soluble plant food. Without these beneficial acids our soil grain remains an insoluble particle of rock dust. Oxygen plays as important a part in this change as it does in the change of the iron particle into rust which is a soluble oxide of iron.

Soil oxygen introduced by thorough cultivation is also of prime importance to bacteria life in the soil, i. e. it is of value to the general classes of beneficial bacteria. The term "bacteria" is here used to embrace all the lower forms of organic life within the soil, rather than those in particular which are probably low forms of animal life. We know that these forms of life are seriously hindered in development by a lack of oxygen. We also know that other detrimental forms of bacteria develop when oxygen is lacking, providing conditions for their nutrition are favorable.

Soil bacteria are responsible for the production of carbonic acid in the soil. This acid is of prime importance to all crops producing starch or sugar, for from this carbonic acid is obtained the carbon dioxide so useful to the leaf system where it is received in the form of a gas and converted in the plant laboratory into crop. Therefore, we see that thorough deep breakage is necessary in order that these low organisms may have life-giving air because deep breakage allows this valuable gas free access to the surface and to the air from which the leaves remove it.

A soil allowed to "crust" is greatly hindered in ability to "breathe," or replenish its supply of oxygen by means of changes in barometric pressure and temperature during the day and night.

Europe Leads in Study

I do not know why this subject should be more exhaustively investigated by soil chemists in Europe than it has been in America, but this seems to be the case. They seem to be ahead of us in acknowledging and demonstrating these facts. In this country we accept readily what we see at the surface of soil problems but apparently are not particularly interested with the more complex and important reactions upon which successful crop production is largely dependent.

It is conceded by most of our prominent agricultural authorities that cultivation is becoming more important as the science of soil treatment becomes more comprehensive. The corn grower of the central states knows that he can grow a fine crop if he cultivates thoroughly right throughout the season, even

PIPE

Both USED and NEW--At a SAVING to YOU!

WHENEVER and wherever you need pipe of any size or dimension, Pacific can serve you and save you money, too. For general farm and irrigation purposes, Pacific Reconditioned Casing is a real bargain. Absolutely guaranteed. Every length straight and clean with new threads and couplings, each protected from damage in shipping by special steel protectors.

Every length rattle-tested and steam pressure-tested as proof against weakness; then dipped in a special non-tasting hot asphaltum which resists alkali and corrosion. This adds years to its life. Nowhere else in the West, except in the Pacific plant, can used pipe be so thoroughly reconditioned and then sold at such low prices.

after his weeds have been controlled. He may not know that his tillage operations are assisting chemical processes in the land and the various forms of bacteria life that work there but such is the established fact. It is not necessary for him to cultivate to conserve moisture, for in average seasons he has an abundance of it.

The Hopi Indian grows a crop of corn by his intensive methods of cultivation, even where agriculturists sent to him by the government turn away in dismay. He thinks that he cultivates his corn to destroy bugs and devils sent to take away his food. It can hardly be said that the sandy soil holds its moisture better from his cultivation methods. It is a fact, however, that he is unknowingly assisting other agencies upon which the root systems of his crop depend for food.

In analyzing our problems of cultivation, we must not discard our cultivation simply because we may learn definitely that it does not prevent evaporation of irrigation water from the surface soil. It would be equally unjust to condemn the cow if we were to discover, by some exhaustive research, that her milk was not actually beneficial in the cure of tuberculosis, as formerly believed. The value of a cultural process must be weighed from all angles. It would be folly to abandon it on the discovery that it is lacking in one particular.

Irrigation Shortages Predicted on Federal Projects

Water supply conditions on the federal irrigation projects of the West are described in a statement issued through the Bureau of Reclamation as slightly below normal.

With the exception of the state of Colorado, irrigation water to be derived from snow will not be up to normal with deficiencies in run-off probably most marked in the Pacific northwest.

Light irrigation shortages are anticipated for the Milk River project, Montana, the Umatilla project, Oregon, and for the Truckee lands of the Newlands project, Nevada, although in the case of the last named, conditions are more favorable than at the end of April. A serious shortage now appears unavoidable on the Okanogan project, Washington. All other Reclamation projects are at this time assured of an ample supply of irrigation water.

The Colorado River may reach very low stages in late summer, owing to abnormal conditions in the Green River Basin in Wyoming, which may result in a deficient supply for the Imperial Valley of California.

How Beverly Hills Met the Hydrogen Sulphide Problem in Its Domestic Water

By RAY L. DERBY

Sanitary Engineer with the firm of Salisbury, Bradshaw & Taylor, Los Angeles consulting engineers. Mr. Derby has been devoting his attention for more than a year to the special problem discussed in this article.

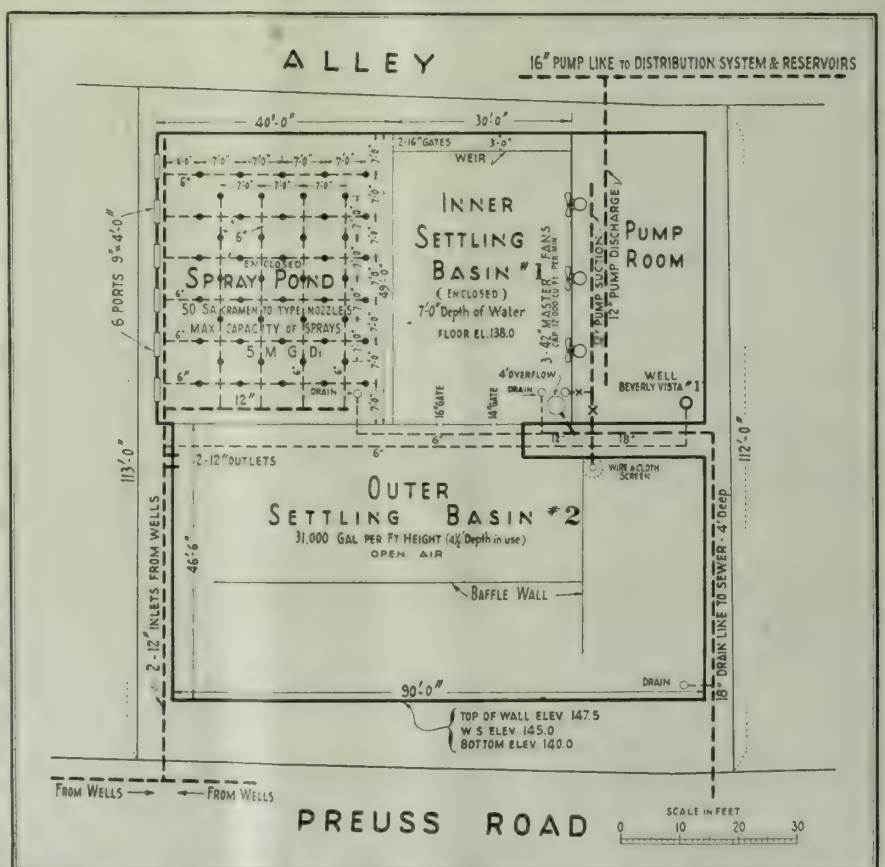
THE HYDROGEN SULPHIDE problem in Beverly Hills, California, has given rise to three distinct problems, viz; the elimination of H2S from the water; the treatment of the H2S in the air given off by the water, and the treatment of tastes and odors due to algae growth aided by the chemical composition of the water. It is the purpose of this article to deal with the first two phases only. The third phase, though closely related to the first two, is outside the scope of the present article.

A brief history and description of the water system of Beverly Hills will first be given so what follows will be more easily understood:

Outline of Situation

The city of Beverly Hills is a strictly residential community, lying about ten miles west of Los Angeles. The residences are all of the high class type, one-third or more of the area being devoted to estates of one-half to ten acres, on which lawns and shrubbery abound. Many residences have swimming pools of 20,000 to 100,000 gallons capacity. The water consumption varies greatly with the seasons, the summer demand being about double that of the winter.

Since the 1920 census, which gave Beverly a population of 674, the growth has been rapid until at the present time it is estimated to be at least 11,000. The water consumption has jumped from a maximum summer demand of 1½ m.g.d. in 1924, to 3 m.g.d. in 1925 and nearly 4 m.g.d. at present, (May 1926).



Diagrammatic layout of Beverly Hills plant for treatment of hydrogen sulphide gas in domestic water supply. The outer basin is the latest unit to be added to the plant.

There are two distinct sources of supply for Beverly Hills:—a small supply comes from two wells known as Franklin Nos. 5 and 9 at the junction of Franklin and Coldwater Canyons. This source contains no H2S, or iron, and is relatively soft and of low total solids. Table 1 tabulates the several sources of supply as to quantity and characteristics.

The main supply is developed in the southern part of the city in what is known as the La Cienega Basin. It is in this basin that H2S is found in the water. The geology of the Basin is interesting: Of the 11 wells put down within a radius of less than one-half mile, no two have shown comparable logs or water. Wells but 600 feet apart have furnished radically different water, such as Beverly Vista No. 1, which is less than 700 feet from the Willows group. (See Table 1).

Yields Differ Widely

Another well drilled but 600 feet from City No. 1 gave no H2S but was highly charged with methane, and was so highly mineralized that it was necessary to abandon it. The total mineral content was 146 gr. per gal., or nearly 2500 ppm.

Prior to January 1924, the only wells in the La Cienega Basin were the Willows group. But little trouble had been encountered up to this time, as the Willows wells were low in

H2S, which was amply taken care of by a small aerator. Aside from the hardness of the water, no complaints were made when the wells were used.

With the beginning of 1924, the city took over the water system and, due to the rapid growth, additional wells were drilled; the first three being the Gold Seal Group. As these all showed H2S from the start, it was decided to build one central plant to aerate all water that might be developed from this basin in the future. This aeration plant was first put in operation in June 1925.

The original plant consisted of the spray pond, weir chamber, settling pond, and pump room. The spray pond contained 30 nozzles of the type developed at the Sacramento Filtration Plant by Prof. C. G. Hyde of the University of California. The nozzles were spaced on 7-foot centers and had a maximum capacity of 3 m.g.d.

the writer is now working, and about which more will be said later.

About a month after the plant was placed in operation, complaints began to come in about tastes and odors in the water, and from sparsely built-up sections calls came in about "black and inky" water. The complaints of tastes and odors were of two classes, and were confined chiefly to different localities at first. One taste (or odor) was of distinctly H2S character and occurred principally near the aeration plant, or in localities not much built up, where the water might tend to "dead end." The other taste was variously described by irate citizens as "musty," "moldy," "old rain barrel," or "old gunny sack" and occurred at first in localities remote from the plant, but soon became general. This latter was caused by algae, but will not be dealt with here.

From the nature of the complaints of H2S, and "black water," it was thought

TABLE 1

Franklin No. 5	16	85	30	0	233	325
Franklin No. 9	16	86	15	0		

From fear that the H2S evolved by the sprays would be objectionable, the entire building was housed over, allowing a 4½-foot space between the maximum water surface and the ceiling. At the end of the building over the sprays were four 4x5 down takes, and in the partition between the settling pond and the pumps were placed three 42-inch fans of 12,000 cubic feet per minute capacity each, discharging into 48-inch stacks to a point 30 feet above ground.

It was hoped that the H2S evolved would be carried up high enough to be sufficiently dissipated, so that no nuisance would be created in the neighborhood, at least at that time when the neighborhood was but sparsely settled. Due to the density of the gas and the trade winds, which are nearly constant in direction, and very strong in summer, the dissipation of the gas into the air was not as thorough as hoped for. This has given rise to a problem upon which

that the aeration was inefficient, so that tests were at once made with the following results:—

	(P.P.M. of H2S)
Water at inlet to plant	8.2
Water under sprays	4.3
Water at outlet to settling pond	3.6
Water in pump room	3.0
Water in pump line 3800' from plant	0.8
Water in pump line 8000' from plant	0.4

From these results, two things are outstanding: viz., that the aeration was inefficient, and that time is a great factor in the elimination of H2S.

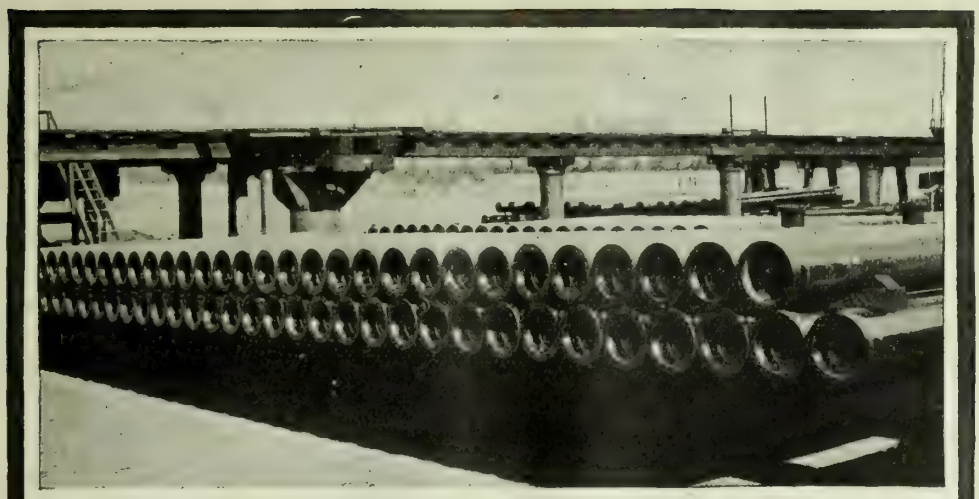
With the low volume, 1½ m.g.d. in 1924, and the wide spacing of nozzles, the sprays did not have sufficient interference properly to break up the water for complete liberation of H2S. To aid in this a positive pressure blower of 450 cubic feet per minute at 5 pounds was installed, and perforated air pipes were placed in the weir chamber.

Tests were made concerning the efficiency of this method, and also of longer retention with results as shown:—

Time	Without Compressed Air	With Compressed Air
Inlet	8.2 p.p.m.	8.2 p.p.m.
Pump	4.1 "	3.9 "
1 hr. retention	2.9 "	1.3 "
2 " "	2.7 "	0.9 "
4 " "	2.2 "	0.2 "
8 " "	1.3 "	0.2 "
24 " "	0.5 "	0.2 "

The blower was decidedly noisy to operate, and because its slight benefit to the water was not compensated by its operation cost, it was decided to discard it and substitute longer retention and better air circulation through sprays. Accordingly, the outer basin was built, giving one hour more retention and additional ports were cut in the wall at the spray end. Three months ago, 20 additional sprays were added, making a total of 50 nozzles on 3½-foot centers.

"What will we do with the gas now that we have taken it from the water?" is the question that is now confronting Beverly Hills. The neighborhood has been complaining about the odors that come from the plant. This photograph shows aeration plant and plainly illustrates the effect of H2S on trees in the foreground.



deLavaud Centrifugal Cast Iron Pipe

—is now ready to ship in sizes from 4″ to 20″

The principal features of deLavaud Centrifugal Pipe are:

1—Lower cost per foot.
2—Greater carrying capacity due to larger inside diameter. Its smooth surface produces less friction.
3—An even greater resistance to corrosion owing to its finer granular structure.
4—Cheaper to install owing to its uniform lead space and self centering bell.
5—It is easier to cut and tap.
6—Its greater strength and uniform section makes it valuable for use for higher pressures.
7—Adaptability to special joints due to its smooth exterior and uniform circumference.
8—It is made to be used with standard fittings and specials.
9—Annealing gives a uniform metal with no casting strains.
10—This method of casting leaves no possibility for sand holes or gas pockets.

Write for special literature covering manufacturing conditions and specifications of deLavaud Centrifugal Pipe.

ITS NOT in the HEAD ITS IN THE PUMP!!!

Mister Dealer

Mister Pump User

Here is news! Interesting news! For both of you.

Smallest Diameter Five Inches — Minimum Capacity Fifty Gallons Per Minute

EACH SIX FOOT UNIT A PUMP IN ITSELF

Satisfaction assured to both the Seller and the Buyer. The Kimball story is complete—read it!

ADAPTABILITY. Large capacity from small well.

LOW PRESSURES. The spacing of the impellers reduces the pressure to less than three pounds at any part.

STRAIGHT WATER COURSE. Water is raised in a straight upward course.

EXTENDABILITY. All extensions made from the top. Each six-foot section a complete pump.

STRAIN DISTRIBUTION. Direct flow allows spacing of impellers evenly throughout the shaft.

WIDER RANGE. Semi-displacement permits a wider range of speed and capacity.

REPAIRS EASILY MADE. All parts interchangeable. Don't return the Kimball to the factory.

GASSY WELLS. Gas and air bubbles are raised with the water — no pockets to collect either.

CAPACITY. Greater from a given size well with unusually slow rotative speeds.

POSITIVE LUBRICATION. Lubricated with soft grease from the inside under high pressure, through hollow shaft.

LONG LIFE. Only the best of materials, combined with skilled engineering practices, go into Kimball Pumps.

Interference of sprays is now excellent and the elimination of H2S from water thoroughly satisfactory. Except when pumping into outer basin while cleaning inner basin, in which case water does not pass through sprays and receives practically no aeration, no trouble is caused from H2S or, "black water."

The black water is, of course, caused by the H2S attacking the iron of the pipe with the formation of iron sulphide, which is easily detached and carried into the system. This is readily corrected by a thorough flushing of the mains in the district in which it occurs.

RAY L. DERBY

Recent tests show that, with five second feet passing through the plant, and but two hours retention, the H2S is reduced from 8.4 p.p.m. at the inlet, to 1.3 p.p.m. at the pump discharge. This amount is below that which can be normally detected by taste and is also about the limit of reliable chemical detection. Many reducing agents present in the water may act upon the solutions used and cause erroneous results.

It is felt, therefore, that as far as the elimination of H2S from water is concerned, this has been accomplished to a satisfactory degree.

From the very first operation of the plant, the odor of H2S has been pronounced in the vicinity. Aside from laboratory tests and studies being carried on, no very definite steps were taken toward the elimination of this nuisance until recently, for the plant was enjoying relative isolation for the first two years. It was possible at times, especially during the rainy season, to get along with the Willows Wells or only one or two of the lesser H2S producers.

The air escaping from the three stacks was analyzed and found to contain 3.9 p.p.m. of H2S. On the basis of 37,500 cubic feet per minute delivered by the three fans, and 24-hour operation, about 170 pounds of H2S is eliminated per day.

Various methods have been considered or tried for the elimination of H2S from the air as follows:—

1. *Ozone.* This was tried out on both the air and water and, while successful, would be excessively high in installation and operation costs.

2. *Chlorine.* The Henderson-Haggard process of odor elimination by use of Chlorine was considered, and while their representative was willing to guarantee satisfactory results with this method, it was not given a trial except possibly as a last resort. Since two parts of Cl combine with one of H2S it will require at least 350 pounds of Cl per day or, at 12 cents per pound, an operation charge of $42 per day. Hydrochloric acid may also be formed, which will be objectionable.

3. *Burning.* Burning has been tried out and found to be successful to a certain point. Two objections to this method are that successful burning requires less draft than is believed necessary for satisfactory aeration of water, and close regulation of combustion needed. If complete combustion is obtained, the H2S is converted to SO2, which, though perhaps less objectionable than the former to the sense of smell, is much more destructive to property.

Burning Presents Difficulties

The advantages are that the heated air will rise higher and probably be dissipated more. If properly regulated, the SO2 that is formed will combine with H2S still present, to form free sulfur and water, neither of which are objectionable. The cost of burning will be about five to seven dollars per day.

4. *Sulfur Dioxide.* Experiments are being carried on at present with the use of SO2. Crude sulfur is burned between the sprays and the fans. The period of contact is about one minute which does not appear to be entirely sufficient for complete reaction. At the top of the stacks, the odors of H2S and SO2 are both distinguishable. Some distance from the plant an odor like neither of these two gases is noticed, but of a rather musty character. This is so faint, however, that it is not highly objectionable, as compared to H2S alone.

Some difficulty is being experienced with getting a thorough mixing of the two gases before leaving the stacks. It is believed, however, that this will shortly be overcome. This method appears to be one of the cheapest and simplest so far considered. About 160 to 170

For Detailed Listings, Branch Offices, Etc., See the Buyers' Guide to Leading Supply Sources—Pages 55-56

pounds of sulfur are used per day, at a cost of $30 per ton. What effect the SO2 fumes will have on the metal within the building remains to be determined. Provided a complete reaction occurs, their effect should be nil.

ABSORPTION MAY BE USED

5. *Absorption.* Various alkalies such as soda ash, lime, caustic soda,etc., will readily react with H2S. By passing the gas through an absorption tower with one of these alkalies present in solution, the H2S will be taken in solution and eliminated from the air. This method has not as yet been tried, as it was thought best to try more simplified methods first. In event that others fail, it will undoubtedly be used as a last resort.

The writer would be glad to hear from anyone having had experience in any similar problem, and will welcome any suggestions.

The various tests and experiments on both the water and the air were carried on under the direction of the writer in collaboration with F. S. Moon, Jr., of the Western Precipitation Company.

How the Big Dam Was Built

(*Continued from Page 15*)

"Consider also that an average height-limit Los Angeles office building, with its twelve or thirteen stories, will often include in its construction about 5000 cubic yards of concrete. Compare this with the Exchequer dam, in which that amount of concrete was sometimes poured in two days' time, and where the total pourings for the structure amounted to 374,000 cubic yards. The concrete in the dam, on this basis, would provide material for a city of seventy-five average sized office buildings.

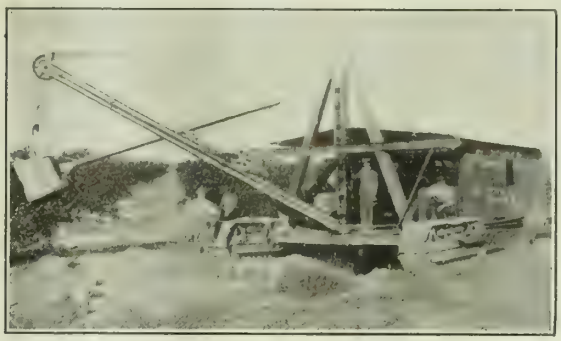
"Our best records in pouring this concrete will, I think, rank with any yet made on any comparable job. In the first twelve months after signing the contract, we poured 225,000 cubic yards. We made a maximum monthly total of 50,000 cubic yards, and our highest daily record was 2000 cubic yards. In reporting these marks through a national magazine, we invited a comparison of records, and only two efforts were made to challenge our championship in point of daily and monthly maximum."

In concluding his remarks, Mr. Bent paid high tribute to the ability and efficiency of the engineers of the district—R. V. Meikle, A. J. Wiley and Ross White—and spoke in cordial appreciation of the work of his own lieutenants, the men who have stayed on the job and seen it through, especially L. T. Grider, general superintendent and M. H. Slocum, job superintendent.

For Cleanout -- Maintenance -- New Ditches

There's a Bay City for Every Job

BAY CITY Land Dredges span the ditch, can dig any desired slope, and dump waste on both banks. BAY CITIES leave clean, wide berms, and can work up or down streams. One trip over the ditch is enough. The Shovel Type Dipper handles hard material in which other types of buckets cannot make a good showing.



At left—One yard BAY CITY Dredge digging and cleaning ditches in Florida Citrus Groves.

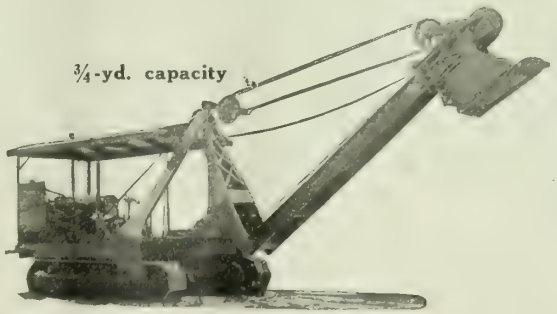
BAY CITY Land Dipper Dredges are built to fit the job. Walking, Crawler, Track or Floating mounting. Easily dismantled, transported and assembled. Capacities ½ to 1½ cubic yards. Oil engine or electric operation.

FOR SMALLER DITCHES — OR PIPE LINE TRENCHES

The BAY CITY 16-B convertible Excavator will handle a wide range of work. Operates Dragline, Trench Shovel, Clamshell or Skimmer. All steel. Shipped assembled. Digs any width or depth up to 20 feet.

STEEL CONSTRUCTION

¾-yd. capacity



FULL CRAWLER MOUNTING

or—Model 4 Excavator

BAY CITY Model 4 is a small low-priced convertible, one-man operated Excavator. Fills the gap between hand labor and high priced equipment. Capacity 20 to 40 cubic yards per hour. Gasoline or electric power. A Real Digger economically designed for the small job. Also operates shovel, and clamshell.

TRADE NOTES *of the* MONTH

Water-Works and Irrigation Men Welcome Pipe Clamp

The Philbrook Spring Pipe Clamp Company, Los Angeles, is fortunate in having developed a product which fills a genuine need shared equally by the irrigation and water works industries, if the continued cordial reception which is being accorded the spring pipe clamp of that company's manufacture may be made the basis for judgment. Large companies in all parts of the west are adopting the Philbrook clamp after investigating its usefulness. Among California users of the product are such representative companies as the California-Oregon Power Company, San Francisco San Joaquin Light and Power Company, Fresno; City of Riverside, City of Redlands, City of Los Angeles; North Corona Development Company, Norco; Lake Hemet Land & Water Company, Hemet; Lindsay-Strathmore Irrigation District, and other power, land and irrigation projects.

The particular advantage to which the Philbrook company ascribes the increasing popularity of its clamp is its patented feature which permits of its adjustment around the pipe practically instantaneously, without handling two or more detached parts of the device, as is usually necessary in such appliances. The Philbrook clamp is a unit, which is clamped quickly round the pipe and tightened in an instant. It differs from other types of clamps also in that it is flexible, conforms to the contour of the pipe instead of lying tangent to its surface, and provides the highest pressure where it is neeeded, at the point of the leak. It is made in all sizes from two to twenty-four inches in diameter.

Armco Celebrates Anniversary of Corrugated Culvert

This year the 30th anniversary of the invention of the corrugated culvert is being celebrated by the Armco Culvert & Flume Manufacturers Association. The celebration was initiated by an exchange of telegrams between Walter H. O'Neall, president of the Association, and George M. Verity, president of the American Rolling Mill Company, in which Mr. Verity said:: "It is a significant fact that though the corrugated culvert is thirty years old Watson's original design has remained unchanged and is daily acquiring a host of new friends."

A feature of the celebration is the display in the Association's research laboratory at Middletown, Ohio, of the first corrugated culvert ever made. This culvert was manufactured by the inventor, James H. Watson, and placed early in 1896 under a public highway near Crawfordsville, Indiana, from which location it was recently removed for exhibition purposes. It is one of many similar culverts still in service near Crawfordsville.

Increased Water Activity Reported by Pomona Co.

Indicating extensive development of new water supplies by various irrigation companies, the Pomona Manufacturing Company, of Pomona (Calif.), has reported the recent installation of several large plants.

The Del Monte Irrigation Company has just begun operation of a new plant, producing 630 gallons of water per minute at a 200 foot lift with a 44-horsepower motor. This is one of the largest installations near Pomona.

Another large installation was completed for the San Dimas Water Company at San Dimas, California, producing 540 gallons per minute with a lift of 340 feet, using 70 horsepower motor.

Another large insstallation was completed for the Oak Water Company at Charter Oak, California. This plant produces 450 gallons per minute from 400 feet.

Other interesting California installations completed by the Pomona firm include those for:

The Italian Vineyard Company at Guasti, 1350 gallons per minute; the Monte Vista Irrigation Company at Ontario, 1150 gallons per minute; the Tustin Water Works at Tustin, 630 gallons per minute; the Cutler-Lobinger Packing Company at Ontario, 90 miner's inches from a lift of 180 feet; the City Water Company at Visalia, 450 gallons per minute; and a very fine plant for A. Carricaburu at Riverside, 630 gallons per minute.

Sterling Pump Chief Reveals Results of Recent Test

Results of a recent test by the San Joaquin Light & Power Company, Fresno, have been made by the Sterling Pump Works, the manufacturers of the pump which was used in the experiment. A statement by J. E. Lundy, general manager of the Sterling works, say:

"We have been greatly gratified to learn of the results of this interesting test. A Sterling pump in the Bakersfield territory delivered 1100 gallons per minute; pump head 65 feet; horsepower input to motor 28.95; overall plant efficiency 63 per cent. This represents a cost per acre-foot of .92188; cost per 24 hours of operation, $4.51."

Mr. Lundy declares that much of the credit for this high type of performance may be given to the experimental department of the Sterling organization, which devotes much time and expense to developing pumps of high efficiency.

He incidentally points out that production and sales records of the company are being broken by the current demand for pumps, and that the present season is the busiest one in its history. Two shifts of men are kept busy turning out pumps to fill orders coming in from all parts of the west, Mexico and a number of far eastern points.

Visits Armstrong Factory at Waterloo, Iowa

Harry C. Kaufman, president of the Kaufman Company, Los Angeles, distributors of Armstrong drilling machinery, has recently returned from a sixty-day trip to the Armstrong factory at Waterloo, Iowa, and other points in the midwest and northwest, making a study of well-drilling conditions in the various irrigated sections through which he passed.

Mr. Kaufman reports that the Armstrong organization is enthusiastic over both the current and prospective business in the Pacific Coast territory, and that there is a growing demand visible throughout the irrigation country for equipment of this manufacture. One of the reasons for the keen interest in Armstrong equipment among well-drill-

ers, according to Mr. Kaufman, is its exclusive patented feature which permits of the use of a wire-line in the derrick instead of a manila line.

Bottom-Dump Pull-Shovel Introduced to Trade

The Northwest Engineering Company have recently added a new trench pull shovel to their line. This machine is in general principle similar to the standard Northwest Pull-Shovel first put on the market in 1925, but is different, in that it is equipped with a bottom-dump bucket instead of the scoop type used on the other model.

The bucket is hinged back of the teeth. This allows the bottom to drop out when a bolt is pulled by the cord in the operator's hand. When the bucket is returned to the ditch in the process of digging it automatically closes on striking the bottom of the cut and the bolt holds it in place.

Buckets are supplied in two sizes for each of the Northwest models; 33 inches and 39 inches wide on the Model 105, and 42 inches and 48 inches on the Model 104.

This machine is, like all Northwests, equipped with the "feathertouch" clutch control, and the exclusive Northwest patented steering device which allows full traction while turning as well as going straight ahead.

Western Product Enters Into World-Wide Trade

A western product which is rapidly expanding its market to embrace the world-wide field is "Laykold" the bituminous material manufactured by the Crown Bitumens Corporation of San Francisco for canal lining, street paving, etc. Laykold is now being exported to Australia, New Zealand, the Hawaiin Islands, Canada, Ecuador, various other points in South America, and Johannesburg, South Africa. Experiments in varied uses of the product are being carried on at the present time in points as remote as Germiston, South Africa and Wellington, New Zealand.

Sells Big Order in Texas

L. C. Fay, a sales engineer for the Byron-Jackson Pump Manufacturing Company, has just returned from Fort Hancock, Texas, where he has been for the past month. The trip took him to the mid-continent section and throughout Texas in the interests of his company. It resulted in the signing of contracts for the sale of forty deep-well turbines to the Hudspeth County Conservation and Reclamation District Number One, a Texas district which is undertaking some very active developments.

The Vital Link

between the two Main Tunnels of the Hetch Hetchy Water Project, is the "South Fork Crossing," an exposed pipe aqueduct. It is coated inside and outside with

Biturine

"The corrosion preventive" with a 20-year record

The vital importance of this pipe line naturally called for a Corrosion Preventive of undisputed dependability.

Our Modern Handbook "Pipe Protection" is yours for the asking. Write for it. Contains comprehensive specifications.

IRRIGATION FINANCE

How Can the Government Promote the Prosperity of the Country

By C. E. GRUNSKY*

WHEN the price of wheat was fixed during the war, the indirect effect was to raise the market value of farming land. The promoters of the scheme to stimulate the production of food may not have had this prospective effect in mind, but the fact is that much mischief has resulted, from which certain sections of the country have not yet fully recovered.

So, too, when under the provisions of the United States Reclamation Act passed in 1902, the farmer home builder was covertly offered a bonus in the shape of a waiver of the interest charge on funds advanced by the Government for the construction of irrigation works, an attendant result, though hardly anticipated by the framers of the measure, was to add an undeserved increment to land values.

The settler on the irrigated farm thus indirectly received a bonus. He may not have been aware of this circumstance, but the bonus was none the less real, and was sooner or later apparent in the sales value of the irrigated tract. Not only this, but in some cases even the possibility that the government would be lenient and would not demand full return of operating costs, was capitalized.

It is probably safe to say that if the landowners in Government reclamation projects had financed these projects themselves the cost per acre of providing the irrigation works would have been nearly doubled. The 40 to 50 per cent of the cost, which the no-interest provision saved the landowner, is the subsidy which went to the first comer or original owner.

But in the case of every such subsidy or bonus accruing to the farmer, the advantage, if fully realized, stops with the first owner. It cannot be passed on indefinitely, because the capital value, which an assured income, for example,

C. E. GRUNSKY

would create, will never intentionally be passed on as a bonus to a subsequent owner. It follows, therefore, that all schemes to aid the farmer by fixing prices or by guaranteeing the marketing of farm products must fail. It will in such cases be but a few years before the farming business, as the result of unnatural stimulation, will be as badly off as it would have been without the aid of a bonus.

After the foreign market fails to take at a fair price the surplus production of a big country such as ours there is only one way to keep it continuously prosperous. The balance between production and consumption must be studied and carefully preserved. A relatively large group of consumers at home must be created and maintained.

Public works on a large scale, buildings, roads, canals, harbors, public parks, museums, sea coast and mountain places of recreation, schools and other educational institutions should be fostered and endowments encouraged, libraries, art galleries, operas and theatres, and means of inter-communication should be provided far beyond this country's past or present program, preparations for defense, on land, at sea and in the air, should be made without stint as to cost, because the soldier and sailor is for the time being removed from the producing class and made a consumer. This during any period of over production can only make for prosperity, because funds expended for such purposes go into circulation at home and help to swell and stabilize the volume of the country's business. Research work on a grand scale,—social, economic and particularly scientific, should be undertaken, and, furthermore, the middleman should not be run entirely out of business.

A declaration of such a principle, making as it must for relatively high, not relatively low taxation, may not be popular, but when the taxation is equitable and the burden does not fall disproportionately on any class, ability to pay taxes being taken into account, and when the country is assured that there is fair efficiency in government administration—that every dollar expended will produce a dollar's worth of result—then, perhaps acceptance of such a program could be hoped for. It would assure general and lasting prosperity which occasional financial panics and the like could not seriously disturb and in which the farmer would have his proportionate share.

If, however, despite the transient nature of aid to the farmer, he is to be assisted in making his crops profitable,

*NOTE—Mr. Grunsky's interesting comments on the farm problem and some of the possible means of promoting agricultural prosperity will be read with interest because of the prominent position which the author holds in the engineering profession. Possibly not every reader will agree with his conclusions. The editor ventures to make some comment upon his thesis on the editorial page of this issue.—EDITOR.

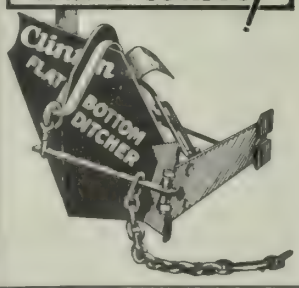
LAYKOLD
EMULSIFIED ASPHALT

THE completion of the Exchequer Dam is another monument to the progressive spirit of Western Irrigation Engineers. Laykold is also a western product and is progressing with Irrigation Engineering. Perfect asphaltic concrete ditch linings are now constructed with this handy product without the use of heat or expensive equipment. When used as a paint to prevent water losses, the results are more than satisfactory.

Crown Bitumens Corporation
315 Montgomery Street,
San Francisco, California

Make Your Ditch a Natural Water Course



Here are— 5 Advantages:

you'll appreciate in this tool:

1. It builds a ditch which carries more water than a "V" ditch, depth and fall being equal.
2. The "off" horse walks on the flat ditch bottom instead of on the slope.
3. Silt fills this type of ditch more slowly and there is less overflow.
4. Erosion is minimized in the flat bottom ditch.
5. It can be cleaned out with greater ease for it keeps its shape.

the extended aid should not be of a character that will encourage his activities as a speculator but rather in such form that it will expedite the movement of the crop to the great centers of distribution.

The simplest method of accomplishing this will probably be found to be by reducing the cost to the producer of transporting the farm products to a market. This can readily be accomplished by granting a rebate payable by the Government on rail and water transportation charges. Such a rebate should be proportional to the freight bills and should be so fixed as to assure movement of the crops; but in no event at more than some specified limit such as one-third or one-half. A single scale of rebates should apply to the whole country with a possible departure from this rate only in case of shipments to foreign countries. For economic reasons it is of prime importance that a fair exportable surplus be marketed abroad. This will aid in maintaining a favorable balance of trade, as well as in maintaining farm activities.

Not a Permanent Cure

No such freight rebate system nor any other form of bonus to the farmer will keep him permanently above water. It will, however, contribute to general prosperity. It will help temporarily the remote agricultural and horticultural sections of the country.

It will be equivalent to giving a bonus to the present owners of farming lands —varying according to location and character of the crops. It will indirectly be of some permanent benefit to the farmer along with the advantages that it will bring to transportation lines and to every other type of business in the country.

It will benefit the farmer who sells at home in the full measure that it benefits the farmer who sells his product to a remote market, because the reduction of freight rates will immediately add value to the farms' output regardless of whether it is shipped or consumed near home. However, as already stated, it will not effect a permanent cure of the farmer's troubles. He will, thereafter, as in the past, have to contend with all the factors that have heretofore worried him and will find that, at intervals of about 20 years,† he will be hard hit by general business depressions unless, indeed, such a program of artificially swelling the consumer class as above indicated be made the policy of the nation. The relatively high taxes inherent in such a policy need not be

†Note: = 1817, 1837, 1857, 1893 to 1898.

feared. They will be collected only from those who are able to pay and who, in their turn, will share in the engendered general prosperity.

It will no doubt be suggested by those who are timid in such matters, that funds expended for an army and a navy, or for monuments and the like, are wasted, but would be conserved if expended in the production of some marketable output.

The answer is that even the funds thus expended go into circulation. The battleship that costs $10,000,000 provides the opportunity of taking this sum from those who have a surplus and putting it into circulation—through the laboring man and thereafter it keeps on moving. For each million thereof expended in some locality, it is probably safe to say, some $12,000,000 worth of business will result in the following 12 months. Even if it be argued that the first expenditure might have been for something more useful than the creation of the battleship, this criticism will not apply to the repeated transfer of the expended sums among the trades people and business men generally. The released million will escape from the local community but slowly, if at all. It will have its effect upon local business and local prosperity much longer than the twelve year period here used for the purpose of illustration.

Similarly, if aid be now extended to the farmer, even though it merely result in giving the present landowners a bonus, the transient stimulant will get many a crop into market which would otherwise not be grown or would be allowed to rot in or on the ground. And wherever this is the case the local community will benefit in business many times the value of the marketed crop, even as it does when it holds in its population an army of professors, or research men or even plain ordinary soldiers.

Philadelphia Exposition Includes Irrigation Exhibit

A model of a 40-acre irrigated farm, showing water running in the canal, laterals and farm ditches, with farmhouse, barns and other outbuildings in minature and with various plots of ground in different irrigated crops, is a feature of the Sesquicentennial Exposition being held in Philadeplhia. The model farm is a part of an exhibit showing the activities of the Department of the Interior. In addition to this feature, irrigation is represented in the government's display by colored photograhps of many representative scenes on the federal irrigation projects, such as famous dams built under government direction.

You *Name the* Load
We *Make the* Pipe!

SINCE concrete pipe (as made by Bent) came into its own, engineers question no longer its striking advantages for a great variety of uses. *But*—a concrete pipe installation is either a mediocre or an eminently superior job of work, depending upon who fulfilled the contract.

Many trade names have become hall-marks of tradition, that serve as an unerring guide to discriminating buyers. Today the name "BENT" on a joint of Concrete Pipe marks it as a strictly finely made product. The same care and skill is exercised in its manufacture, and in the laying of the line, as though every future contract depended on *that* job meeting the fullest requirements of specifications—*and more.*

Let us give you a "concrete" demonstration of what we mean by "Bent" Service.

WHO'S *WHO* AND WHO'S *WHERE*

IN THE WORLD OF HYDRAULICS

Personal Notes and Impersonal Observations About Men You Know

A. L. Hobson, former director of the Palo Verde (Calif.) Irrigation District has resigned his position to take effect immediately. Mr. Hobson's reasons for his resignation were not given in dispatches to the press.

Louis Borneo, president of the Republic of Haiti, who was an official visitor in the United States during June, expressed the keen interest in irrigation and reclamations problems which is felt in his country when he made a feature of his visit a conference with Secretary Work and Commissioner Mead on the work of the American government in reclamation.

Bernable Flores, who for the past five and one-half years has been the chief clerk of the Imperial Irrigation District (Calif.) with offices in Mexicali, California, recently announced that he had resigned his position to take effect immediately. Mr. Flores served for six years as secretary of the El Paso Water Users' Association (Tex.) previous to his going to California.

James E. Baker, of Los Angeles, California, has been selected by the Baldwin Park (Calif.), County Water Board as engineer to have charge of the installation of a water plant in the recently organized district. Mr. Baker was engineer for the Board of Public Utilities of Los Angeles for a number of years previous to his appointment to Baldwin Park.

Governor Hannett, of New Mexico, has appointed a conference committee to confer with representatives of Arizona with reference to division of water of the Gila River. Charles Fuller and L. P. McHaffley of Lordsburg, (N. M.), James Harper of Redrock, (N. M.) and J. B. Beavers and H. G. Alberts of Duncan (Ariz.), are the men that have been appointed on this committee. An agreement between the states is deemed advisable, it is said, in view of the plans to dam the Gila and San Francisco rivers at New Mexican points for the benefit of irrigated farms that lie in Arizona.

A. E. HITCHNER

With the resignation of K. E. Van Kuran, former head of the Westinghouse Electric and Manufacturing Company's activities in the Pacific southwest, comes the announcement that A. E. Hitchner will succeed him. Mr. Hitchner obtained his degree in electrical engineering from Rutgers College in 1904, and he entered the apprentice course for college graduates at the Baldwin Locomotive Works in Philadelphia. After two years training there he was employed by the Link Belt Company, remaining until 1906. After a year's mining operations with the Kaolin mines in Florida, he joined the forces of the Westinghouse Company, and was assigned to general industrial sales work in the Philadelphia office. In 1912 he was placed in charge of anthracite mining sales for the company. From 1919 until his present transfer, he was assistant manager of the industrial department. Mr. Van Kuran, after a long and successful experience as a Westinghouse executive, has resigned to become connected with corporate interests in Los Angeles.

The report of Resident Engineer Harry Barnes, the San Joaquin River Water Storage district (Calif.) to the valuation committee of the district's board of directors will be made and discussed between July 15 and July 30. It is hoped by officials of the district that a solution may be found, based on this report, for the many storage problems facing them at the present time.

Mayor C. E. B. Oldham and Commissioner C. S. Halverson, of Bremerton, Washington, recently made a visit to the Zimmerman ranch near Bremerton on an inspection tour. The city of Bremerton is seriously considering the purchase of the Zimmerman ranch to protect its watershed and to prevent the pollution of the domestic supply of wa-

---

C. C. Teague, president of the California Walnut Growers Association, recently visited Oxnard, California, to attend a meeting sponsored by the Oxnard Chamber of Commerce. He discussed the question of water supply, especially as affecting land owners of the Oxnard district. "We always believed that we had all the water we needed," he said, "but the last six or seven short years have dispelled this view considerably. Dry farming is now considered hazardous, and water for irrigation is absolutely needed."

Dr. Elwood Mead, Commissioner of Reclamation, is in the West on an extended tour of federal reclamation projects. He left Washington June 17, and will return July 21, in the meantime dividing a very full month between various duties connected with the business of reclamation. He appeared late in June on the program of the American Society of Agricultural Engineers meeting at Lake Tahoe, and will visit a number of northwestern projects during July. He will be accompanied by Maurice G. Ricker, photographer, who will make a record of activities on the projects in still and motion-picture films. The Orland Project (Calif.), the Okanogan project (Wash.), and the Yakima project in the same state will be included on the itinerary.

The Story of Exchequer

(*Continued from Page 13*)

obtained from a bar in the Merced River 18 miles below the dam. By careful grading and the use of cobbles in the concrete mix, mass concrete in the dam and spillways averaged only 0.822 barrels of cement to the yard, which includes the cement used for grouting and for the richer mix used in the faces of the dam.

Test cylinders six inches by nine inches showed a strength of 1600 pounds per square inch in twenty-eight days, while cylinders eight inches by twelve inches gave a strength one and one-fourth times as great. The average mass concrete batch was seven sacks of cement, 24.7 cubic feet of sand, 15.7 cubic feet of fine gravel, ¼ inch to 1 inch, 17.3 cubic feet of coarse gravel 1 inch to 2½ inches and 34.8 cubic feet of cobbles 2½ inches to 10 inches; and produced 62 cubic feet of concrete.

Cobbles were not used in bridge pier concrete, which averaged 1.28 barrels of cement per yard, and tested 2500 pounds per square inch; or in tunnel lining which averaged 1.16 barrels of cement per yard and tested 1800 pounds per square inch.

Bids for the construction of the dam, power house and railroad were received by the district May 31, 1924, but due to delay in financing, actual work was not started by the contractors until September, the contract having been signed in August. The total construction time required to build the project and put it in operation was twenty-one months. The total expenditures on the Exchequer Project amounted to $10,800,000, of which approximately $10,000,000 was spent on construction work. The relocation of the Yosemite Valley Railroad cost more than the Exchequer Dam and Power House combined.

A contract between the District and the San Joaquin Light and Power Corporation provides for the sale of the total output from the power plant over a period of twenty years, the District having the option of renewing the contract for another twenty-year period. The average net income from the sale of power is estimated at $470,000 yearly. This co-operation on the part of the power company may be said to have made the building of the project possible at this time.

Storage water to insure a full irrigation supply is essential to the development of the Merced Irrigation District. While irrigation near Merced dates back to 1883, only 40,000 acres were irrigated in 1919 at the time the District was organized. This year 102,698 acres are being irrigated by gravity and 13,500 acres by pumping.

DIGGING—CLEANING CANALS

AT LOW COST

THE NEW RUTH WITH ITS CONTINUOUS FLOW OF DIRT will dig or clean canals and trenches at a minimum cost per cubic yard or lineal foot heretofore considered impossible. The Ruth cuts continuous, even banks and smooth bottoms. Working successfully in marshy or dry ground, or canals full of water. The Ruth positively cleans the canal of all muck, sand, small willows, tules and water grasses.

Send for Bulletin No. 8—it illustrates the New Ruth Dredger; type and size of canals it will dig or clean; gives specifications, operating costs and maximum capacities.

LEGAL *and* JUDICIAL

A DEPARTMENT CONDUCTED BY HANKINS & HANKINS

Defective Applications Must be Heard

Division of Water Rights is required to hear applications although they may be defective in form.

An application was made to the Division of Water Rights of the State of California for a permit to appropriate water for municipal uses. The Division considered the form of the application to be too uncertain and refused to hear the matter. The plaintiff brings an action in mandamus requiring the Division to proceed to hear and act upon plaintiff's application. The trial court granted the writ and an appeal is taken to the Appellate Court and by that court determined in the action of Rich vs. W. F. McClure, etc. et al, 50 Cal. App. Dec. 311 (May 29, 1926).

The appellants claimed that the application was defective in that it did not set forth the intended place of use, the method of transportation or a sufficient map showing the details of the plan.

The Appellate Court states that the cities named in the application being incorporated cities, the courts will take judicial notice of the boundaries of such cities and therefore the place of intended use is sufficiently set forth. It further stated that under the liberal provisions of section 1a of the Water Commission Act a hearing may be held and a permit granted even though the application therefor be defective. Also the application may be granted in part and denied in part.

Appellants urge that plaintiff was not entitled to a writ of mandate because he had a plain, speedy and adequate remedy under the provisions of section 1b of the Act by a hearing in the Superior Court. The Appellate Court points out, however, that this applies only after a hearing has been had and a permit either granted or denied and not where a hearing has been refused.

Prescriptive Rights and Irrigation Districts

A prescriptive right to water may be acquired against an irrigation district.

In a contest between water users of Big Rock Creek in Los Angeles County, California, it was contended that a private water user could not obtain a water right by prescription as against the Big Rock Irrigation District.

This district had been formed under the so called "Wright Act" and for a number of years had used the water of the creek for the lands of the District. Disaster overtook the territory by reason of draught and the district did not function from 1900 to 1914. In the meantime private persons had appropriated all the water. The Big Rock Mutual Water Co. is the successor in interest of the water rights of the District.

In the case of Big Rock Mutual Water Co. vs. Valyermo Ranch Company, 50 Cal. App. Dec. 346 (June 2, 1926) the Appellate Court held: " . . . there can be no question that where public lands have been devoted to a public use, persons cannot obtain title thereto by prescription founded on an adverse occupancy. This principle is indisputable and is not here disputed. It has no application, however, to the instant case. The title or interest that one may acquire in the waters of a stream is entirely different to that which may be acquired in land. Running water, so long as it continues to flow in its natural course, is not and cannot be the subject of a private ownership. A right may be acquired to its use, but this right carries with it no specific property in the corpus of the water itself . . . This interest is dependent upon user and it may be lost when the owner ceases to make avail of the same. . . . This rule has been applied against a public service corporation and there is no reason in principle why it should not equally apply against an irrigation district."

Appropriation of Underground Waters

Waters of an underground flowing stream are as available to appropriation as waters of surface streams.

In the case of Pima Farms Co. v. Proctor, 245 Pac. 369, (April 19, 1926) the Supreme Court of Arizona sets forth the rules governing the appropriation of underground waters. It was conceded in the case that the body of water in controversy was a known independent subterranean stream.

The Supreme Court states: "It is, and has ever been, the policy of this State to make the largest possible use of the comparatively limited quanity of water within its boundaries. In order to do that, it is obvious that some other rule than the riparian doctrine should be the standard adopted. Accordingly, the territory at an early date, and the state upon its organization, abrogated the common law rule of riparian rights as unsuitable to our conditions, and, in accord with most of the western arid states, adopted the doctrine of prior appropriation. Under this doctrine the waters of an underground flowing stream are equally as available to appropriation by the owners or possessors of arable or irrigable lands as the waters of a surface stream, and the appropriation is goverened by the same principles of law."

A further point of extreme interest is made by the Supreme Court where it holds that an appropriator's method of diversion is also entitled to the protection of the court. On this point the Court states: "It is true the means of appropriation are a secondary consideration, and may be changed by the appropriator from time to time if no injury results to others, or may be changed by direction of the courts in proper cases to enlarge the use of the waters of the stream; but the means are not inconsequential because without them the water right would be unavailable and worthless . . . In other words, the appropriator does get something more than a water right; he gets an easement in the bed of the stream and the underflow to support and carry his water so that it may be used and enjoyed, and while he does not appropriate or apply to beneficial use, as that term is understood, the underflow, and while such underflow may be appropriated, those who appropriate it must adopt means to preserve to the prior appropriator his rights without injury to him.

In quoting the case of Salt Lake v. Gardner, 114 Pac. 147 the Court adopts the language of that court as its views of the law, as follows: "Counsel for respondents, however, insist that the prior appropriator acquires no right in his means of diversion, but obtains a prior right only to use the quantity of water appropriated and applied to a beneficial use by him. We cannot yield assent to this view. We think the original taker or appropriator from a stream or body of water also acquires the right to continue to use his method or means of diverting which he has installed."

The Court also disinguishes the case of Schodde v. Twin Falls etc. 161 Fed. 43 wherein it was held that an appropriator of water, diverted by water wheels, was not entitled to claim the right to the continued use of the entire stream to run his wheels, where such additional water was claimed by other appropriators.

Damages from Water Lack, or Poor Husbandry?

Whether damages to an orchard were caused by lack of water or poor farmer is a question of fact to be determined by a trial court.

In the case of Hill et al v. Selah & Moxee Irrigation District, 245 Pac. Rep. 752 (Wash.) (May 5, 1926), the plaintiffs bring a suit against the irrigation district for damages for an alleged breach of a contract to supply them with water for irrigation purposes. The plaintiffs were the owners of 51 acres of land upon which they were entitled to water during the irrigation season, which, by the contract, was fixed as beginning April 1st and ending November 1st. On January 23, 1923, plaintiffs wrote the district notifying it that they were setting out considerable nursery stock and would need water early in the spring. The planting began on March 29th and was finished on April 5th. Water was turned into the ditch at the intake some two miles above plaintiff's property on April 2nd, but did not rise to sufficient height for plaintiffs to get water until approximately April 13.

Plaintiffs claim the damage to the orchard was through lack of water. The district claimed that the damage was not due to lack of water but due to the failure on the part of plaintiffs to exercise good husbandry, in packing, in caring for the grafts, in preparing the soil, and in planting and cultivating.

The trial court found "That the loss sustained by plaintiffs was not due to the lack of irrigation water." The Supreme Court of Washington held that the evidence being

conflicting, the judgment of the trial court would not be disturbed.

The Supreme Court further stated: "We are invited by the respondent district to construe the contract as not requiring the furnishing of water prior to the opening of the irrigation season where the water is desired for a specific purpose, without definite notice having been given . . . it seems best to us to leave the construction of the contract until that question is more nearly directly involved in the determination of a controversy."

Abandonment of Water Right

An intent to abandon a water right must be clearly shown.

In the case of St. Onge v. Blakely, et al., 245 Pac. 532, (March 19, 1926) the Supreme Court of Montana sets out the rule of law as to the abandonment of a water right. The question arose over a suit to determine conflicting water rights where a claim is made that a right had been lost through abandonment.

The Supreme Court says: "It is contended that the Suprenant and Marceau right was abandoned and lost by non-use between 1882 and 1896 . . . but the right was fully perfected prior to 1882 and thereupon became a property right of which the owner could only be divested in some legal manner. He could, thereafter, use the water or not, as he saw fit, or he could abandon the right, but abandonment is a voluntary act involving a concurrence of act and intent—the relinquishment of possession and the intent not to resume it for a beneficial use—neither alone is sufficient to bring about the abandonment of the right. Mere lapse of time, even in excess of the period prescribed in the Statute of Limitations, will not alone establish the abandonment of a water right or work a forfeiture thereof by non-user, although it may constitute some evidence of an intention to abandon the right"

Responsibility of Diking Districts

Neither a diking district nor its commissioners are liable for damages under the Washington statutes.

In the repairing of one of its dikes, Diking District No. 12 of Washington used certain dynamite and dynamite caps. During the absence of the workmen a nine-year-old boy took some of the caps and in playing with them some days later, they exploded, blinding and otherwise injuring him. The minor sues both the district and the commissioners, but on a demurrer to the complaint, the Supreme Court of Washington, held in the case of Shimada vs. Diking District No. 12, 245 Pacific Reporter 916 (May 12, 1926) that neither was liable.

In exonerating the commissioners the court says: "Their authority is to 'manage and conduct the business affairs of the district', and their acts in that behalf, when within the scope of their authority, are the acts of the corporation, not their individual acts, and they are not bound to answer personally, merely because of their official relation to the corporation, either for its contracts or for torts committed by its subordinate agents or employees . . ." No direct or personal negligence of the commissioners is alleged. The court then holds that the Diking District is a public corporation and is not liable to answer for the personal torts of its officers, agents, or employees, in the absence of a statute expressly declaring them so liable, and that there being no such statute in Washington, the district could not be held liable.

OVERHEAD IRRIGATION

CONDUCTED BY WM. J. B. STEWART

OVERHEAD IRRIGATION EMERGING INTO FULL STATURE

OVERHEAD IRRIGATION is just emerging from its early infancy, and it is, naturally, still characterized by the growing pains that accompany the rapid emergence of any new business But, through hard-taught experience, continual reorganizations and revision of conceptions, accompanied by mechanical improvements, the overhead irrigation 'game' has grown into an industry—one which may safely be said to have a great future and large potentialities.

Overhead can hardly be said to have followed a plan; like Topsy, it has "just growed." A foothill citrus grower nine years ago, with Mother Nature's precepts to follow, planted the seeds of the industry. He was followed by a valley gardener a year or so later, and three or four other growers in various parts of the country two or three years later. These pioneers installed overhead sprays or sprinklers, several without knowledge of prior installations having been attempted. Lawn and garden sprays and sprinklers, the only type known to those pioneers, mothered the early days of the industry. From this origin has come an expansion comparable only to the quick response of an under-nourished thirsty orchard after the installation of an overhead system.

Present Growth Meteoric

The greatest increase in installed acreage has come during the past year, and the last six months have seen twice as much progress in this direction as the preceeding six months. At the present time, overhead contractors are doing more work than ever before. There are more than 250 acres of new systems being installed, at this writing, as closely as can be checked.

The record grows obsolete while it is being set down, as regards the total acreage now under overhead irrigation, but there are more than 1200 acres under systems of various kinds. The types of systems, or of sprinkler heads characterizing them, are as varied as the crops to which the acreages are planted, although three fourths of the installations thus far are on citrus groves.

Overhead systems are in satisfactory operation on oranges, lemons, limes, avocados, walnuts, alfalfa, garden truck, sub-tropical trees and shrubs, home orchards of various deciduous varieties, commercial apples, field onions and beans, field flowers and and bulbs, general nursery stock, private rustic and formal estates and public parks.

Re-Introducing This Department

MODERN IRRIGATION is glad to have the opportunity of re-introducing this department, devoted to overhead irrigation, in this issue. It will be a regular feature of the magazine in the future, conducted by William J. B. Stewart, an overhead consultant of extensive experience and broad acquaintance in this specialized division of irrigation.

Mr. Stewart is frankly and sincerely an advocate of overhead irrigation and a believer in its advantages. In championing it so outspokenly he speaks his own conviction based on his experiences and observations. Not all of his ideas on all phases of overhead matters will necessarily be shared, in full, by the publishers of Modern Irrigation, but he will welcome, as will the magazine, full and frank discussion of all problems and questions related to overhead by intelligent observers regardless of whether their standpoint be the same as that of the conductor of the department.—Editor.

Of the several general types of sprinklers, classified roughly according to the coverage of the individual head, the smallest total acreage is served by sprays, with their shorter coverage. A considerably greater acreage is found equipped with the rapidly moving short-coverage sprinklers—these are mainly on older installations. Probably not so large an acreage is equipped with medium-coverage, medium-speed, single action or simple two-arm sprinklers; and, lastly, the great bulk of installations are equipped with wide-coverage sprinklers, necessarily of slow rotation.

The methods of accomplishing this slow rotation are the patented features of the respective sprinklers of this class. It may be accomplished by vibration or counter-action being used to interrupt the hydro-dynamic rotation of the main nozzle, as in the Orr compound and Climax Sprinklers, pioneers of this type. The Browning and the Skinner are prominent among the wide-coverage gear driven sprinklers, the former being used on orchard and the latter on golf courses.

Among the various types mentioned, in addition to those named above, the following are the most prominent to date—Thompson, Hadden, Rose, Buckner, Vacher, the new Lark, Rainmaker.

Results Evaluated

While there is a great diversity of opinion among growers and close students of overhead irrigation, with regard to its effect on various pests, diseases, frost, June drop, etc., there apparently exists a unanimity of opinion among scores of overhead irrigators as to the general satisfactory results attained from their systems. The one possible exception is hardly a blot on the record of practical overhead irrigation, as it is an every-tree spray mist installation on very heavy soil, which is hardly showing the improvement usually obtained by overhead installation.

Although the results from overhead have been generally gratifying, there were a considerable number of systems which were installed during the earlier days with a net-work of small pipe, or were "thrown in" by some of the contractors without due regard to the hydraulic requirements for the proper and continued operation of a system. These have been the cause of considerable dissatisfaction and dissension, but, fortunately, most of the errors were such as could be corrected, at least to an extent sufficient to make the systems workable.

To be fair, perhaps some of the dissatisfaction may be chargeable to an excessively "finicky" attitude on the part of a few growers with regard to the even distribution of water by the sprinkler heads utilized. While this is an important point, all of the leading sprinklers can easily be adjusted to distribute the water sufficiently evenly within the limits of the circle they can cover. Certainly, so long as the water is well over every tree, overhead irrigation seems to

this writer to offer a tremendous advance in the difficult manual art of evenly distributing water over land, particularly when the land is of irregular gradient or light texture.

So, without an outstanding guiding hand and beset by many conflicting opinions, overhead irrigation has developed in the past few years through the appeal of a better, easier, cheaper way of irrigation, holding forth the promise of better health and production for trees and other plantings.

Organizations Co-operate

Credit is gratefully ascribed to the farms bureaus and advisors, farm publications and growers who have recorded their experiences for the guidance of overhead irrigators. Through their efforts hundreds of prospective users are now figuring on the proper system design and requirements and on the financing of the installation.

It is with a keen appreciation of the need of a guiding hand for the industry, a fountain head for authoritative, practical and seasoned advice on the hydraulics and mechanics of overhead systems, an open forum for ideas pertinent to the subject, that this department has been established by Modern Irrigation for its readers. Articles by leaders in the overhead industry and its allied lines will be printed regularly. News items of interest and value to prospective overhead irrigators will be presented and questions on the subject will be discussed or answered by experts as explained in adjoining columns.

It is your department. Your interest and co-operation will make it more valuable to you.

Farm Advisors Lead Tour of Overhead Information Seekers

Seventy-five machines and more than 130 persons were guests of the Agricultural Extension Service on June 24, when the citrus growers department of the Farm Bureau and the county farm advisors of Los Angeles and San Bernadino counties (Calif.), conducted a tour of seven overhead irrigation systems in the San Gabriel valley and foothills.

A. J. Brown, irrigation specialist of the Agricultural Extension Service delivered two short addresses at the McPherson and Johnson groves. He summarized the important findings of Prof. Wadsworth's recent detailed investigation of overhead irrigation as follows: 1. Overhead irrigation systems are costly. They restrict their use to valuable lands and crops. 2. Overhead systems distribute water more uniformly than any other system. 3. Experiences on light soil have shown very beneficial results from overhead irrigation. 4. The detailed designing of an overhead system requires the services of a competent engineer who will save the grower many times his fees.

C. J. Pegler's grove was first visited. His grove has been under an overhead system for some five years. He has a portable system that requires ten sets of his battery of sprinklers to cover the acreage. The small pipe works satisfactorily in his system. He said that at the present time he is raising more fruit with less labor and expense than he has ever before. He made the statement that he has had no brown rot gummosis since the installation of his overhead system. He pointed out the fact that this would tend to dispel any reports that overhead systems caused gummosis.

When the party reached the F. H. McPherson grove—sandy loam soil—they were told that the grove was last irrigated on May 10 with 2.4 acre inches of water. Recent soil auger tests to a depth of 4 feet have shown that ample moisture still remains in the soil. During the past year, the trees were watered with but 10.55 acre inches, but they have shown marked improvement over their condition of three years ago, according to the ranch manager.

Frank G. Webber, manager of the Sierra-Madre Citrus Association and newly elected president of the Lemon Men's Club, told the guests that he had noticed that the best colored oranges and the most evenly colored silver green lemons were coming from overhead irrigated groves.

C. M. Johnson discussed his problems of installation of wide coverage sprinklers, screening of ditch water and booster equipment. The pressure boosting costs on his Glendora grove offset his lessened ditch-water costs.

H. K. Needham opened the gates of his grove for the inspection of the procession. He reported a slight advantage in overhead irrigation methods as applied to his groves. He pointed out the dangers in spraying the groves too severely and in fumigating the growth that had been cleaned as a result of overhead irrigation.

The installations on the W. A. Johnstone and Meredith groves were seen on the way to California's largest installation of overhead equipment. A. M. Stephens, of La Verne, has 65 acres now under this method of irrigating.

OVERHEARD Among the OVERHEADS

A test plot installation has just been completed for the Placenta Fruit Company on a small acreage at Fullerton by A. E. Harris.

The Rose ranch, adjoining that of Dr. Matzen (at Escondido) has just had a five-acre installation made by F. L. B. Co. using new type Orr sprinklers. It is on side-hill land newly planted to citrus.

A fifteen-acre installation of Orr sprinklers has just been completed at Escondido, Calif., on avocados and citrus for Dr. Neil Matzen by S. H. Gerson. Of especial interest is a low pressure unit of special design that is operating satisfactorily on only fifteen pounds pressure.

W. A. Buckner, president of the Buckner Manufacturing Co. of Fresno, Calif., one of the leading manufacturers of overhead sprinklers on the Pacific Coast, was in Southern California the greatest part of June, visiting various installations in that territory in company with T. E. Watson, his Los Angeles distributor.

So far as known, the overhead system requiring the widest coverage from its sprinklers is that of Geo. Barfoot at Anaheim, (Calif.), where the 24-foot setting requires a throw of 120 feet in diameter and gets it from the Orr compound sprinklers used with sixty pounds pressure. The instillation is just being completed by Sam H. Gerson.

A new planting of avocados on the extensive Spadra (Calif.) estate of W. K. Kellogg, the "Corn Flake King" is to be irrigated with an overhead system being installed by Albert E. Harris. Although the installation is but four acres in extent, it is understood to be only the first of hundreds of acres which may go under overhead on this property. Extensive plantings of alfalfa under overhead are planned.

The Vindicator Company, one of the pioneer overhead sprinkler manufacturers, formerly located at Vernon, has taken up headquarters in Glendale, Calif. Fengal C. Orr, developer and patentee of several sprinklers, has associated with him J. C. McNaught, for years well known in golf-course irrigation circles. Their plans include a production plant in the Glendale industrial district in the near future.

SURVEY *of* HYDRAULIC DEVELOPMENT

As Shown by Official Records of the Month -- Local, State, and Governmental

Permits Issued

Among the more important permits to appropriate water issued by the Department of Public Works, Division of Water Rights of California, during the month of June, 1926, were the following:

Application No. 5042 (San Diego County) —Samuel W. Swan & Carl A. Davis, Room 9, Post Bldg, San Diego, Calif., for 2½ cubic feet per second and 33,000 acre feet per annum from San Felipe Creek, tributary to Salton Sea. To be diverted in Section 2, T 13 S, R 4 E, S. B. M. for irrigation and domestic purposes on approximately 20,000 acres in San Felipe Valley. Estimated cost $500,000.

Application No. 5046 (Sierra County)— Sierra Highland Mining Co., 401 Claus Spreckel's Bldg., San Francisco, Calif., for 5 cubic feet per second and 450 acre feet per annum from Lake Hawley and Hawley Meadows, tributary to East Fork North Fork Yuba River. To be diverted in Section 14, T 21 N, R 11 E, M. D. M. for mining purposes in Sections 33 and 34, T 21 N, R 11 E and Section 4, T 20 N, R 11 E, M. D. M. Estimated cost $60,000.00

Application No. 5047 (San Joaquin County)— Mrs. Louisa Stark, care of Ohm & Rabb, 517 E. Market St., Stockton, Calif., for 16.68 cubic feet per second from Salmon Slough and Middle River tributary to San Joaquin River. To be diverted in Section 23, T 1 S, R 5 E, M. D. M., Section 35, T 1 S, R 5 E, M. D. M., Section 27, T 1 S, R 5 E, M. D. M., for irrigation purposes on 1334.8 acres. Estimated cost $10,000.00

Application No. 5048 (San Joaquin County)—Helen H. Cleghorn, care of Ohm & Raab, 517 E. Market St., Stockton, Calif., for .22 cubic foot per second from Fourteen Mile Slough, tributary to San Joaquin River. To be diverted in Section 16, T 2 N, R 6 E, M. D. M., for irrigation purposes on 18 acres in Sections 16 and 17, T 2 N, R 6 E, M. D. M. Estimated cost $2,500.00

Application No. 5050 (Sonoma County)— Grand Lodge—Knights of Pythias of State of Calif., care of Jesse W. Carter, Redding, Calif., for .03 cubic foot per second and 7 acre feet per annum from Hood Creek tributary to Sonoma Creek. To be diverted in Section 18, T 7 N, R 6 W, M. D. M., for domestic and irrigation purposes in Section 24, T 7 N, R 7 W, M. D. M. Estimated cost $30,000.00

Application No. 5051 (Inyo County)—E. A. Ludwick, Box 674, Big Pine, Calif., for 3 cubic feet per second from Buckhorn Spring, tributary to Deep Spring Valley. To be diverted in Section 16, T 8 S, R 36 E, M. D. M., for mining and domestic purposes in Section 20, T 8 S, R 36 E, M. D. M.

Application No. 5052 (Inyo County)— Western Lead Mines Co., Beatty, Nevada, for .075 cubic foot per second from Willow Spring, tributary to Death Valley. To be diverted in Section 7, T 12 S, R 45 E, M. D. M., for mining and domestic purposes in Section 33, T 12 S, R 45 E, M. D. M. Estimated cost $10,000.00

Application No. 5053 (Inyo County)— Western Lead Mines Co., Beatty, Nevada, for .12 cubic foot per second from Big Spring, tributary to Death Valley. To be diverted in Section 2, T 12 S, R 44 E, M. D. M., for mining and domestic purposes in Section 33, T 12 S, R 45 E, M. D. M. Estimated cost $15,000.00

Application No. 5055 (Santa Cruz County) —Leonard & Holt, 220 Kearney St., San Francisco, Calif., for .20 cubic foot per second from Zayante Creek tributary to San Lorenzo River. To be diverted in Section 2, T 10 S, R 2 W, M. D. M., for domestic purposes on subdivision in Section 2, T 10 S, R 2 W, M. D. M. Estimated cost $25,000.

Application No. 5056 (Amador County)— Stephen E. Kieffer, Mechanics Inst. Bldg., San Francisco, Calif., for 300 cubic feet per second from Mokelumne River tributary to San Joaquin River. To be diverted in Section 15, T 5 N, R 10 E, M. D. M., for power purposes in Section 17, T 5 N, R 10 E, M. D. M. 9370 H. P. Estimated cost $1,500.000.

Application No. 5057 (Plumas County)— Feather River Tract Co., Room 804, 57 Post St., San Francisco, Calif., for 5 cubic feet per second from Dogwood Creek, tributary to Middle Feather River. To be diverted in Section 2, T 22 N, R 8 E, M. D. M., for power purposes in Section 35, T 23 N, R 8 E, M. D. M. 50 H. P. Estimated cost $15,000.

Application No. 5061 (Trinity County)— Big Creek Ranch Inc., care of N. D. Hopkinson, 68 Post St., San Francisco, Calif., for 40,000 acre feet per annum from Big Creek tributary to Hay Fork of S. Fork Trinity River. To be diverted in Section 6, T 32 N, R 11 W, M. D. M., for irrigation purposes on 22,000 acres in Townships 31 and 32 N. Ranges 10, 11 and 12 W. M. D. M. Estimated cost $200,000.00

Application No. 5064 (San Joaquin County) John H. Masters, care of Ohm & Raab, 517 E. Market St., Stockton, Calif., for .90 cubic foot per second from Burns Cutoff tributary to San Joaquin River. To be diverted in Section 12, T 1 N, R 5 E, M. D. M., for agricultural purposes on 72.4 acres in Section 14, T 1 N, R 5 E, M. D. M. Estimated cost $5,000.00

Application No. 5068 (Mono County)— Nevada California Power Co., care of W. L. Huber, 1st National Bank Bldg., for 30 cubic feet per second from Leevining Creek tributary to Mono Lake. To be diverted in Section 20, T 1 N, R 25 E, M. D. M., for power purposes in Section 16, T 1 N, R 25 E, M. D. M. Estimated cost $1,170,022.00

Application No. 5069 (Siskiyou County) —Geo. H. Cory, Callahan, Siskiyou Co., Calif., for 1 cubic foot per second from Little Carmen Creek, tributary to Grouse Creek. To be diverted in Section 29, T 40 N, R 7 W, M. D. M., for mining and domestic purposes in Section 29, T 40 N, R 7 W, M. D. M.

Applications Filed

Among the applications for permits to appropriate water filed with the State Department of Public Works, Division of Water Rights, (California) during the month of June were the following:

Permit No. 2516, Application No. 4841 (Yolo County) Issued to Mrs. P. J. Braun, Grafton, Calif., June 1, 1926, for 6.93 cubic feet per second from Sacramento River in Section 6, T 10 N, R 3 E, M. D. M. for irrigation of 277.07 acres of rice near point of diversion. Estimated cost $4,500.

Permit No. 2517, Application No. 4889 (Lake County) Issued to W. F. Detert, San Francisco, Calif., June 1, 1926, for 6.25 cubic feet per second and 600 acre feet per annum from Bucksnort Creek in Section 9, T 10 N, R 6 W, for use for irrigation of 1002 acres in Guenoc Rancho. Estimated cost $100,000.

Permit No. 2519, Application No. 3657 (San Benito County) Issued to Peter L. Swanson & Lillian J. Swanson, Hollister, Calif., June 4, 1926, for 1.4 cubic foot per second from San Benito River in Section 5, T 14 S, R 6 E, for irrigation of 186 acres near point of diversion. Estimated cost $5,000.

Permit No. 2529, Application No. 4768 (Amador & Calaveras Counties) Issued to East Bay Municipal Utility District, Oakland, California, June 15, 1926, for 375 cubic feet per second and 217,000 acre feet per annum from Mokelumno River in Section 26, T 5 N, R 10 E, for power purposes in Section 26. 13849 T. H. P. to be developed. Estimated cost $6,000,000.00

Permit No. 2534, Application No. 1097 (Mono County) Issued to Walker River Irrigation District, Yerington, Nevada, June 18, 1926, for 35,000 acre feet per annum from West Walker River in Section 27, T 6 N, R 22 E, for irrigation of 160,000 acres, stock and domestic near point of diversion. Estimated cost $167,500.00

Permit No. 2535, Application No. 1098 (Mono County) Issued to Walker River Irrigation District, Yerington, Nevada, June 18, 1926, for 115,000 acre feet per annum from West Walker River in Section 17, T 6 N, R 23 E, for irrigation of 160,000 acres near point of diversion.

Permit No. 2536, Application No. 1389 (Mono County) Issued to Walker River Irrigation District, Yerington, Nevada, June 18, 1926, for 57,000 acre feet per annum from East Walker River in Section 34, T 6 N, R 25 E, for irrigation of 160,000 acres near point of diversion. Estimated cost $330,000.00

Permit No. 2538, Application No. 2615 (Mono County) Issued to Walker River Irrigation District, Yerington, Nevada, June 18, 1926, for 200 acre feet per annum from unnamed stream in Section 27, T 10 N, R 22 E, for domestic and irrigation of 160,000 acres near point of diversion. Estimated cost $918,000.00

Permit No. 2539, Application No. 2342 (Nevada County) Issued to James F. Dunn, Salt Lake City, Utah, June 21, 1926, for 97 acre feet per annum from South Wolf Creek in Sections 19 and 30, T 15 N, R 9 E, for irrigation of 55 acres near points of diversion. Estimated cost $7500.00

Permit No. 2542, Application No. 4928 (Tuolumne County) Issued to Oakland-Piedmont Council Boy Scouts of America, Oakland, Calif., June 22, 1926, for 0.1 cubic foot per second from Middle Fork Tuolumne River in Section 15, T 1 S, R 19 E, for domestic and recreational purposes in Section 10. Estimated cost $2050.00

Permit No. 2543, Application No. 2665 (Trinity County) Issued to Humboldt Placer Mining Co., 427 East McLeod St., Stockton, Calif., June 22, 1926, for 75 cubic feet per second from Stuarts Fork of Trinity River in Section 31, T 36 N, R 9 W, for mining purposes near point of diversion. Estimated cost $250,000.

Permit No. 2544, Application No. 2666 (Trinity County) Issued to Humboldt Placer Mining Co., 427 East McLeod St., Stockton, Calif., June 22, 1926, for 25 cubic feet per second from Owens Creek and unnamed South Branch of Owens Creek in Section 12, T 35 N, R 10 W, for mining purposes near point of diversion. Estimated cost $7,000.00

Permit No. 2545, Application No. 2667 (Trinity County) Issued to Humboldt Placer Mining Co., 427 East McLeod St., Stockton, Calif., June 22, 1926, for 25 cubic feet per second from Van Matre Creek in Section 24, T 33 N, R 10 W, for mining purposes near point of diversion. Estimated cost $5600.00

Permit No. 2547, Application No. 4838 (Riverside County) Issued to James Kincheloe, Corona, Calif., June 23, 1926, for 3 cubic feet per second, from Bedford Canyon in Section 36, T 4 S, R 7 W, for domestic use and irrigation of 245 acres near point of diversion. Estimated cost $18,000.

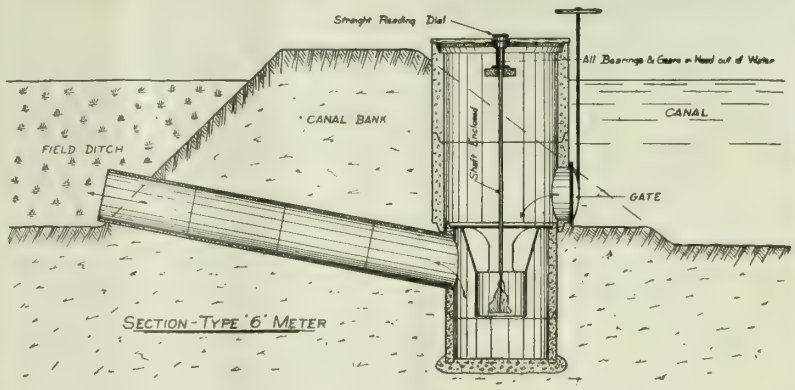
Permit No. 2550, Application No. 4881 (Marin County) Issued to Bolinas Public Utility District, Bolinas, Calif., June 23, 1926, for 1 cubic foot per second from Arroyo Hondo Creeks in Section 9, T 1 N, R 8 W, for municipal purposes for Bolinas Public Utility District. Estimated cost $50,000.00

Permit No. 2551, Application No. 1990 (San Louis Obispo County) Issued to City of San Louis Obispo, Calif., June 23, 1926, for 2.32 cubic feet per second from Lopez Creek in Section 9, T 31 S, R 14 E, for municipal purposes in said city. Estimated cost $600,000.00

Permit No. 2553, Application No. 2302 (San Luis Obispo County) Issued to Victor A. Bentson, San Francisco, Calif., June 23, 1926, for 4.74 cubic feet per second from Arroyo Grande Creek in Ranchos Corral De Piedra & Santa Manuela within T 31 S, R 14 E, for irrigation of 378.81 acres near point of diversion. Estimated cost $20,000.-00.

Permit No. 2554, Application No. 4869 (Plumas County) Issued to Feather River Power Co., San Francisco, Calif., June 25, 1926, for 5 cubic feet per second from Pebble Creek and 3 unnamed branches of Milk Ranch Creek in Sections 6 and 7, T 24 N, R 7 E, for power purposes in Section 29, T 24 N, R 6 E. 1450 T. H. P. to be developed. Estimated cost $7,700,000.

The RELIANCE METER



THE "Type 6" Reliance Irrigation Meter offers you standardized permanent construction at a very low first cost. Their sustained efficiency with a minimum of upkeep has been proven by 12 years usage. Cut shows installation of the 4 sec. ft. size in 24 and 30-inch concrete pipe. This is the standard type of setting adopted by many irrigation districts in Texas and elsewhere who are now equipping all their deliveries with this device. The "Type 6" meter is furnished in sizes ranging from ½ up to 16 sec. ft.

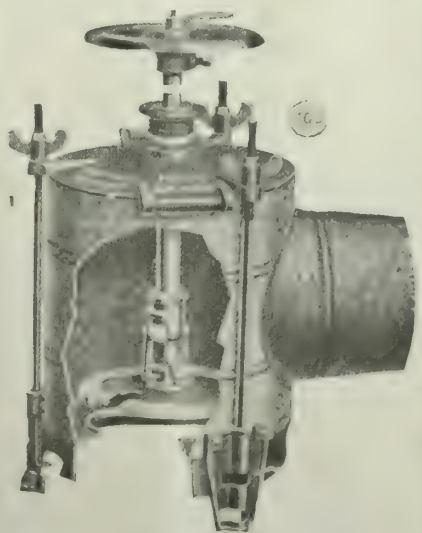
Alfalfa Irrigation
MADE EASIER WITH
The Martin Portable Hydrant



Martin engineers, specialists in utility irrigation appliances, never designed a more serviceable piece of equipment than the MARTIN PORTABLE HYDRANT. Its use with MARTIN Alfalfa Valves Type B and Type Q enables the irrigator to control the direction of flow easily. Four checks can be irrigated handily and the operator knows exactly the amount of water each check is getting.

The spout of the hydrant can be turned in any direction. Two hydrants are generally used on one pipe line. While one is set and operating, the other can be moved to the next valve and set up ready to operate. Surface pipe can be attached to hydrant before valve is opened. The valve is opened and closed by the wrench built into the hydrant. After the entire field is irrigated, the hydrants can be removed and placed in the tool house. As the Type B valve is flat on top, there are no obstructions in the field to catch the mower or rake.

We manufacture the original line of Irrigation Appliances Outlet Valves, and Cut-off Gates for the definite division of water over the field from Concrete Pipe Lines.

IRRIGATION PIPE

That will give years and years of service

Uninterrupted service—because **Montague Steel Products** are made to give satisfactory service. Once installed you'll not have to replace **Montague Pipe** for generations.

These catalogs FREE on request.

Montague Well Casing.....5-A
Riveted Steel Pipe.....5-B
Surface Irrigation Pipe.....5-C

Also Oil and Water Tanks—Siphons—Stacks and Flumes—and a genuine safety water tube boiler, 1 to 20 h. p. and up. Prices upon application.

MONTAGUE PIPE & STEEL CO

San Francisco California

at your favorite hotel when you come to San Francisco.

But here's a tip—come in to the Plaza Hotel for your meals—you'll be delighted with the cool dining room, the delicious food—the quiet efficient service.

Prices? Most reasonable! A splendid luncheon for 65c or—table d 'hote dinner for $1.00

PLAZA RESTAURANT

Entrance also through Hotel Plaza lobby

OVERHEARD AMONG THE OVERHEADS

(*Continued from Page 49*)

The utilization of natural gas for booster pump power at a cost said to be but a fraction of the cost of electricity is a feature of the 18-acre system of oranges being installed for J. C. Gapp in the North LaVerne district by Clarence H. Thomas, one of the pioneer contractors. A Buda gas engine entailing an initial investment about 25 per cent greater than that of electric motor equipment is being used in the pump house and the new Lark sprinkler is to be installed.

An additional acreage in the Anaheim district has been installed for P. J. Weisel by the Browning Construction Company. Different systems and sprinkler heads are being tried out by Mr. Weisel, who is an extensive grower in various districts. His experience on the sandy Anaheim soil has been interesting with regard to the water used by the overhead as compared with the furrow method. His plant formerly pumped 100 inches of water for 48 hours to get over the twenty acres but through the overhead 50 inches of water gives it a better irrigation in four units in twenty-four hours total time of operation. This figures a quarter of the water formerly used and the leached condition of the soil is being replaced by cover crop humus.

WHAT IS *YOUR* PROBLEM

FREQUENT requests for authoritative, unbiased information on overhead irrigation systems, co-ordinating the hydraulic, mechanical and agricultural requirements thereof, has led MODERN IRRIGATION to secure for its readers the services of Lippincott and Stewart, consulting hydraulic and overhead irrigation engineers.

In this department, questions of general interest to overhead irrigators will be answered for our readers. Should special or earlier answers be desired, a stamped addressed envelope should accompany each inquiry. There is no charge for this service.

How much water will I need to run sprinklers on my eight acres? Can I get it through my two-inch meter? G. D. H.

Overhead irrigation systems can operate on from five to eight miners' inches of water per each acre under operation. Proper engineering of a system will take into account primarily the volume and pressure available, the soil porosity and surface gradient. With a pressure upward of fifty pounds your two-inch meter will admit sufficient water to operate up to two acres at one time, and a four-unit system would be necessary, unless, of course, the supply and the meter could be enlarged.

We have so much lime in our water that it quickly "limes up" on faucets and fittings. I believe it would be unsuitable for sprinkling onto vegetation. Please let me know what you think about such a condition?
S. A. R.

We have encountered this condition and opinion in two other localities. Preliminary experiments have shown no adverse effects on foliage but on account of the serious possibilities we are awaiting the results of conclusive tests which are being made by recognized plant chemists. Such conclusions will be reported in these columns.

Can I utilize my concrete line in any way in changing over from furrow to overhead irrigation? E. L. C.

No old type of concrete line can handle water under pressure sufficient to operate any standard sprinkler equipment. Possibly water could be conducted from the source or entrance to the property to the most economical booster pump location through the concrete line as laid. However, a new high-pressure type of concrete pipe is being developed and manufactured that offers possibilities for use in this field. Names of companies manufacturing such pipe will be supplied upon request. An article on this subject will appear in these columns in the near future.

OREGON

Among the more important applications for permit to appropriate water filed in the office of Rhea Luper, State Engineer of Oregon, during June, 1926, were the following:

Lewis E. Springer, William N. Palsgrove, and Albert M. Davis of Dufur, covering the appropriation of flood and surplus waters from Fifteen Mile Creek and Tamarack Creek for irrigation of 30 acres in Wasco County.

Jess Elliott of Copperfield, covering the appropriation of water from Pine Creek for irrigation of 10 acres, for the development of 3 theoretical horsepower, and to supply fish ponds in Baker County, at a cost of $1,000.

John C. McFarland of LaGrande, covering the appropriation of water from Grande Ronde River for irrigation of 30 acres in Union County.

Bear Creek Land Company of Portland, covering the appropriation of seepage water for domestic purposes including garden irrigation; and also covering the appropriation of water from an unnamed spring for domestic use including garden irrigation in Clackamas County, at a cost of $10,000.

Wyatt Brothers of Mt. Hood, covering the appropriation of water from East Fork of Hood River for development of 30 theoretical horsepower in Hood River County, at a cost of $3,000.

Cary V. Loosley of Fort Klamath, covering the appropriation of water from Lenz or Big Springs Creek for irrigation of 1,320 acres and for stock water in Klamath County, at a cost of $1,000.

H. G. Masterson of Elgin, covering the appropriation of water from Wallowa River for irrigation of 60 acres in Wallowa County.

Mrs. E. M. Benson of Nyssa, covering the appropriation of water from the Nyssa-Arcadia Drainage Ditch for irrigation of 20 acres in Malheur County.

E. G. White of Hillsboro, covering the appropriation of water from an unnamed stream for irrigation of 17 acres in Washington County.

E. W. Kelly of Hood River, covering the appropriation of water from an unnamed spring for irrigation of 20 acres in Hood River County.

William M. Teeter of Elgin, covering the appropriation of water from Gordon Creek for irrigation and supplemental supply for 109 acres in Union County.

J. P. Abbott of Wapinitia, covering the appropriation of water from Tapa Spring for domestic use including stock water, and for irrigation of 20 acres in Wasco County.

Edward Bryant, et al, of Redmond, covering the appropriation of water from Lake Creek and Suttles Lake for irrigation of 12,000 acres in Jefferson County.

City of Warrenton, covering the appropriation of water from Lewis and Clark River for domestic and general municipal purposes at an estimated cost of $500,000.

Theo Lengele of Route 2, Salem, covering the appropriation of unnamed springs tributary to Rickreall Creek for domestic supply and irrigation of 30 acres in Polk County, at an estimated cost of $1,000.

City of Monroe covering the appropriation of water from Hewitt Spring for municipal water supply in Benton County, at an estimated cost of $5,000.

W. B. Lindsay & E. J. Schumacher of Merlin, covering the appropriation of water from Brockman Ditch from Quartz Creek for irrigation of 50 acres in Josephine County, at an estimated cost of $400.

A. E. & Sally Bush of Salem covering the appropriation of water from Labish Drainage Ditch and two springs for irrigation of 169.77 acres in Marion County at an estimated cost of $2,500.

Henri Walloert of Baker, covering the appropriation of water from Goodrich Creek for irrigation of 100 acres.

B. A. Huff, Dick Koopman and John Liggett of Pine, Baker County, for appropriation of water from Corral, Lake Fork Pine and Bigger Creeks, for the irrigation of 350 acres. No estimate given.

E. C. Wren of Hood River, covering the appropriation of water from Indian Creek for irrigation of 17 acres, at an estimated cost of $1000.

Breitenbush Mineral Spring Co. of Portland, covering the appropriation of water from Breitenbush River, for 375 theoretical horsepower, at an estimated cost of $2,500.

AMONG OUR CONTRIBUTORS

Editorial Jottings About Current and Forthcoming Feature Articles, Dealing With Practical Problems of Hydraulics, and the Men Who Have Written Them

R. V. MIEKLE, who served as chief engineer in the construction of the Exchequer project began his technical engineering work in 1906 as a draftsman in the water department of the city of Portland, Oregon. For six years he served in various capacities on city water supply, power and irrigation projects in the northwest. He was graduated from draftsman to instrument man, and from instrument man to assistant engineer. He spent one year with the United States Department of Agriculture in California. In 1914 he was made chief engineer of the Don Pedro project for the Modesto and the Turlock Irrigation districts. Until the completion of the Exchequer Dam, he served as chief engineer on the project, and resigned on its completion to give place to a permanent operating organization. Mr. Meikle has written the leading article of this issue, summarizing in modest style the truly epic story of the Exchequer.

DOUGLAS G. MCPHEE, who tells of his interview with the Bent brothers on the construction of the Exchequer dam, has been executive editor of MODERN IRRIGATION since its establishment a year ago.

L. J. FLETCHER is professor of agricultural engineering at the University of California, branch of the College of Agriculture. He has been extremely active in the advancement of agricultural engineering as a distinct branch of the profession.

STUART B. SHOW, District Forester of the California district, United States Forest Service, writes this month on "How You Can Aid in Protecting the Forests." Mr. Show is a graduate of Stanford University, and received his technical education in forestry at the Yale Forest School. Born in Nebraska, he early came to California with his father, and has been an officer in the United States Forest Service for more than sixteen years. He started as a student forester on the Shasta National forest and has steadily advanced to the position which he now holds. His work has taken him into practically every forest in the state of California.

PAUL BAILEY'S personal sketch of the late W. F. McClure was written at the request of the editors of MODERN IRRIGATION. Because of his intimate contact with Mr. McClure, and because of his knowledge of his former chief's work in the irrigation field, Mr. Bailey is the man best suited to describe Mr. McClure and his service. Mr. McClure who was chief engineer for the State of California and head of the State Department of Public Works,

WILLIAM J. B. STEWART

died June 22. He was stricken by an attack of heart disease while on an inspection tour of the Sly Park dam site near Placerville, California. Mr. Bailey has for some time been deputy state engineer but he has written his sketch of Mr. McClure in the capacity of a friend and admirer who had exceptional opportunity to know the man and the work which he accomplished.

R. P. LEHR is associated with the Killefer Manufacturing Company, Los Angeles. He has given many years of study to irrigation, especially to cultivation and soil chemistry. A wide range of experience and a bent for careful observation have peculiarly fitted him to write on the value and effect of cultivation on irrigation. His article this month deals with a subject that is vital and basic in irrigation practice.

ROY W. CARLSON, whose article descriptive of the tests and measurements which are being made on the Engineering Foundation's test dam on Stevenson Creek appears in the hydraulic engineering department of this issue, is connected with the Southern California Edison Company, and has been for some time active in that company's work in the Big Creek region. Mr. Carlson received collegiate training at the University of Redlands (Calif.) and subsequently did graduate work and research study in physics at the California Institute of Technology in Pasadena, California. During the years 1924-25 he was acting associate professor of physics at the University of Redlands.

RAY L. DERBY, whose article describes his experiences with the sulfur dioxide problem, was born in Brooklyn, N. Y., June 14, 1898, received his preparatory education in the schools of Los Angeles County, and was graduated from the University of California in 1922, after having spent some time in the U. S. Army and in surveying work for Los Angeles County, and the California Highway Commission before receiving his degree.

While in college, Mr. Derby won the James Munroe McDonald Scholarship for Sanitary Engineering Students. Upon graduation, he entered the employ of the California State Board of Health as assistant sanitary engineer, resigning in July, 1923, to accept his present position as sanitary engineer with the firm of Salisbury, Bradshaw & Taylor, consulting engineers of Los Angeles.

CARL E. GRUNSKY is a past president of the American Society of Civil Engineers. Mr. Grunsky is a native of California but obtained his higher education in Europe, in Germany and England. He ranks today as one of the best known of the engineers of the West and entire country. He is a member of the Board of Editorial Advisors to MODERN IRRIGATION.

WILLIAM J. B. STEWART is a consulting hydraulic and overhead irrigation engineer. He introduces this month in MODERN IRRIGATION a new department which will run regularly in the future, dealing with practical overhead irrigation problems.

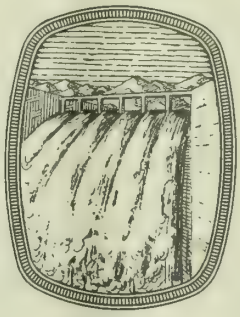
PETROLEUM WORLD 626 S. SPRING ST., LOS ANGELES, CALIF. MODERN IRRIGATION

PAUL BAILEY

Who was appointed California State Engineer and Director of Public Works on July 17 to succeed the late W. F. McClure. Mr. Bailey has for some time been deputy state engineer, working hand in hand with his late predecessor. The report which he submitted to Governor Richardson last month, concerning the future water supply for Southern California, a subject of practical interest to engineers and water developers throughout the West, is printed in full in this issue of MODERN IRRIGATION.

MODERN Irrigation
The Magazine of Applied Hydraulics



Volume II AUGUST, 1926 Number 8

The Progress *of* Irrigation

THE tremendous advance of irrigation can be perceived, in proper perspective, only as one draws away from individual projects and views all projects as one huge movement to bring fertility to hitherto arid communities. Controlling nature's forces for man's use is nowhere practiced with greater skill, or with more consummate success, than in Western America, where, seemingly every month brings the inauguration of another big water development.

The number of projects planned, under construction, or recently completed, when viewed in panorama, amaze one with the immensity of their physical—as well as their fiscal—aspects. Only a review of projects now in the making can give the reader an adequate conception of the progress of irrigation.

The Exchequer Dam, the most recently completed of the larger projects, has begun to function. Members of the Merced irrigation district, which it serves, have expressed themselves as being in favor of a managerial form of government instead of a highly complicated machine, such as the board of directors had, it is reported, originally arranged for.

The Nevada Irrigation District reports that fourteen hundred men have been employed and that work is progressing rapidly on the project as a whole. A chain of 20 camps has been established to house the men working at the various phases of construction. The great rock dam at Bowman is approximately 40 per cent completed. Seven hundred and fifty acres of timber are being removed to provide for further storage space in the reservoir area. The ten mile conduit is rapidly taking form, and the long bore that will go from end to end of the project has been started. It is interesting to note that the site for the district's present construction was selected 50 years ago by Hamilton Smith.

On the Mokelumne project, Oakland, contractors have been instructed to proceed with the construction of the concrete dam and power house at Lancha Plana, the district having received the permit from the Federal Power Commission. The contract price has been set at $3,081,378. The contractors have been instructed to proceed with the Lancha Plana tunnel on a price basis of $624,045. Camps have been established and excavating has begun on the east heading of the Claremont Tunnel.

Other important irrigation projects

include the winning of a fourteen year struggle by the Pecos, Texas, Irrigation District for the right to construct a dam on the Pecos River for the irrigation of some 110 miles along the river.

Bids will be called for soon on the construction of the $5,500,000 multiple-dome type, concrete Coolidge Dam for the United States Indian Service near San Carlos, Arizona.

Bids will be called for the $3,000,000 Gibson concrete dam, Sun River project for the United States Reclamation Service at Fairfield, Montana.

A bond election will soon be held for the $1,250,000 earth fill dam to be erected in connection with a canal system for the Lovelock Irrigation District, Nevada.

The state of Sonora, Mexico, reports a 10,000,000 dollar project for a dam and canal system. The Mexican federal government has given instructions to proceed with the first unit of its vast irrigation program with the initiation of work on the Aguas Calientes project.

A bond election is in the offing for a $1,750,000 project to include concrete dam, canals, and syphon for the El Doroado Irrigation district, Placerville, California.

The engineering Commission of the Kings River Water Storage District, California, will soon file a report on the proposed $20,000,000 Pine Flat project.

First concrete has been poured for the Frog Tanks Dam, Maricopa County Water Conservation District, Arizona. Seven miles of transmission power lines have been completed with the establishment of the construction camp. Four hundred men are employed on the project, working in three shifts, with the entire layout flood lighted. This will be what is said to be the highest multiple arch dam in the United States when completed.

The Horse Mesa dam in Arizona, when completed, will be three hundred feet high and fifty-three feet thick. Concrete pouring has started on this project. It is estimated that over 40,000 horsepower of hydro-electric energy will be developed when the dam is completed in April, 1927.

Ninety-one thousand cubic yards of concrete will be involved in the Melones Dam, San Joaquin and Oakdale Irrigation District, California. The dam is now over 150 feet high, and will be completed by September, 1926, it is said.

Earth fills on both ends of the American Falls Dam, U. S. Reclamation Service, Idaho, have been sprinkled and rolled. Over a thousand cubic yards of concrete is being poured daily with a large crane and a two-yard bucket. Some 130,000 cubic yards of concrete, 1,300,000 pounds of reinforcing steel, and 1,800,000 pounds of gate and penstock metal have been installed to date. Four hundred and twenty-five men are working to complete the dam by June 1927.

The reader will look at this photograph and probably wish that by some magic or other he might be transported to this delightful spot. The most remarkable fact about the locality would escape him, however, if he did not know that a few short years ago there was nothing here but sandy, barren waste. Fertilization and irrigation turned the trick.

The first concrete has been poured on the dam that will be the highest of all types in the United States near San Fernando, California. This is the Pacoima Dam, one of the important flood control projects of Los Angeles County, California. It has been estimated that the dam will take approximately a year to complete.

These are projects under way in the United States alone. When one considers that other irrigation works are bringing fertility to the soil the world over—in Mesopotamia, Mexico, Spain and Australia—some idea of the magnitude of the movement can be conceived.

The discouragement and low morale which recently existed on some of the Federal reclamation projects in the West have been suplanted by a spirit of confidence and optimism, according to a detailed special report made in July by Reclamation Commissioner Elwood Mead to Secretary Work.

Good Judgment is *Half-way Between* Arbitrary Rules *and* Guesswork

By CHARLES A. JENSEN

General Superintendent, Limoneira Ranch, Santa Paula, Calif.

IT IS usually assumed that the most favorable percentage of moisture in soil for best citrus tree growth is what is called the "optimum" moisture content, and that the nearer this moisture condition can be obtained the better. Without discussing now whether this broad assumption is true, it is the condition of soil moisture that one intuitively likes to maintain. The term "optimum" soil moisture is a loose one in meaning, and it covers a wide range of soil moisture percentage depending upon the physical texture of the soil. Before using the term any further it may be desirable to explain the general meaning of it from a definite point of view.

A number of years ago Drs. Briggs and Shantz in the Bureau of Plant Industry of the U. S. Dept. of Agriculture, determined experimentally the amount of moisture left in different types of soils after plants of various kinds had been grown in them long enough to go into permanent wilt. The term "permanent wilt" in this work meant that the plants had used up so large a proportion of the soil moisture that the plants, still in their soil containers, remained in a state of wilt when transfered to a chamber saturated with water vapor.

An interesting result found was the important practical point that when different types of plants were grown in the same type of soil, each type of plant left in the soil approximately the same percentage of moisture when the plants wilted and could not recover their turgidity when brought into a vapor saturated air.

That is, a grain plant, a corn plant, or a cactus plant, and other types of plants used, left approximately the same percentage of moisture in any one type of soil when the "permanent wilting" point had been reached. The percentage of moisture left in the soil when this plant condition obtained was called the "wilting coefficient," and this percentage varied with the physical texture of the soil used. This finding incidentally refutes an opinion sometimes heard expressed that plants take moisture from the air when they cannot obtain the necessary amount of soil moisture to maintain growth. A moist air simply retards the transpiration of the plant because of the higher vapor pressure of the moist air surrounding the leaves; the plant does not take into its system enough "air moisture" directly to be of economical consideration.

Defines "Moisture Equivalent"

When a handful of soil is put into a tube which has a perforated bottom, and the soil saturated with water, some of the soil water will drain away, but the soil will hold a certain amount of moisture against the pull of gravity. The investigators above-named found that when they subjected a water-saturated soil to a centrifugal force equal to one thousand times the pull of gravity that the percentage of moisture left in the soil bore a certain relation to the amount of moisture left in the same soil when plants were grown in it to the wilting point. The percentage of moisture left in soil after being subjected to a pull equal to 1000 times the pull of gravity for about 30 minutes was called the "moisture equivalent". The moisture equivalent thus determined in the laboratory divided by 1.84 gives approximately the wilting coefficient.

Now to get back to the term "optimum soil moisture." It was found that the moisture equivalent approximated the optimum soil moisture content. In a light or sandy soil, the optimum is a little higher than the moisture equivalent; in a medium loam soil it is about the same; in a heavy or clay soil it is somewhat lower. The "available moisture" in a soil is considered to be the difference between the moisture equivalent and the wilting coefficient. Irrigation control, then, carried to its logical limits, would consist of making moisture determinations of the soil under consideration and comparing the amount found with the wilting coefficient of the same soil as determined in

LEFT: Men's dormitory, in which single men on the Limoneira are comfortably housed. RIGHT: Irrigating Limoneira lemons. These large trees have their root systems throughout the entire soil area and require full irrigation. The soil in this part of the ranch is so open that a five-minute run of about 10 inches in a furrow completes the irrigation. Compare with opposite extreme, *illustrated on Page 12*

the laboratory. Then the question arises, whether to irrigate or not, and how much water to apply.

Theoretical Considerations Applied

After these few preliminary remarks concerning the principle underlying soil moisture control, we will consider the specific methods used in handling the soil moisture problems on the various divisions of the Limoneira Ranch. From the foregoing discussion it appears that it is a simple matter to determine the amount of soil moisture present and apply water when necessary. Field conditions present problems quite different from that of soil moisture determination. In what relation to the tree shall the soil sample be taken? What depth of soil moisture is of significance to the tree growth? Are the trees large or small, thrifty or unthrifty? How will irrigation and the accompanying grove operations affect lemon picking? What are the weather conditions going to be in the immediate future? Is the water supply of each irrigation division such that a given number of groves can be irrigated by a certain time?

Irrigating lemons on the Limoneira Ranch. These trees are not yet using all the soil; hence the furrow centers are not being irrigated. This particular soil type requires a run of about 24 hours of penetration.

Some of these questions, and others that arise, often without warning, can be answered definitely, and others, from the nature of things, cannot. The general complication is such that after considering the factors in their entirety, one of which is time and expense, we decided early in the work that it was not practical to attempt to control irrigation definitely by constant soil moisture determinations. We make soil moisture determinations, but only to train ourselves to judge off-hand in the field the amount of soil moisture present, and the time to irrigate is decided on the spot. We have had the moisture equivalent and the wilting coefficient determinations made on the representative soil types and train ourselves to tell in the grove how much moisture is present, and to tell the irrigation foremen how much water to apply and when.

In what relation to the tree should the soil sampling be done? We know from numerous observations, some opinions to the contrary notwithstanding, that the soil immediately under the tree is well supplied with fibrous roots which use water in considerable quantity. This is the first soil area that gets dry. The drying of the soil extends gradually from under the tree to the skirt of the tree and the last area to get dry is out in the furrow centers; notwithstanding the fact that the former area is in the shade and the latter in the sun. In many groves, depending on the general tree conditions, the furrow soil area never gets dry enough to approach the wilting coefficient.

Depth of Soil Moisture

What depth of soil moisture is of significance to lemon tree growth? It has been shown in other areas that about 80 per cent of the feeding root system is in the top 30 to 36 inches of soil in a medium loam; about 90 per cent in the top 30 inch soil layer in a clay soil; in sandy soils the distribution was found to be deeper. We have made no such investigations on this ranch, but correlating soil moisture conditions with the tree condition, we know that by far the most of the lemon root systems in most of our soils is in the first three feet; on certain of our soil types in the first 2½ feet; and on some of our sandier types we consider 3 or 4 feet of soil in our irrigation control.

This pictures to us the following:

The volume of soil moisture that is vital to the lemon tree can be considered as an inverted cone, the drying beginning near the tree trunk and the cone drying gradually from the top down and from the center out. The irrigation control problem is to decide how large to permit this cone to become. In a grove of very large thrifty trees of about 112 trees to the acre, the cones easily meet in the furrow centers, rows about 24 feet apart. In groves of medium sized trees and in others of unthrifty trees, the amount of soil moisture in the furrow centers concerns us not at all; in fact they have but very little water applied to them.

Try New System

It was decided last year to test the effect of irrigating closer to the trees than was customary. A grove of large Lisbon trees, 10 years old, rows about 26½ feet apart, was selected for the experiment. The average distance between the centers of the inside furrows was about 10 feet in the row furrowed as usual and about 6 feet in the row furrowed closer to the tree. As the lateral movement of the irrigation water was about 18 inches from the center of the furrow, there was an unirrigated strip of land in the tree row of about 7 feet wide in the row furrowed as usual, and a strip about 3 feet wide in the row with the furrow closer to the tree.

A set of lemon fruits was measured periodically on each row of trees, one set being begun on April 30, and terminating on Sept. 23. Measurements of another series was begun on July 31 and terminated on Nov. 27. Table No. 1 gives the data obtained in a condensed form. The results show that putting the inside furrow closer to the tree increased the average size of the fruit by about one packing size, produced larger green fruit and a smaller percentage of yellow fruit. Measurements of the second and later series of fruits showed a gain of a little less than one-half packing size from July 31 to Nov. 27. Rain

TABLE NO. 1.—Growth of lemons on trees irrigated so as to leave: (1) 7 feet of dry soil in the tree row and: (2) 3 feet of dry soil in the tree row.

Remarks	Aver. gain in Dia. of all fruits 4-30 to 9-23		Aver. gain in Dia. 4-30 to 9-23 in 16th inch		Percent Yellow Fruit
	In 16th in.	In percent	Green Fruits	Yellow Fruits	on 9-23
7 ft. dry strip	12.5	62	14.4	11.6	65
3 ft. dry strip	14.4	75	15.6	13.4	49

at that time interfered with the continuation of the experiment.

These experiments partially answer the question of what soil area is most important in supplying soil moisture to the lemon tree. Accordingly we examine most closely the soil moisture under the tree, or at least under the skirt of the tree. The soil dries out from the surface downward, and when we find that the soil under the skirt of the tree or just outside has dried out to about the wilting coefficient to about 18 to 24 inches quite uniformly we find it advisable to irrigate soon. I say uniformly; it is surprising how much faster the soil dries out on the sunny side of the tree. Dry soil to a depth of 18 to 24 inches on the sunny side of the tree only, does not necessarily call for irrigation because the other side of the tree may be plentifully supplied with soil moisture. The experiment given above also gives us reason for the practice of frequently irrigating with only two furrows on each side of the tree, letting the furrow center area wait till the next irrigation.

Is Optimum Advisable?

Is the maintenance of an "optimum" soil moisture supply advisable? It was attempted to answer that question also by means of lemon fruit measurements. Another section of the same grove was used. Eight rows of trees were irrigated regularly every 30 days; eight rows were allowed to dry to the wilting coefficient well beyond the tree skirts, but not in the furrow centers; eight rows were irrigated "normally", that is, according to our best judgment. One set of lemon fruits was measured from July 8 to Nov. 23. Rain terminated the experiment on the latter date. Table No. 2 gives the data obtained.

TABLE No. 2.—Growth of lemons on trees receiving irrigation (1) normally, (2) every 30 days, (3) when dry.

	Aver. gain in diameter from 6-11 to 11-23						Percent of fruit			
	of all fruits		Ripes		Yellows		on 9-23		on 11-23	
Irrigation	in 16th's	in %	in 16th's	in %	in 16th's	in %	Green	Yellow	Ripe	Yellow
(1) Normal	13.7	67	12.5	60	14.6	73	83	17	45	55
(2) Every 30 days	12.0	58	9.7	46	14.0	70	76	24	46	54
(3) When dry	11.1	52	10.2	47	14.8	73	62	38	80	20

The table shows that the so-called "normal" irrigation produced best lemon fruit growth, and as it is our general observation that fruit growth is an indication of the tree condition we may be warranted in stating that the normal irrigation was also best for tree growth. The measurements of the second or later series of fruits showed the same general result in kind but the differences were not so great. These results question the broad assumption stated at the beginning of this article that it is usually assumed that it is desirable to maintain as nearly as possible an optimum soil moisture condition for citrus tree growth.

The above experiments emphasize the fact that one must not keep one's nose too close to any one factor that concerns citrus tree growth. The trees irrigated every 30 days were not at any time too wet in the usual sense. I think the soil moisture condition would have been called very good at all times. The soil drains well, is medium loam to heavy loam, has a moisture equivalent of about 18 per cent, wilting coefficient of about 11 per cent, and the trees were very vigorous in growth, producing much healthy foliage and a large crop of fruit.

A factor to be kept in mind is the necessity for proper soil aeration; and when a soil is kept in an almost continual state of "optimum" moisture, aeration is not as thorough as when the soil is allowed to dry out more. The soil organisms which do the most good are those that obtain most of their oxygen from the air and proper irrigation and cultivation is probably as important to them as to the orchard trees. We know they are agricultural friends and they probably need coddling as well as the trees.

Nothing has so far been said about irrigation intervals. So far as this ranch is concerned there is no such term. Intervals have varied from 30 to 120 days depending upon factors too numerous and tedious to mention, but the main one being naturally the soil moisture content coupled with the judgment of the person responsible for the irrigation.

Irrigating typical young trees on the Limoneira. Those at the right are 7-year old Valencias, transplanted; and on the left are 3-year old nursery Valencias. The lima beans between the trees help pay the way for young orchards.

Cultural practice has not been mentioned, and no erratic policy is followed in that respect. A soil mulch is established as soon after irrigation as the soil permits, shallow at first and deeper later. We consider a good soil mulch important because we have often noticed that when odd trees or corners of orchards are missed by the cultural tools, these trees do not have as thrifty an appearance as those cultivated, and the soil dries out faster, theories to the contrary notwithstanding. We find that the soil mulch not only conserves the moisture below the mulch, but, judging by our laboratory investigations, the nitrate producing organisms are more active where we have compared deep and well tilled portions of the same grove with adjoining areas not as well tilled.

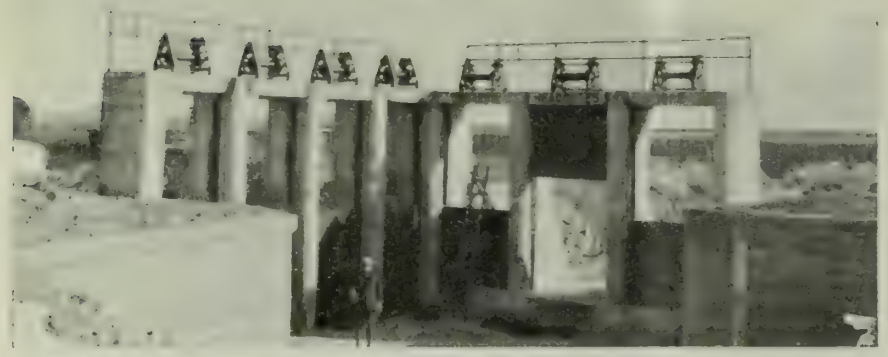
The amount of water to apply in order to bring the soil moisture content up to approximately the moisture equivalent is not difficult to determine theoretically. It is difficult, however, actually to apply a given amount of water to our groves. In some portions of the citrus areas of the state this can be done with some degree of accuracy, because of the physical condition of the soil. The soils in the general area which concern us take water too readily for the best water economy to be practised. While our soils will pack they, nevertheless, take water so readily that it is necessary to rush the water through and change the settings quite soon after the water

(*Continued on Page 33*)

Colonization Succeeds Here Under Government Auspices

From Insolvency to Prosperity via Government Aid

By C. J. BRODERICK



Branch canal headgates on the Lethbridge project, Alberta, Canada. These are no small playthings, as can be seen by comparison of their size with that of the husky farmer lad in the foreground.

THE CANADIAN province of Alberta had a problem on its hands when irrigation water first flowed through the system of the Lethbridge Northern Irrigation District. To a large extent it is indebted to an American irrigationist, Dr. John A. Widtsoe, who pointed the way to its solution. Although the district is not yet "out of the woods" the path is now pretty well defined.

The problem was not one of engineering. Our problem, like most irrigation problems, came after construction. It had nothing to do with operation. It was the age-old problem of human nature that had to be met. During the rush and noise of construction, enthusiasm was keen among the farmers. The reaction came when the first assesment notices went out.

Human Nature Crops Out

The canals and structures were there, the water was already increasing production. The money raised on the bond issue had been spent. Theoretically, repayment should now commence. Everything had worked out well on paper. Why should it not work in practice? Something was wrong.

The system had cost $5,500,000.00 to construct, and the area of the project was 100,000 irrigable acres. Each acre was assessed $5.25, $1.25 of which covered operation and maintenance. The assessment during the first seven years paid the interest and operation costs. After that an additional dollar was to be assessed to retire the bonds in thirty years.

The crux of the matter was that the farmers could not pay $5.25 per acre. Under the law which incorporated the farmers into an irrigation district, lands in arrears of taxes would be forfeited within two years. It is not surprising that the farmers faced the future with concern. They had wanted irrigation, they needed it badly, but they had not counted the cost. It was up to the Provincial Government, which had guaranteed the bonds, to pay if the farmers could not.

Recurrent dry spells had driven these farmers to irrigation. They had prospered in the past during a period of wet years. Substantial homes and communities had been built. On all sides there was an abounding faith in the fertility of the land. Dry years had put them in debt and now with the advent of irrigation each acre had to assume a further obligation of $55.00.

With small holdings of a quarter section or less the assessment might not have been too heavy, but for years this district had been farmed dry in large wheat ranches. Individual holdings ran from 320 to 1280 acres. With irrigation, all land under the ditch was assessed its proportion whether it produced or not. These large farms had to be cut down. Maximum production alone would solve the problem, and new settlers were imperative.

But, if the old settlers could not pay the assessed rate, how could new settlers be expected to pay it? Something had to be done at once if the tax payers of the whole province were not to be saddled with a white elephant.

It was a "Farmers' Government," which had been in power only three years; a "class movement," it was called by old line parties. "Group domination" was another term applied to it. Perhaps it was all of these, but no prejudice was apparent in the way it dealt with this, a purely farmers' problem. No heed was given to the appeal that the province should absorb part of the capital cost by general revenue. Rather —the Government stated—the farmers in the Lethbridge Northern district itself must assume the full payment. An adjustment might possibly be made in the rates, however, until the farmers had had a chance to change over from dry to irrigated methods.

In the United States a similar problem was being studied. A Commission was even then looking into the question and it was being stated that the U. S. Government would have to wipe off many millions as a loss.

An American Comes to Help

On this Commission sat Dr. John A. Widtsoe. He was well known in Alberta irrigation circles. The Alberta Government invited him to consult with it on the problem of the Lethbridge Northern district. He came, and the legislation now known as "The Lethbridge Northern Colonization Act" was the result. It is too early yet to say that the Lethbridge Northern district has its full strength, as a result of Dr. Widtsoe's prescription, but the progress is encouraging, after a year and a half of treatment.

The essence of the legislation lies in the "Home Place" plan. Much idle land in the district was held by absentees. More land was held by resident farmers in excess of what could be profitably farmed under irrigation. Dr. Widtsoe said, "We will establish each *bonafide* the "Home Place" plan. Much idle land a unit commensurate with the farmer's

and Here Private Management Brings Satisfied Customers

Once Shifting Desert Sands Now Intensive Cultivation

By PHILIP B. HASBROUCK

DEVELOPMENT and colonization of unused lands in the arid west has for many years been a subject of great interest not only to the settlers in that part of the country, but to both the state and national governments. Such development and colonization work has been carried on by individual settlers, by co-operative organizations composed of settlers, by outside capital seeking to make a profit from the sale of the lands, and by different government agencies. The various projects undertaken in these ways have not been uniformly successful. Some have succeeded and are now well settled portions of the states and counties in which they are located, containing cities of considerable size; others have been complete failures and have gone back to the original desert condition. Between these two extremes are the great majority occupied by agriculturists who make a better or worse living on their tracts. On some of the federal government projects it has recently been necessary to charge off as losses the payments due the government from the settlers, on the ground that the settlers cannot make a living.

In view of this situation, there is interest for irrigation readers in an account of a development and colonization project which is now almost completed, which has made a very marked success in attracting the right kind of settlers and in locating them on land where they are making a living and a profit.

The life blood of the valley—Lytle Creek. This creek has brought the surface soil which is now Fontana Farms, and today furnishes both water and power.

The Project's Setting

This project is known as Fontana, and is situated in the San Bernardino Valley (California) about eight miles west of the city of San Bernardino. The San Bernardino Valley at this point is some ten miles wide, extending from the Cucamonga Mountains on the north to the Jurupa Hills on the south. The floor of the valley here has been formed by the wash from Lytle Creek which flows out of the mountains from the north, and this wash has taken the form of a cone with the apex at the mouth of Lytle Creek Canyon and the base spread out over the valley almost to the southern boundary. The slope from north to south is not far from 80 feet per mile. The fill in the valley, which has been made by the accumulation of debris from Lytle Creek, is very deep, and this depth has been explained by the assumption that the country south of the San Andreas fault which runs in a general east and west direction along the base of the San Bernardino and Cucamonga Mountains has been gradually sinking during recent geological times, while the country north of the fault has been gradually rising and has formed the mountain range. As the country south of the fault has settled, the different streams, similar to Lytle Creek, flowing into it from the north have filled it up with debris washed out of the mountains, and this process has gone on until the valley fill can be drilled for water to the depth, in many places, of 1000 feet or more, without striking bed rock.

The valley in general, and Fontana in particular, is traversed by three main lines of railroad, and by two main highways. The city of Rialto adjoins the Fontana Tract on the east, Bloomington to the southeast, while the nearest cities to the west are Upland and Ontario.

Poultry raising forms one of the corner stones of livelihood on this project. A view of part of the company's trap-nested stock whose eggs are available to settlers on the property.

Back in the 80's, this entire district was sub-divided by the Semi-Tropic Land & Water Company. The original tract included both Rialto and Bloomington, and a strip of land running up the west side of Lytle Creek to the mouth of the canyon. The western boundary of the tract, which is now the western boundary of Fontana, was six miles west of Bloomington, making the entire tract as originally laid out nine miles from east to west, and ten miles from north to south.

Fourteen or fifteen years ago, when Rialto and Bloomington were well developed cities, and the country around them had been developed into bearing citrus groves and was in a high state of cultivation, the west end of the tract had reverted to the original desert, giving the appearance of being practically irreclaimable. The surface soil consisted of wind driven sand, and would have appeared hopeless as far as development into homesites was concerned, to anyone of less faith and optimism than the founders of the Fontana Tract.

These men believed, however, that the wind could be overcome by windbreak trees, and that the sand, when freed from wind action, could be converted into extremely fertile soil by the use of proper methods of cultivation and fertilizing, and they took over some 16,000 acres of the original Semi-Tropic land and have developed them with the results that can now be seen by anyone passing through on the highways or railroads, for the entire tract is planted and cultivated and is rapidly filling up with high class homes and contented settlers.

The first matter that had to be considered in such a project naturally had to do with water supply, and this was gone into very thoroughly. The water rights and water supply owned and used in Fontana are administered by two mutual irrigation companies, the Fontana Water Company and the Fontana Union Water Company. These are California corporations of the usual mutual irrigation company type.

The original securing of water rights was a long and complicated process, and need not be described here, but the Fontana Companies now own prior rights to both surface and underground flow from Lytle Creek, amply sufficient in wet years to irrigate the entire 16,000 acres in the tract. Together with other users of water from the stream, they practice spreading water during the winter season when there is excess flow of storm water, and thus build up the supply in the underground basins. This spreading is done on waste ground near the apex of the cone described previously in this article, and is the most effective form of conservation that can be practiced. Their deep wells reach these underground basins and thus give them a means for reclaiming the water there contained, late in the season when all the excess runoff has gone by.

In addition to the pumping plants on the underground flow, immediately below the mouth of Lytle Creek, the companies have plants of an even larger capacity in the main tract south of the Santa Fe Railway, some six miles south and four miles west of the creek mouth, which reach an underground storage which, so far, has proved inexhaustible. This source of water is drawn upon in dry years when the creek flow has declined to a point insufficient to meet the requirements of the acreage being irrigated.

All gravity flow from the mouth of Lytle Creek is conducted through a power house owned by the Fontana Power Company, and there furnishes power to operate the wells on the gravel beds in the near vicinity.

The total water supply of the Fontana Companies at present available stands at a minimum of 3300 inches, based on a dry season creek flow of 600 inches, 1300 inches from the upper pumps and 1400 inches from the lower pumps. This is ample for the irrigation of the entire 16,000 acres under the management of the companies, using an average duty of water of one inch to five acres.

The cost of irrigating water will vary from year to year according to whether the gravity supply from Lytle Creek is a large or small proportion of the total supply, as the cost of power for pumping is a large item in cost of operating, and no power is needed to handle the gravity supply. At no time, however, is this cost excessive, and a fair average is $16.00 per acre per year for citrus land, diminishing to as little as $8.00 per acre per year on vineyards.

With future water supply assured, needing only to be developed from time to time to keep pace with additional plantings, the management adopted a policy of planting all its lands to various crops before placing them upon the market. Five thousand acres were planted to citrus fruits, five thousand acres to vineyards, and about 1000 acres to deciduous fruits and olives. In addition to this they have recently set out about six hundred acres of walnuts, and there are also close to thirteen hundred acres of the vineyard lands which have walnuts interplanted with the vines. During this period, when the plantings were being made, the company operated under one management the largest diversified farm in the world.

Reference has been made to the soil, to all appearances consisting almost entirely of wind-driven sand. This was actually the case, and this soil, while very easily worked, was naturally lacking in humus, and required extensive and long continued fertilizing to build up a supply of humus and other plant food necessary for the successful grow-

(*Continued on Page 25*)

Garbage collected at a great many back doors in the city of Los Angeles is carried to this ranch to feed its 35,000 head of hogs, said to comprise the largest hog ranch in the world under one management. Pork raising forms an important part of Fontana's industry.

Program Completed for American Water Works Convention at San Diego Oct. 28-30

Notable Group of Western Authorities Will Read Papers Before Seventh Annual Meeting of Association's California Section; Trips for the Ladies

PLANS are rapidly taking form for the seventh annual convention of the California Section of the American Water Works Association to be held at San Diego, California on the 28, 29 and 30 of October. Paul E. Magerstadt, secretary of the California Section, announces that the program is complete and that a group of papers notable for their scope and practical interest, have been arranged for.

Officers of the association are, C. B. Jackson, Fresno, president; S. B. Morris, Pasadena, vice president; P. Diederich, Glendale, and John Burt, San Rafael, members of the executive committee; and Mr. Magerstadt, secretary.

Water works authorities and others well known to the profession will appear before the convention. The roster of speakers include William Mulholland, chief engineer of the department of Public Service, Los Angeles, who will speak on "The Colorado River Project," and C. G. Gillespie, director of the California State Board of Health, who will present his paper on "Iodine in Drinking Water." "Description of the Impounding Works of the San Diego Water System" will be the topic of a paper to be presented by R. C. Wueste, supervisor of impounding system, San Diego Water Department.

Entertainment Arranged

The entertainment program has practically been completed and special consideration has been given to the ladies in arranging this feature of the convention. Friday morning, October 29, members of the association will be taken in automobiles on an inspection trip to Lower Otay Dam and other points of interest on the San Diego Water System. The City of San Diego will be host at luncheon at the Lower Otay Filter Plant. The party will return to the hotel at 4 o'clock. The ladies will be invited to participate in this excursion.

Special entertainment for the ladies, however, is scheduled for Thursday afternoon and evening as well as on Friday.

A steamer trip on San Diego Bay is being arranged for Thursday afternoon and a theatre party for the evening. Friday, the ladies who do not elect to make the Lower Otay Dam trip will be taken in automobiles on a sightseeing trip through the San Diego parks and to Point Loma.

Friday evening, commencing at 6:30 there will be an informal dinner dance in the banquet room of the San Diego Hotel with the manufacturing interests acting as hosts.

C. B. JACKSON

President of the California Section of the American Water Works Association, who will lead members of the section in the descent on San Diego for the annual meeting, beginning October 28.

The program, in detail follows:

Thursday, October 28

Forenoon, 10:00 A. M.: General Get-together Registration and Review of Exhibits.

Afternoon, 2:00 P. M.: Address of Welcome by Hon. John L. Bacon, Mayor of San Diego.

2:15 P. M.: "Description of the Impounding Works of the San Diego Water System" by R. C. Wueste, Supervisor of Impounding System, San Diego Water Department (Questions).

2:45 P. M.: "The Biological Control of Impounding Reservoirs" by Dr. Carl Wilson, Director of Biological Laboratory, Bureau of Water Works and Supply, City of Los Angeles (Questions).

3:15 P. M.: "Report on Water Meter Maintainance Methods" by J. H. Flagg, District Manager, Pacific Gas and Electric, San Joaquin Division, (Discussion).

4:00 P. M.: Five minute papers and discussions.

Evening, 6:30 P. M.: Informal Dinner, Banquet Room, San Diego Hotel. Business meeting; Report of retiring officers; Report of committees; Election of new officers; Selection of next place of meeting. Address by William Mulholland, chief engineer of the Department of Public Service of Los Angeles on "The Colorado River Project."

Friday, October 29

Forenoon, 10:00 A. M.: "Progress in Electrolytic Chlorination at Sacramento Filtration Plant" by Harry N. Jenks, sanitary engineer, City of Sacramento (Questions).

10:30 A. M.: "Corrosion Problems of a Water Supply System and Methods of Protection" by E. B. Stewart, electrolysis engineer, East Bay Water Company, Oakland (Questions).

11:00 A. M.: "Equitable Charges for Automatic Sprinkler Connections" by Major William Cartwright, automatic sprinkler engineer, National Board of Fire Underwriters (Questions).

11:30 A. M.: Five minute papers and discussions.

Afternoon, 2:00 P. M.: "Underground Waters and Pumping Therefrom" by George W. Trauger, superintendent, Lindsay Strathmore Irrigation District and Edmund K. Barnum, engineer, Fresno City Water Corporation. Presented by Mr. Trauger (Questions).

2:30 P. M.: "The Duty of Water in General Municipal Uses" by Charles Lee, consulting engineer, San Francisco (Questions).

3:00 P. M.: "Iodine in Drinking Water" by C. G. Gillespie, director of state board of health, Bureau of Sanitary Engineering (Questions).

3:30 P. M.: Five minute papers and discussions.

Friday, October 29

Evening, 6:30 P. M.: Dinner Dance, Informal, as guests of the Manufacturers in the banquet room, San Diego Hotel.

Saturday, October 30

Morning, 10:00 A. M.: Leaving San Diego Hotel promptly at 10:00 A.

Vol. II AUGUST, 1926 No. 8

Conceal the Prop

THE other day a friend of ours came to us and said that he had been offered a position of responsibility, with a salary considerably greater than that he was then receiving, by a recently established concern in which he had considerable confidence. On the other hand, he likes his present work and it pays him a good living. The lure of greater remuneration was pretty strong, but there was just one thing that bothered him about the new job, and that was—whether the concern would weather the storms of the first few months of its existence.

So he had devised a scheme that he intended to put up to his present employer: namely, he would ask for a leave of absence in order that he might try out the new position; and to protect himself, as he thought, he would ask that his present employer take him back into the fold, should this new business fail to succeed or should he, himself, "fall down."

Obviously, this man is entering a new field with the wrong mental attitude and the chances are somewhat against his attaining any considerable measure of success, because, always in the back of his mind will be the thought that if the new job does not turn out well he can go back to the old one.

While the cases are not, exactly, analagous, the plan of our ingenious friend calls to mind the basis on which land settlement is conducted in this country and the impetus it gives to failure because of the plan of financing which makes it possible for the settler to lean on Uncle Sam for help when his bank account runs low. One of the basic characteristics which makes for man's success is self-reliance, and this system, like the plan of our friend referred to above, does not make for a self-reliant worker. A speaker at the recent annual meeting of the Washington Irrigation Institute expressed the situation aptly when he said, "If you hold before men constantly the spoon of public aid, they will always want to eat from it; and in so doing, you will undermine the self-reliance of the people with whom you deal."

GRANTING that it is wrong to give aid to the settler in a way that will undermine his self-reliance, what can be done to give aid where it is needed without destroying this all-essential requisite to man's success? The same speaker referred to in a foregoing sentence suggested that provision be made that only self-reliant, sturdy men and women be given the right to settle on government projects. Some defects could be found in this plan, and in particular it might be said that even were there some mode of determining who should and who should not be permitted to settle, the present system of government aid might easily destroy the quality of self-reliance which a man possessed on taking up the task of making his living from the soil.

Government aid has been necessary; and there have been many worthy cases where well-equipped, intelligent farmers have suffered losses due to crop failures, poor markets and other unforseen conditions. So really, government aid should not be condemned, as a blanket proposition, but rather the method by which it is administered.

Someone has suggested that direct relationship should not exist between the settler and the government in financial dealings; that such transactions should be made through a third party, preferably a private banking organization of some sort. We do not propose to suggest any plan that would, on the face of it, have the ear-marks of a workable scheme, but we do believe that any system which would make it more difficult for the settler to obtain direct aid from the government, thereby increasing his self-reliance, would be a good step in the direction of more successful land settlement. There has, undoubtedly, been a too general and perhaps prejudiced method in working out the government's relief program, and this, because of its psychological effect on the settler, may have been a prominent contributory factor in the distress manifested on certain western projects in the last few years.

Any system which will *compel* the settler to hew his own way, by making it more difficult for him to secure aid, would be a move in

POINT *Of* VIEW

the right direction. The government should bear in mind this one thought in dealing with the settlers; that is, if there is anything that makes a man a man, it is his ability to stand alone, on his own merits, without a prop to fall back on in case the going gets a little tough.

The "Waterworks" Issue

THE October number of MODERN IRRIGATION will be the *first annual water works issue.* But it will be more than a waterworks issue.

While containing the usual variety of editorial material, touching upon hydraulic and irrigation subjects of every sort, it will place especial emphasis upon the important problems of domestic and industrial water supply and upon the peculiar relationship which—in the west, at least—these matters bear to the whole field of irrigation, reclamation, drainage, flood control, and allied activities.

IT WILL, moreover, be an Annual Convention Number; since it will commemorate the annual convention of the American Water Works Association, California Section, which will be held during October at San Diego, California, attended by waterworks men from the National headquarters of the organization and from other parts of the West. It will, therefore, contain a full resume of western waterworks activities, progress reports, technical papers, etc., covering the entire preceding year. Much statistical and engineering data, of permanent reference value, will be included, as well as portraits of the officers of the California Section and other leaders of the waterworks industry in the West.

As this will be the one big opportunity of the year for the waterworks supply firms, who will publish their announcements in the advertising columns of the Waterworks Number, the issue bids fair to be a fairly complete "Who's Who" of both the waterworks industry proper and its allied equipment and supply industry. Many reservations for space have been made, already, and others are coming in daily. In one sense, the October issue will be a "waterworks convention" itself—on paper.

But it will be more than an annual waterworks issue and more than a Convention Number. For in this issue will be included the first publication of "Western Waterworks," the new journal of the waterworks industry of the western states; a magazine within a magazine, in short, but published as a special supplement to MODERN IRRIGATION.

WESTERN WATERWORKS is the logical answer to a need, long felt, for a strictly *Western* publication of the waterworks industry.

Because the western water companies, as well as city water bureaus and departments, are operating under conditions peculiar to the West; and because, as the magazine of all applied hydraulics, MODERN IRRIGATION is concerned directly with the same problems of water development and conservation that affect western municipalities, irrigation systems, and hydraulic enterprises of every kind, it is most fitting that this magazine should carry a section expressly devoted to the problems and activities of this important allied field.

The idea of a "magazine within a magazine" is not new. Its practical application, however, is dependent wholly upon conditions which, in the case of MODERN IRRIGATION, are quite unique. The combination is, indeed, ideal, since it results in a larger and stronger publication for all of its readers, having a general appeal to everyone interested in water matters and a still stronger specific appeal to those who are concerned, more directly, in the practical problems of domestic and industrial water supply.

Many advertisers, too, are thus enabled to obtain direct coverage of a most important market not heretofore served by any medium; while still others, selling the general hydraulic field, are able to kill two birds with a single stone. From the standpoint of practical publishing, therefore, as well as from that of practical advertising, the idea is exceptionally sound and already has met with a hearty acceptance upon the part of readers and advertisers alike.

Is It Worth It?

REPORTS emanating from Washington, state that the Secretary of the Interior has found, on a recent trip of inspection of reclamation projects, that revision of policies dealing with Federal reclamation have brought an era of good feeling and prosperity throughout the west.

We are told that this "era of good feeling" has been brought about by legislation adjusting payment of Federal projects and that over $14,000,000 has been charged off from the different projects for unproductive land as a definite loss. Reading further, we find that another $13,000,000 has been suspended as a probable loss. This, we are told, has produced a new spirit of confidence among the settlers, who have again entered into the cultivation of their farms with renewed vigor.

It is good to have this new "era of good feeling" on certain western reclamation projects, but the fact must not be lost sight of that somebody must pay these losses of $14,000,000 and $13,000,000, and ostensibly the loser is the government, which is just another way of saying the 115,000,000 people in these United States. The question resolves itself into whether it is worth $27,000,000 in this particular instance to the people of this country to put the settlers on crippled reclamation projects on their feet. We hope that it is worth while, because $27,000,000 is a good deal of money and the settlers are going to have to do some tall hustling to justify its expenditure on their behalf. After all, the mental attitude of the farmer is what is going to count the most in working out this land settlement problem.

Service and Reputation Stressed at W. I. E. A. Bi-monthly Meeting

Irrigation Equipment Men in Banquet-Get-Together Discuss Irrigation and Waterworks Industries; Well Driller Gives Suggestions on Proper Installation of Pumps; Balancing Reservoirs Discussed

By DOUGLAS G. McPHEE

TORQUES, casing, velocities, accelerations, revolutions per minute, and peak demands were *en rapport* with the humorous adventures of Sandy, Pat and Abie, at the banquet which followed the bi-monthly business meeting of the Western Irrigation Equipment Association, at Stockton, California, July 30. Good humor and serious discussions of technical problems affecting irrigation's Service of Supply followed an abundant meal served at the Wolf Hotel at seven in the evening.

About seventy-five equipment men and others interested in the equipment phase of the industry gathered at the table.

J. E. Lundy, manager of the Sterling Pump Works, of Stockton, was chairman in charge of arrangements and served also as a competent master of ceremonies, introducing as the evening's toast-master Professor C. L. White, head of the department of engineering of the College of the Pacific.

After the adventures of sundry comical individuals of Hebrew, Hibernian and Caledonian extraction had been fittingly celebrated in song and story, as the lighter part of the evening's entertainment, the banqueteers turned to more serious concerns, and listened with interest to E. K. Barnum, chief engineer of the Fresno City Water Corporation, whose subject was "Balancing Reservoirs for Meeting Peak Demands," and who supplemented this paper with some practical suggestions for keeping track of pump efficiencies. His contribution to the program was illustrated by lantern slides which presented the results of his studies in graphic form.

C. B. Jackson, president of the California Section of the American Water Works Association, spoke briefly of the interdependence of the water works and irrigation industries, and the mutual interest which each should have in the other. Recounting the monumental progress which pump irrigation has made in the West since the first switch was closed to connect electric power with a device for bringing water from the ground (a ceremony at which he was present in 1899), he forecast still greater progress for the two great pumping industries of the west.

A. K. Flynn, well driller, of Orange Cove, California, representing a class of membership of the Western Irrigation Equipment Association which continually manifests a loyal interest in all of its activities, discussed a major problem in which well drillers and equipment dealers are mutually interested. He spoke without notes, and the following account is not a *verbatim* transcription, but merely a summary of his remarks.

"Well drillers serving the irrigation industry, and to an almost equal extent the manufacturers of and dealers in irrigation equipment, are interested in the advancement of standards and the standardization of practices in well drilling, in an attempt to eliminate the chaotic and unsatisfactory conditions which have prevailed too often in the past.

"The greater part of the troubles of drillers, and a large part of the problems facing equipment men as well, have come from the activities of men, calling themselves competent drillers, who have been without the needful experience, or the required capital, or the ethical honesty, to do good work.

"You men who make and sell pumps have discovered that any good pump, whether turbine or plunger, will last and give satisfactory service for an indefinite time if it is properly installed on a straight hole, on which it does not have to pump large quantities of sand. You have found that when the hole is well drilled, nine times out of ten your pump gives unimpeachable satisfaction, it pumps no sand, your customer is well pleased, and the amount of servicing required is reduced to a minimum. Under such conditions it is possible for you to be assured that the profit made on the sale of the pump is a real profit, which will not be dissipated in continual servicing or delayed collections.

"On the other hand, the same pump, if the well is poorly drilled, will yield results of quite a different kind. Suppose the well has been drilled for fifteen or twenty cents less per foot, and the driller has landed casing in the wrong formation, or has used the wrong sizes of casing for the conditions encountered, your pump will bring out literally carloads of unnecessary sand. You find that it operates satisfactorily for only a few weeks. The farmer, naturally dissatisfied, comes back on the pump dealer for satisfaction. He will not usually go to the well driller, for he has paid the driller for his services, but the pump is being bought on time, and the dealer is the natural object for his complaints.

"In such a case the dealer may lose his entire profit, or he may lose his good reputation in that vicinity, and very often he will lose, or at least injure both.

"The only remedy for such a condition is for the farmer and dealer to insist that only competent drillers be selected for these important tasks. The usual way the farmer goes about such a thing is to interview the driller first, to find out what it will cost to drill the well. Having received this estimate, he goes to the dealer for prices on a pump.

"The dealer should know the drillers who are competent to do the job right, who are honest enough to keep an accurate log of the well and to supply copies of this log to the farmer and the dealer. And the dealer should recommend such men, at the same time pointing out in emphatic fashion the advantages of having the well drilled by able, honest experts.

"If the dealer will do this, he will save himself great loss and the farmer a grave disappointment. And although in some cases the cost of drilling will be higher, the cost of satisfaction will be much less.

"The lessons which have been learned in well drilling have indicated that a well driller, in order to be safe for the dealer to recommend, must have had at last five years of experience, and equipment worth several thousand dollars. The dealer can not afford to entrust his reputation to a man who has less preparation for such work.

"There is a responsibility on the dealer, therefore, to find out who are the men he can safely recommend. He ought to induce these men to associate themselves with the W. I. E. A., for their mutual interest, because in so doing they will benefit themselves, the farmers and the dealers. The purpose of this association is to formulate uniform rules, to give the drillers opportunity to exchange experiences, and to advance better practices of common problems.

Drillers' Problems Come in for Large Share of Discussion at W. I. E. A. Business Meeting

R. R. Van Ness of San Jose Heads Committee That Hopes to Bring Light Out of Darkness on Several Questions; Pumps Data Book Ready Soon; Fletcher Honored

By H. ELLIOTT TAYLOR

WELL drillers and their problems occupied the floor during the greater part of the regular bi-monthly business meeting of the Western Irrigation Equipment Association, held in the Hotel Wolf, Stockton, California, July 30.

Members of the association engaged in this particular field of endeavor have long felt the necessity of concerted action on some of their many problems, and accordingly this first opportunity for them really to get together in some numbers was greated with a good attendance; and once under way, the discussions were spirited and to the point, resulting in the appointment of a committee, headed by R. R. Van Ness of San Jose, veteran driller, who will make specific recommendations for action on questions brought up for consideration.

Lack of Uniformity

Short informal talks by several drillers in attendance indicated that there has been a decided lack of uniformity in classification of drilling equipment, as far as the California State Highway Commission is concerned. And this, combined with broad and varied interpretations of the laws by various county and municipal officials has created a complicated and unsatisfactory situation in many instances where the drillers have come in contact with these lesser officials.

In the matter of licenses, to cite an example: In some localities the drilling rig, if it moves under its own power, as many do, is classed as an automotive vehicle of the same status as a motor truck; and a motor truck license is required. Then again, the rig may be classed as a trailer, requiring also a license, but smaller fee. Or it is possible, and has happened, that it is listed as an implement of husbandry and, as such, may move over the state and county highways tax exempt.

To secure some uniformity of interpretation of the state motor vehicle laws to drilling equipment is the avowed purpose of the drilling interests.

Urge Keeping of Well Logs

Beneath the surface, geological formations and the location and depths of water tables in various localities are both of paramount importance, not only to the drillers, but to the argricultural interests as well. Accordingly, it was urged by several speakers that a plan be devised whereby drillers in any territory would keep an accurate log of the various strata encountered in their well boring operations, and the depth at which water was encountered. While it was pointed out that there is a wide variation in conditions encountered even in a restricted area, it seemed to be the concensus of opinion, that to have data available would be of considerable value to the driller. The feasibility of keeping logs of drilling wells and providing some central clearing house for the information is another one of the knotty problems that confront Mr. Van Ness and his committee.

C. F. ZIMANSKY

Mr. Zimansky is bringing to a close his second year of service as president of the Western Irrigation Equipment Association, progressive trade organization of the equipment men on the Pacific Coast. The annual meeting of the association is scheduled for September 8 at the Sacramento (California) Fair Grounds.

The final question of major importance, as far as the drillers are concerned, was the consideration of the necessity or advisability of devising a uniform drilling contract. It was pointed out that there are a great variety of contracts and agreements now in use, and an attendant amount of misunderstanding on many finished jobs. Speakers indicated that the contract form should provide special compensation where the driller encounters solid rock or boulders. Other conditions and specifications that might be incorporated in any standard form of contract, should one be evolved, are to be investigated by the committee.

Executive Committee Meets

The customary meeting of the executive committee was held in the morning, when affairs of the internal arrangement of the organization were discussed, and plans to be presented to the membership were considered.

One of the outstanding actions taken by the committee was the recommendation of the name of Professor L. J. Fletcher for the second honorary membership in the W. I. E. A. The recommendation received the unanimous and enthusiastic approval of the membership, upon presentation before the afternoon open session.

Professor Fletcher is director of agricultural engineering at the University of California's experimental farms at Davis, and has been closely associated with the W. I. E. A. through his position as head of the California committee on the relation of electricity to agriculture.

Afternoon Session

With President Zimansky in the chair and Secretary Utley calling the roll, the regular afternoon session opened at 2:30 with about thirty-five members present.

Several committee reports were heard. The standard form of contract for pumping plant installations will probably be ready for adoption at the next regular meeting, it was reported. A communication was read from the officials of the state fair, in which the pump manufacturers and other distributors of irrigation equipment were urged to participate in this annual event. Efforts of the association notwithstanding, the pump exhibit will be housed in the old tent this year as of yore. But 1927 will, no doubt, see a permanent building con-

(*Continued on Page 53*)

HYDRAULIC ENGINEERING

Dealing with the Practical Problems of the Operating and the Consulting Engineer

Looking at Concrete Pipe Through the Eyes of the Irrigation Engineer

By MILO B. WILLIAMS

Consulting Engineer, California Associated Concrete Pipe Manufacturers

THE first concrete pipe manufactured in California was made by hand-mixing of the materials and was molded in steel forms. The semi-dry materials were tamped into the forms by hand and both the jacket and cores immediately removed. This slow and laborous method had many disadvantages and although miles of hand-mixed and hand-tamped pipe have proved successful under the conditions installed, there was ever present a great many human equations due to the change and fatigue of men, which made it difficult to produce a standardized or uniform product by any one manufacturer or in the industry as a whole.

It is easier to make a good quality, large, rather than a small hand-tamped or air tamped pipe, as coarser materials and reinforcing are used to advantage. Many of our manufacturers still hand-tamp large culvert and irrigation pipe successfully, but use a power mixer on carefully graded materials, of a proper moisture consistency.

The use of concrete pipe for irrigation called for the manufacture of metal irrigation appliances in the way of gates, valves, and tools. This developed irrigation specialty companies, which have perfected power machines for the manufacture of concrete pipe.

Power Machines Described

The power machines now used in California may be divided into two general classes; i. e., the "packer head" type, and the "tamping" type. Both machines produce well-compacted concrete in the walls of the pipe, when the materials are properly graded and mixed with the correct amount of moisture and cement. Both types trowel the inside of the pipe smooth and can build all sizes of pipe from 4 inches to 24 inches in diameter, in 24 to 36 inch lengths. Either tongue-and-grove, or spigot-and bell ends are made. Under proper design of the material-mix, no difficulty is experienced in manufacturing sewer pipe to meet the standard specifications of the American Society for Testing Materials. Double-wall and reinforced pipe can be made on these machines while a few of the machines can be equipped to build up to 36 inch pipe.

Considerable poured concrete pipe is made in California for large sewers, culverts, and water pressure lines. With this method of manufacture, high-carbon steel cages or rings can be used for re-inforcing and a pipe made for pressure heads up to 125 feet. Precast poured sewer pipes up to 102 inches in internal diameters have been built for outfall sewers for the city of Los Angeles.

For High Pressure Duty

The combination of steel and concrete revolutionized the construction of great buildings, and the same combination will ultimately expand the uses of re-inforced concrete pipe into unlimited fields, for the carrying of water under high pressures. I see no more attractive engineering opening than the working-out of adaptable designs, methods of manufacture, and application of concrete pipe to high pressure duty. Costs, carrying capacities, and durability, give concrete pipe many unequalled economic and engineering advantages, and improved methods of maunfacture, together with recent successful control of water surge and water hammer, and the provision for contraction and expansion in high pressure lines, makes certain of an early advancement in these fields.

Hydrostatic pressure in concrete pipe places the walls under a tensile stress. This is an unusual duty for concrete when used in non-re-inforced concrete pipe, as in all other concrete construction engineers place concrete under compression only and introduce sufficient steel to meet the tensile stress. High tensile strengths of 300 to 600 pounds per square inch, and imperviousness in a thin wall, are the two principal qualities sought in concrete pipe, which are also factors indicating good durable materials.

California Manufacturers Organized

Manufacturers of concrete pipe in California caught the vision of standardization, uniformity and quality in 1919, and the California Associated Concrete Pipe Manufacturers came into being with Fred W. Stanley, as secretary-engineer, at its head.

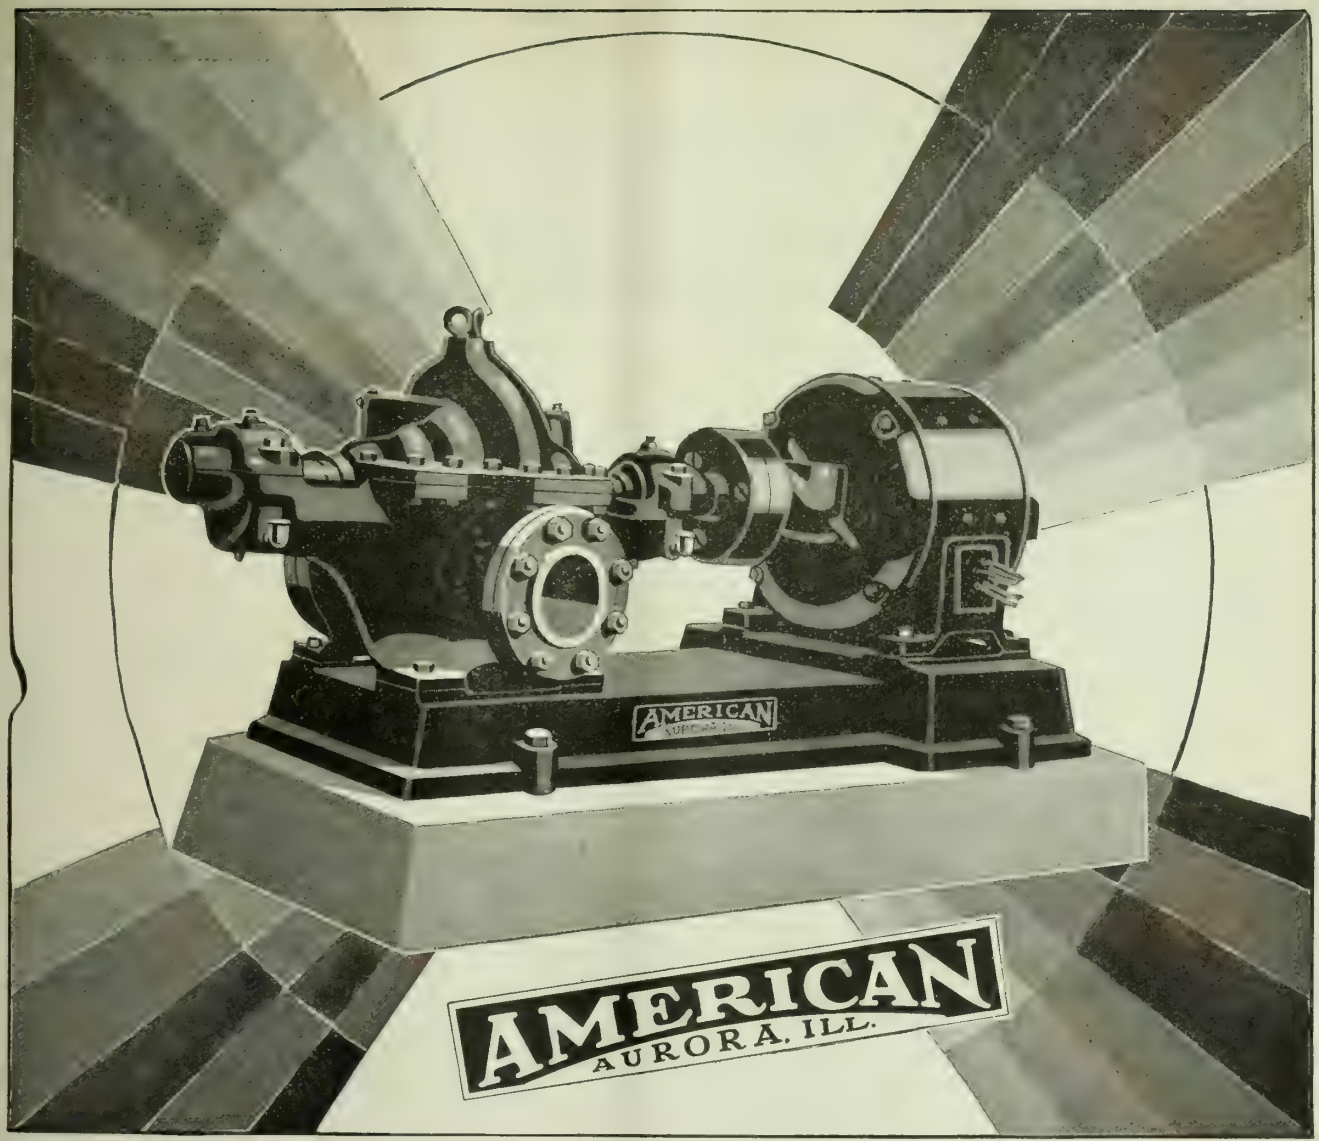
Although Mr. Stanley had become a manufacturer of concrete pipe, the association and the industry lost the hearty support of an engineer of sterling character, who possessed great ability and an intricate knowledge of the fundamentals of concrete pipe design and manufacture, when he met a tragic and untimely death last May.

The California Associated Concrete Pipe Manufacturers has been a going institution since its birth and its duties are to hold a rapidly growing industry in balance. The association is not a price-fixing organization, but a protective, educational and promotional institution.

Engineers' Responsibility

There is only one way for a manufacturer to know the quality of his product, and that is by working to a standardized grading of his materials and continual testing of his pipe.

Engineers can do a great good for the concrete pipe industry, and give a service to the public to the great credit of the engineering profession, by demanding that all concrete pipe installed in their projects not only be made according to association specifications but that the product be continuously tested to see that it is up to the required standards before it goes into the trench. The association will gladly help engineers draw up specifications and assist with testing equipment for the benefit of the industry.



THE "American" type DSMD centrifugal pump is a horizontal split shell, single stage, double suction, centrifugal pump furnished with bronze enclosed impeller, bronze labyrinth wearing rings, bronze shaft sleeves and bronze split glands.

Pump is mounted on extended cast iron base to receive motor and is provided with flexible coupling of the pin and bushing type for direct connection to motor.

Pump is of the double suction type and is built in sizes from 2″ to 42″ and for designed heads up to 250′ depending upon size and capacity.

The bearings of the pump are entirely separate from the stuffing boxes which eliminates the possibility of any grit or water in the bearing. The oil reservoirs in the bearing are large, furnishing an ample supply of oil. The stuffing boxes are water sealed so as to insure tight packing without excessive pressure for friction on the revolving shaft.

THE HYDRAULIC DIGEST

A Monthly Bulletin Board of Brief Facts and Events from Far and Near

Pipe For Golfers

The Pacific Pipe Company, San Francisco, has practically completed the furnishing and installation of the pipe for the Oak Knoll Golf Club, said to be one of the finest on the Pacific Coast, and is about ready to start on two other eighteen hole courses, all using "Pacific" pipe.

Ventura Will Vote On Bonds

The city board of trustees of Ventura, California, recently met and decided to call a bond issue election for $250,000 worth of bonds with which to improve the city's water system. The exact date of the election will be set at the August 9 meeting of the board.

More High Line Canal

A call for bids for the construction of a 10-mile section of the main canal of the Kittitas High Line will be issued next month, it was stated in Yakima recently by Dr. Elwood Mead, commissioner of reclamation, adding that $2,000,000 will be spent on the project this year. The sum of $2,750,000 is available.

Pecos Wins Battle

Pecos, Texas, and the valley beyond, recently celebrated the successful conclusion of fourteen years of fighting to obtain a reservoir which will impound water sufficient to irrigate the 110 miles along the Pecos river. The Pecos Valley Water Users Association has led the complicated battle which ended last month.

No Colorado Weir Yet

The annual construction of the summer weir to halt the low flow of the Colorado river during the dry season may be necessary in the near future, according to advices received from F. H. McIver, secretary of the Imperial Valley Irrigation district. Permission to construct the weirs across the river above Andrade has been granted by the war department in Washington but the district will wait till the necessity arises before the construction is undertaken.

New Main in Glendale

A new thirty-inch cross-town water main in Glendale, California, that had been under construction for the past four months was dedicated late last month, according to Peter Diederich, manager of the public service department of Glendale. It was said that this new main nearly triples the capacity of the city.

Los Angeles to Vote Bonds

On August 31, the city owners of Los Angeles will be handed a separate city ballot on which they will vote on a new 11,000,000 dollar power bond issue and a new 10,000,000 dollar water bond issue. The ten million dollar water bond issue is for the complete purchase of water bearing lands in the Owens River Valley to add to the city's water supply and for new water distributing trunks in the city and for additional storage facilities. The interest and sinking-fund charges on the bonds will be paid from the water-and-power revenues, as required by the latest city charter.

Pima Farms Irrigation Sold

The transfer of the irrigation system of the Pima Farms company to the Catalina Water Company in return for 350,000 shares of the capital stock of the latter comapny was authorized recently by the Arizona corporation commission. At the same time the commission issued an order granting the Catalina Water company a certificate to operate a public water utility for irrigation, and authorizing the sale of $500,000 worth of first mortgage, 7 per cent gold bonds. The authorization of the delivery of 350,000 shares of capital stock of the Catalina company to the Pima Farms was also made.

Imperial Irrigation Damages

Award of 114,000 dollars damages against the Imperial Irrigation District was announced late in July by arbitrators for land fringed by the Salton Sea and near the mouths of the Alamo and New rivers. These lands were injured according to the claims, by excessive flow from the Alamo and New rivers some two or three years ago. By the award, it is said that the Imperial District acquires an easement right to use the land up to 240 foot below sea level contour for drainage proceedings. Out of the 15,000 acres claimed, about one half had been under cultivation and an additional amount was prepared for irrigation at the time o fthe overflow, it was stated by the claimants.

To Build Power Project

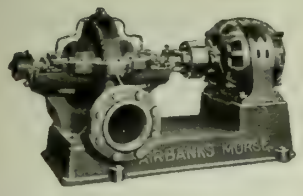
Application for 20,000 acre feet annually from the Tuolumne River and Moccasin creek in Tuolumne county for a power project involving expenditure of approximately $5,574,000 was filed with the State Division of Water Rights by R. V. Meikle, chief engineer of the Turlock irrigation district.

The Turlock district, Meikle's application explains, proposes to build a dam and power plant several miles above the tail water of the Don Pedro dam, from which the ditsrict now draws its irrigation supply.

Diversion of 1200 cubic feet a second is contemplated. A total of 27,000 theoretical horse power is to be generated by means of three turbine water wheels of 9000 horse power each.

Long Beach Improvements

The successful completion of the water development program mapped out for Long Beach, California, by the municipal water department for the coming fiscal year will cost approximately $1,500,000, according to Clark H. Shaw, Long Beach water superintendent. Paramount among the developments to be sponsored will be the development of more new wells in Long Beach proper and in the newly annexed property, especially Virginia City. The construction of more and larger water mains will also be taken into count. It is said that a new storage reservoir will probably be completed that will have a capacity up to 50,000,000 gallons. Mr. Shaw has suggested that a bond issue be floated to carry the expense of the improvements, pointing out the fact that the revenue from the operation will more than care for the interest and sinking fund charges.



Double responsibility

—its meaning to you

When it's a question of pumping service there are always two things to consider—the driven unit and the driving unit. One is dependent upon the other.

Many irrigation farmers who are using F-M pumping equipment were influenced by the fact that they could obtain from Fairbanks-Morse a pumping unit in which both motor and pump were built together and backed by one manufacturer.

In this double responsibility they saw a definite advantage. They need look to but one manufacturer for completely satisfactory service. They had the protection of one definite guaranty, covering not simply pumps, not simply motors—but **water supply.**

While F-M Motor-Pump Units cover a wide range of pumping service, the comprehensive F-M line includes pumps and motors of practically every type for separate installation. We can also furnish Diesel engines in sizes meeting all requirements for power on isolated districts.

An Industry on Desert Sands

(*Continued from Page 16*)

ing of the tree crops already mentioned. Without fertilization, also, the successful raising of crops such as sweet potatoes, peanuts, melons, alfalfa, etc., would have been impossible.

The company, therefore, very early decided to combine animal husbandry with the raising of tree and small crops, and in line with this policy have established their poultry plant, which is one of the largest and most successful in the State, and under the name of the Southern Livestock Company have established and are now operating what is probably the largest hog ranch under one management in the world. The fertilizer from these plants, and also from the barns at the numerous camps where the farm operating force have their headquarters, has all been used in the soil, whose fertility will now compare favorably with any in California, whether developed from naturally fertile soil or built up out of the desert sands.

A brief description of the poultry plant and the policy of the company in encouraging poultry raising on the tract will illustrate the thorough manner in which all of their various operations have been undertaken. It was early realized that citrus culture and poultry raising practiced together on the same land is an almost ideal combination, and that natural advantages existing on this project made an advantageous place in which to practice it. Citrus trees require a large amount of available nitrogen and phosphates for a rapid and productive growth, and poultry manure is ideal for the purpose of supplying this material. The orange trees furnish shade for the poultry and beautiful setting for the residence of the poultry owner.

Poultry Forms Corner Stone

A great deal of attention was given in the early years of the industry on the project to the design of the poultry houses and the appliances to use therein, that would be best adapted to commercial poultry ranches for this climate. As finally evolved these houses all front south, being high in front to admit a good supply of sunlight, and are equipped with movable awnings on the south side to keep out wind and rain. The houses are all built on concrete foundations with concrete floors. The entire arrangement of nests, perches, hoppers, etc., enables the operator to do the greatest amount of work with the smallest amount of labor.

IRRIGATION MANAGEMENT

State Engineer Looks to Colorado River as Added Source of Domestic Water Supply for Southern California

STARTED by the late State Engineer, W. F. Mc Clure, an extended report was recently made by the present State Engineer, Paul Bailey to Governor Friend W. Richardson. The full text of the report, to the California governor on "Water Supply of Southern California," follows:

In assuming the duties of Acting State Engineer under your recent appointment, may I submit to you the first of several progress reports upon the status of current work in this office.

As you know, Southern California contains 20 per cent of the lands of the State that are favorable for human habitation, while but little over 1 per cent of the State's waters are tributary thereto. Although possessing a disproportionately small share of the State's waters, these lands have experienced a rapidity of settlement and improvement that has amazed the entire world. Already one-fifth of the area possessing a water supply lies within the incorporated cities and towns and this fraction is continuously growing larger. The relinquishment of agricultural land for urban use does not reduce the total water consumption, as cities of fairly mature growth use water in amounts about equal to that required for irrigating the same area. The demand for water, therefore, can never grow less in Southern California, but rather, larger supplies will be needed for industries and manufacturies within cities and for the extension of agriculture to the limits of the available lands.

Mono Lake Waters

In arriving at the present great development in Southern California, less than half of the favorable area is occupied by cities or towns and irrigated lands. To reach this stage of development, nearly the entire supply of local water has been brought into use. Since an adequate water supply is requisite to growth, the salvation of Southern California is to seek a distant source of supply. Relief from the pending exhaustion of local waters was temporarily obtained by the importations from Owens Valley by the city of Los Angeles. Some further relief could be obtained by extending this project to include the waters from Mono Lake region, but this would be sufficient to satisfy the growing demands for only a few years. The one supply that can adequately meet the future needs, that is not separated from Southern California by insurmountable physical barriers, is the Colorado River.

The paramount need in Southern California, therefore, is water from the Colorado River. This is vitally necessary for the continued growth and prosperity of the entire south, from Ventura to San Diego and from Los Angeles to the Imperial and Palo Verde valleys. It is of primary importance to the entire State of California that the growth of this wealthy region should never be arrested by the lack of water. Likewise the protection from floods in the Imperial and Palo Verde valleys and other areas along the Colorado is of State-wide concern, for these sections have become important units in the economic structure of the State.

In conformity with your desire for an intelligent and orderly procedure in the solution of all State problems, this office has been engaged for the past twenty months in making the investigations necessary to reach sound conclusions concerning the relation of California to the Colorado River. Not until the city of Los Angeles declared its need for Colorado River water has this river ever been considered as available for lands other than those immediately adjacent to the river itself. The studies by this office of the water resources of the State, however, indicate that there exists a vital need, not alone for the city of Los Angeles, but for the entire southern end of the State. The urban and suburban areas are developing so rapidly that domestic and industrial water will be needed beyond previous conception. Much of this water will be needed for irrigating agricultural lands adjacent to the cities, but the present rapid relinquishment of agricultural lands for occupation by cities and towns indicates an ultimate municipal and domestic use for a very large amount of water, much more than local sources can supply.

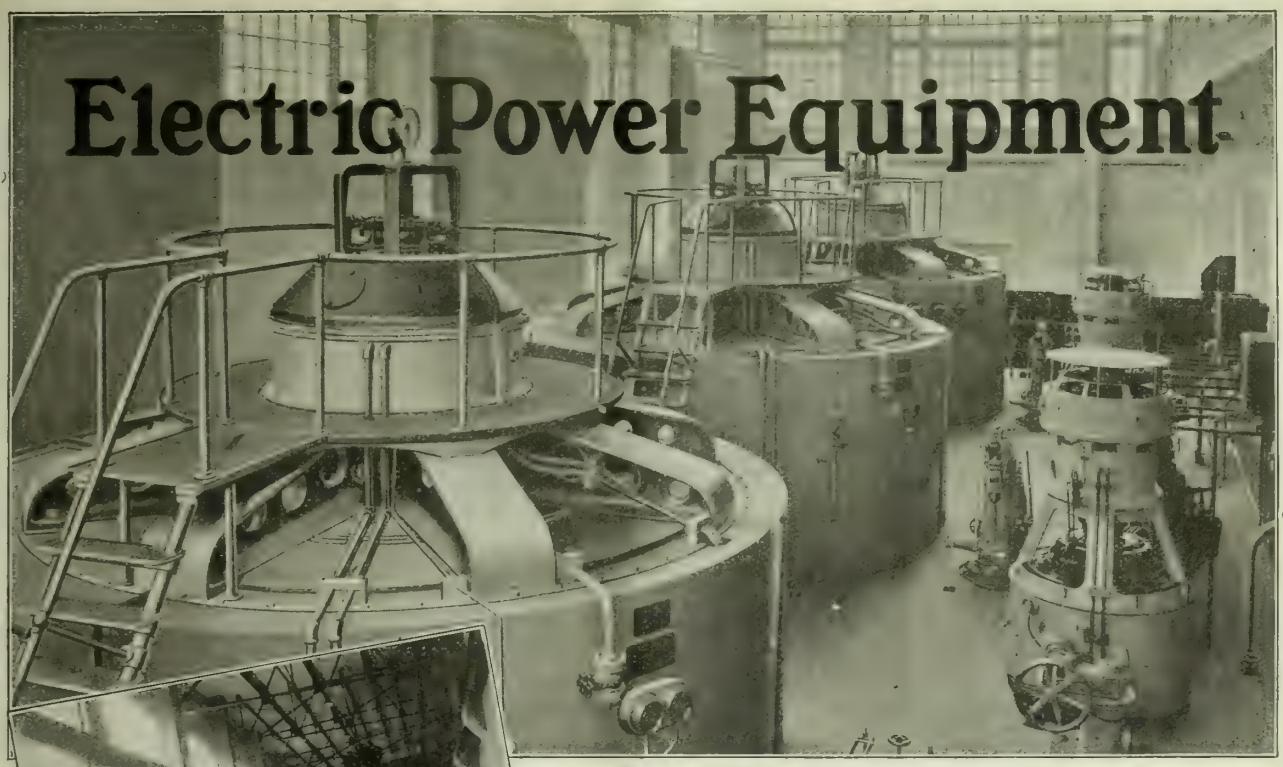
Such a large undertaking as diverting the Colorado River into Southern California can obviously be accomplished by many different plans with widely varying costs, any one of which will cost millions of dollars. It is vitally important, therefore, that the most economic plan be evolved, for otherwise there is danger that the cost will result in stifling tax burdens.

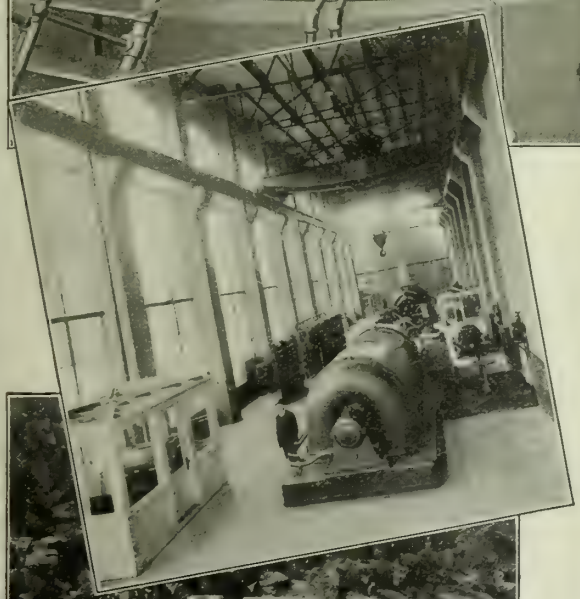
Costly Undertaking

For these reasons, the efforts of this office in preparing a co-ordinated plan for the development of the State's waters as directed by the Legislature of 1925, have been centered upon, first, the determination of the volumes of water required from a distant source for every section of Southern California in order to accomplish the full development of their natural advantages and, second, the determination of the most economic plan for storage of Colorado River water and its diversion to each area. Included in these studies are means for controlling floods on the lower Colorado River and the development of the largest amount of incidental power possible. It is not regarded at the present time that the development of power alone on the Colorado River is of such immediate importance to California as the development of water, for it has been pointed out in the report of Messrs. Butler and Ready to the Los Angeles Chamber of Commerce that the power from the Boulder Canyon Dam could only be absorbed by California markets through the abandonment of other construction programs by the city of Los Angeles and the Southern California power companies. The great immediate value of Colorado River power is limited to the extent that structures, required by the water development program, may be made to do double service by developing incidental power.

The first step in carrying out this program was taken in November, 1924,

Electric Power Equipment





For the power plant, complete equipment "from prime mover to switchboard" is built by the Allis-Chalmers organization. This includes all types of prime movers—steam turbines, hydraulic turbines, steam, gas and oil engines, together with complete electrical equipment. Condensers of all types, pumps, air compressors and many other auxiliaries are also supplied. Allis-Chalmers equipment is used in plants of all sizes, and includes some of the largest power units ever built.

when the writer personally went in the field to investigate possible diversion routes from the Colorado River to all sections of Southern California. The particular effort of this search was to locate a direct route from Boulder Canyon into Southern California, so that the diversion could be made at the elevation of the water surface in the reservoir, the highest possible elevation of diversion, and so that only water desilted by settlement in the reservoir would be taken into the conduit. Such a direct route from Boulder Canyon was found. This route would harmonize with the present proposals for the construction of a dam at Boulder Canyon, now being publicly considered. It would also serve not only the Los Angeles metropolitan area but all sections of Southern California from Ventura to San Diego as well. Since finding this route, the writer has spent a month or more in the field studying these possibilities and directing the efforts of assistant engineers.

Engineers Conduct Investigation

In order to make the work of this office of the highest value to the public, a group of consulting engineers has been associated with these investigations. They are all men so well known in engineering circles that their names are synonomous with knowledge and sound practice, each in his particular line of endeavor. These men are giving their time to the State for a nominal compensation. Their review of the work of this office insures that the plans matured will be the best the engineering profession can produce. The names of these consultants are William Mulholland, J. B. Lippincott, Louis C. Hill, Walter L. Huber, G. A. Elliott, A. J. Cleary, B. A. Etcheverry, F. C. Herrmann and A. Kempkey. Co-operating in this work and meeting with the consulting committee are also Maj. C. S. Ridley, U.S.A., executive officer of the California Debris Commission; Lester S. Ready, Chief Engineer of the State Railroad Commission, and F. E. Bonner, District Engineer of the United States Forest Service and representative of the Federal Power Commission in California. This entire committee has spent nine days in the field studying the Colorado River problems.

Extensive Program Planned

The program of investigations as herein outlined, although it includes only the features of the Colorado River development that pertains to the needs of California, is nevertheless so extensive that its successful completion in time to report to the 1927 Legislature as required by the statute authorizing the work, would not be possible except for the very hearty co-operation of the city of Los Angeles. The water department, under William Mulholland, manager and chief engineer, has extended every aid within its power in making these studies. Its work in preparing plans for an additional water supply for the city of Los Angeles has produced maps of practically the entire area between the city and the Colorado River. All these have been made available to the State without cost.

The investigations and surveys made by the United States Reclamation Service and the United States Geological Survey on the Colorado River provide data on the reservoir and dam sites along all sections of the stream and much information on the water supply.

With this information as a start, the survey for transporting the Colorado River water to the Pacific slope of Southern California has proceeded. A close examination has been made of all the physical features along possible routes. Alternate designs and estimates are being prepared.

Other studies concerning the water supply of Southern California are also under way. A large portion of the present water supply of Southern California is pumped from underground basins. The continual sinking of new wells in recent years has caused a serious lowering of the ground water levels in nearly all sections. This office is now finishing the first complete survey of the underground waters of Southern California. This will show the recession of well levels and the depletion in all the subterranean basins during the last four years.

Also, in co-operation with Orange, Riverside and San Bernardino counties, this office is preparing a plan for the complete conservation and control of the Santa Ana River. As in the Colorado River investigations, the Santa Ana work is proceeding in consultation with engineers particularly well known in Southern California and especially familiar with conditions there. They are J. B. Lipincott, A. L. Sonderegger and G. S. Hinckley.

All this work has been diligently prosecuted through the present biennium along with similar investigations in the remainder of the State, with the end in view of having a report covering the entire subject of the conversation and control of the State's waters completed for presentation to the 1927 Legislature as provided for by statute.

White Signed by Bucks Creek

Ross White, formerly resident engineer, Merced Irrigation district, has accepted the position of resident engineer on construction of the Bucks Creek project of the Feather River Power Company.

Announcement

THE FIRST Annual Waterworks Number of MODERN IRRIGATION will make its appearance as the issue of October, next. This issue will carry, as a separate insert, a new section to be known as WESTERN WATERWORKS, dealing authoritatively with this closely allied hydraulic field in the western territory. WESTERN WATERWORKS will be printed on a sepia tinted paper stock, and will become a regular monthly feature, taking the place of the present department entitled "With the Water Companies."

It will be, actually, a magazine within a magazine—the recognized authority upon all matters having to do with the problems of water conservation and development (as they relate especially to domestic and industrial supply) that are so peculiar to the West: the proper clearing house of current information on western water works activities and a Who's Who of the leading supply companies who sell this important and fast-growing industry.

On to San Diego!

The Annual Convention of the American Water Works Association, California Section, will be held at San Diego on October 28, 29 and 30. The October Number (incorporating WESTERN WATERWORKS) will therefore be a *Convention Special* and will cover the year's activities of the California Section as well as other domestic water developments throughout the western territory. If your company sells the water works industry, as well as the irrigation field, or if you sell the water works industry exclusively, *adequate representation in this issue should be of utmost importance;* since the October Number will be received by every worth while water works executive in the west, and will carry the advertising announcements of every representative company handling water works equipment. It will be kept, for technical reference, long after the convention is over.

Reservations for advertising space are being made NOW. Write, phone or wire at once for rates and full particulars, addressing WESTERN WATERWORKS Dept. of MODERN IRRIGATION.

MODERN Irrigation

WITH THE WATER COMPANIES

Of Interest Expressly to Water Works Engineers, Superintendents and General Managers

The Completion of a Program to Give Water to Two Million People

By DON J. KINSEY

With the Municipal Water Bureau of Los Angeles.

A CONSTANT growth in population and the absence of large water resources near at hand forced Los Angeles twenty years ago to search far afield for additional supplies of this basic necessity of life. The search took engineers for the City to Owens River Valley, and there they found the water so imperatively needed to meet the increasing requirements of their people.

On August 31 the people of Los Angeles will be submitted a water bond issue of $10,000,000 of which $6,000,000 is to be used to carry forward the city's program of purchasing water bearing lands in the Owens Valley. These land purchases, it is explained by William Mulholland, Chief Engineer of the Los Angeles Water Bureau, are necessary to increase and safeguard the Owens River Aqueduct water supply.

Since 1923 the Municipal Water Bureau, of Los Angeles, has been pushing forward its program of water bearing land purchases in Owens Valley. Approximately 80,000 acres are included in the area which either has been or is to be purchased. Of this total acreage, 30,000 acres already have been bought and paid for; 35,000 acres have been purchased and partially paid for, and negotiations for the purchase of the remaining 15,000 acres are now rapidly progressing.

Most of the land being bought by Los Angeles is in the neighborhood of the towns of Bishop and Big Pine, although the purchased area also includes Round Valley, a short distance north of Bishop.

With the city in possession of these lands and the possession of their water rights assured, one of the last steps in the development of this great municipal water project will have been completed, and the Aqueduct will be assured of a water supply sufficient to meet the needs of the people.

As Los Angeles approaches the final stage of development in this gigantic water system, it is interesting to review, for a moment, some of the history and facts in connection with one of the greatest water supply works ever built by an American city.

Owens Valley is situated in the central eastern section of California, its most southerly point being about 200 miles north of Los Angeles. With the Sierra Nevada mountains on the west and the White and Inyo mountains on the east, it is approximately 100 miles in length and varies in width roughly from 5 to 15 miles.

The Valley has a population of about 8,000, including the residents of its four principal towns, Lone Pine, Independence, Big Pine and Bishop.

Down through Owens Valley flows the Owens River, fed by the melting snows of the High Sierras, and finally, unless diverted, it empties into the salt encrusted Owens Lake. It was to secure the life giving water from Owens River that the City of Los Angeles built an aqueduct 250 miles long to tap this source of supply and bring it to the people of this city. The aqueduct was started in 1908 and completed five years later in 1913. Ever since its completion the Owens River Aqueduct has been Los Angeles' main water supply source. Its construction is said to have made possible the present metropolitan proportions of the city; without this water system, it is estimated Los Angeles could never have supported a population of more than 300,000.

Owens Valley

Originally devoted to mining activities, Owens Valley's three principal sources of revenue today are the mountain tourist trade, agriculture, and business growing out of the operation of the aqueduct.

Although the Valley comprises several hundred square miles of territory, only a fraction of the land is used, or ever was used, for agricultural purposes. The greater part of the land is not adaptable to farming either because of the character of the soil or because it cannot be economically irrigated.

For more than twelve years the officials of Los Angeles have been attempting to work out, in Owens Valley, a permanent water policy that would be beneficial not only to the city but to the irrigators of that region.

In 1914 city officials opened negotiations with the irrigators with the view of establishing such a policy. The ranchers asked for time to make certain stream measurements along Owens River. These operations continued until 1921.

In 1921 the city submitted another proposed agreement based on data collected by both the Municipal Water Bureau and the valley ranchers. Under this plan the city offered to construct a 100-foot dam in Owens River Gorge, thus creating a storage reservoir above Owens Valley. This reservoir was designed to be vastly more beneficial to the irrigators in the Valley than to the City of Los Angeles as the city already possessed large aqueduct storage capacity below the ranchers' land.

The majority of the ranchers favored the plan submitted by the city. Others, however, insisted that the city build a dam 150 feet high. The city could not agree to this plan since engineering studies had disclosed that above the 100-foot elevation the walls of the storage basin were so loose and porous in structure that water stored higher than the 100-foot line would be lost through leakage.

When the city started preliminary work on the 100-foot structure the land owners demanding the 150-foot structure instituted injunction proceedings in court, and all the work on the dam was halted.

Thus matters stood until 1923. In that year the southwest was beginning to feel the pinch of a widespread water shortage. Since the ranchers had their

irrigating ditches above the point on the river where water from that source was diverted into the aqueduct, they had, physically, first call on the water. Consequently the shortage in water would be felt first by the city.

In order to assure an adequate water supply for the people of Los Angeles, the Board of Water and Power Commissioners in 1923 authorized the purchase of lands in the valley with water rights on the river.

The Board of Water and Power Commissioners retained the services of three engineers to make a detailed study of the water resources of Owens Valley with the view of determining exactly how much water, on the average, would be available in that region for ranchers and water consumers in Los Angeles. These three engineers were Louis C. Hill, J. B. Lippincott and A. L. Sonderegger.

In December, 1924, the Board authorized the purchase of all water bearing land along the river in Owens Valley. In order to arrive at figures that would be fair to the land owner, the Board authorized the appointment of a special committee of appraisers. This committee was and is composed of three members, namely: George Naylor, chairman of the Inyo County Board of Supervisors; V. L. Jones, Assessor of Inyo County and Grant Clark, former Assessor of Inyo County.

Aqueduct Brings Prosperity

The construction of the Aqueduct is said to have brought many benefits to the Valley. Prior to the initiation of the city's project, the valley was practically cut off from the rest of California by the high Sierra Nevada mountains, on the west and by the Mojave Desert on the south. Its only communication with the outside world, other than a horse stage operating between Mojave and Keeler—a distance of approximately 120 miles, was a narrow guage railroad extending from Keeler northerly through the Valley and connecting with the standard guage line of the Southern Pacific at Mina, Nevada.

In order to transport the large quantities of freight incident to the construction of the Aqueduct, it was necessary that the city should either construct a private railroad into the valley or induce one of the railroad companies to construct a line which would be a common carrier. Negotiations with the different railroad companies resulted in the Southern Pacific Company's entering into a contract with the city to construct a standard guage railroad from Mojave northerly to Owenyo in the Owens Valley, and to carry the city's freight. This line was constructed and gave the Valley a direct outlet to California points, and is said to have done more to bring about the era of prosperity which has existed in the valley since that time than any other one item.

In 1905, at the time of the initiation of the city's project, Inyo County had an assessed value of $2,487,154. For 1925 the assessed value was $11,031,755. In 1900 the population of Inyo County was 4,377. In 1920, it was 7,031. The town of Bishop had not been incorporated in 1900, so that its population was not separately shown in the 1900 census but in 1905 it was estimated to be 740, and in 1920 its population was 1304.

Better Roads Bring Tourists

The city in connection with the construction of the Aqueduct, greatly improved the condition of much of the road leading from Mojave into the Owens Valley. Its activity also served to advertise the Owens Valley, and these factors have resulted in extensive tourist and pleasure-seekers' travel, establishing a tourist business which is said to have contributed greatly to the prosperity of the valley.

The city's operation gave employment to numerous residents of the valley, and the large working forces maintained there by Los Angeles have contributed to the prosperity of the merchants. The city itself has followed the policy of purchasing in the valley such materials needed by it as were available there. It also paid liberal prices for such property as it purchased, which resulted in placing in circulation in the valley substantial sums of money. The purchasers of lands and water rights made in the early history of the enterprise amounted to more than a million dollars, much of which was paid to residents of the valley and placed in circulation with resulting benefits to the community as a whole.

City is Largest Taxpayer

At the time of the initiation of the Aqueduct project, the State of California Constitution exempted from taxation all municipally-owned property. The officials of Los Angeles, feeling that justice to the valley required that land which had formerly been taxed should not be withdrawn from taxation, voluntarily paid taxes for several years, the collection of which could not have been enforced by any legal process. Los Angeles was also instrumental in obtaining an amendment to the California State Constitution, legalizing the taxation of its lands in the valley. It has ever since paid taxes on all of its property, at the same rate as paid by residents of the valley, till today it is the largest taxpayer in the county. More than $100,000 are said to have been paid in such taxes in the last fiscal year.

Where Good Judgment Pays

(*Continued from Page 13*)

has reached the ends of the furrows.

This is the condition on the lower lying soils, and those that have been under orchard many years, and is due largely to the character of irrigation water used. The water contains much gypsum and but small amounts of chlorides, and the result is a well flocculated soil which does not seal itself up against water penetration. It is common enough on those soils to apply about 8 to 10 acre-inches when only about half that amount, or less, may be called for.

On the other hand, we have hill soils that are quite different, being composed of a decent enough surface soil, but having a very intractable subsoil which does not take water readily, and when it gets too much it does not drain well, or not at all. Those grove areas are handled quite differently in irrigation, needing much longer time during the run of the water and sometimes needing deep chiseling to enable them to take water readily enough.

Overhead Being Tried

We are experimenting with the overhead system of irrigation but our observations have not yet continued long enough to compare that system thoroughly with the furrow system. Lemon fruit measurements on large Lisbon trees occupying about all the available space in the grove showed that the overhead irrigated trees grew lemons about two packing sizes larger than the adjoining trees furrow irrigated, from April 28 to Oct. 6. A later series of measurements in the same grove showed increased lemon growth of only about one-half packing size larger on the overhead irrigated trees than on the furrow irrigated trees. Similar measurements carried on in another grove irrigated under both systems showed but little difference. Further comparisons will be made.

On the whole, the amount of water applied in the overhead system in the grove with very large trees was about one-half of the amount applied in the furrow system, but this difference is due to the readiness with which the soil takes water; it is practically impossible to get the lower end of the runs wet enough without applying more water than the grove as a whole needs. Under our climatic conditions, at least, it seems that the overhead system may not be very economical of water in the groves with (say) half grown trees, because the whole soil area necessarily gets irrigated whether it needs it or not. In such groves the furrow centers do not need to be irrigated every time the soil area nearer the trees needs water. Our chemical determinations show, of course, a more uniform vertical distribution of the soluble materials in the soil under

1857 E. 15th St. Los Angeles, Calif.

the over-head system. On the whole, considering all the factors involved, we are not yet prepared to express a choice of systems under our soil and climatic conditions.

To sum up briefly our irrigation control method: We do not check up against each irrigation unit by moisture determinations in the laboratory for each irrigation. The time and expense would be quite an item as we have altogether about 102 citrus irrigation units, not counting walnut acreage, and about 500 acres of 2 year old citrus planting. We train ourselves to judge the moisture content in the grove and compare that with the moisture equivalent or the wilting coefficient, and then calculate the approximate amount of water necessary to apply to bring the dry soil area up to its moisture holding capacity. On some of the soil types a given amount of water can be quite closely approximated; on others, not.

Considerable interference among the various field operations occurs and it must be decided what operation should have the right of way. We do not put orchard tools into the groves, for instance, nor irrigate, just previous to picking if we can avoid doing so, as not only is the fruit knocked off but bruised fruit is undesirable in the packing house on account of decay, and a newly irrigated grove soil would be considerably packed by the pickers. Spraying for the control of brown rot often interferes with irrigation also. Because of so many factors involved in the smooth working of each department we have no established policy except to carry out each operation with as little interference as possible, and hence each superintendent and each foreman must respect the operations of the others.

San Diego Wants Water

The most recent step in the direction of San Diego, California, toward water development was made late last month when the city council passed a resolution decreeing the necessity of a $2,000,000 bond issue for water development in the Sutherland and San Vicente regions. According to city manager, F. A. Rhodes, Arthur P. Davis, a consulting engineer of Oakland, California, will make a selection of the type of dam to be used in the near future.

Chino to Expand District

The Chino Valley Irrigation District has been authorized to issue $85,000 worth of bonds for improvement work according to word from John W. Murphy, secretary of the district's board. Most of this is to be spent in the erection of a dam for further storage facilities that will assure the irrigation of an additional 2,538 acres of land.

An Industry On Desert Sands

(Continued from Page 24)

Another feature of the industry that has been given very close attention has been the breeding of a good laying stock; in fact, the laying stock is the vital and all important consideration here. The fundamental basis of a good laying hen are said to be: first, she has been bred for eggs; second, the proper feed is available; third, she has received good and proper care. Today the project's strain of high producing single-comb white Leghorns is known all over the country. The average hen in the United States produces about 82 eggs in one year. On commercial ranches a production of 110 eggs per year hardly pays the cost of production. Here a study of the individual trap nest records on the poultry farm shows a large number with a production of between 175 and 200. A smaller group shows 200 to 240 eggs per hen per year. A few hens have gone over 300 eggs per year.

All settlers on the project who desire to start a poultry plant of their own are given the opportunity to purchase baby chicks from this egg laying strain. After such a buyer has built his poultry plant according to the standard design, and has purchased Fontana white Leghorn baby chicks, he is given advice by the Fontana poultry expert solely for the purpose of keeping the industry up to the high standard which governs the operation of the project poultry plant itself.

Prosperity by Government Aid

(Continued from Page 14)

ability to make produce." The suggestion was that this unit be a quarter section.

The "Home Place" would pay rates on a schedule spread over fifty years. The assessed rate would not be reduced, but during the early developmental years the Government would assist the settler in meeting his assessment, in the following manner:

During the first year in which a Home Place was registered, the farmer is to pay no rates—the Government will advance the full assessment of $5.25 on his behalf. In the second and third years, the farmer will pay the water service charge of $1.25 per acre, while the Government advances $4.00. In the fourth year, the farmer is assumed to have obtained a start and his proportion will be $3.25 while the Government pays $2.00. Each fourth year thereafter the farmer's proportion advances $1.00 until eventually he will be meeting the full assessment. At any time the farmer may pay the full capital cost of $55.00 per acre and receive title to his water-right.

This schedule took care of the actual resident producer within the limits of the area granted for a Home Place, but any surplus land he might have owned had to bear the full assessed rate. The Government had said, "We will give relief, but not blanket relief." The man with more land than he could make produce will not be allowed to speculate with it, or keep it idle at Governmental expense. If he can not pay on his surplus land, then that surplus goes into the Rate Enforcement Return at the end of two years and becomes the property of the Irrigation District for resale to producing settlers.

Absentee owners can not qualify for Home Place privileges except by taking up residence. Naturally it is unprofitable to hold land out of production at $5.25 per acre annually so this land also finds its way into the Rate Enforcement Return.

Colonization Begins

So much for the machinery. What now was to be done to bring new settlers into the district? It was imperative, if the Government was not to lose considerable money, that vacant lands be settled speedily. Settlers are not readily picked up, and six or seven hundred were required urgently.

An important feature of the new Act was the appointment of a manager to administer the act. Having a status mentioned in the act this manager as "a corporation sole," was given wide discretionary powers. His word was to be final in administrative matters. He could buy and sell lands and he had money at his disposal for loaning to new settlers. The success or failure of the entire scheme depended on this manager.

The problem of the Lethbridge Northern district was one that few men would willingly tackle. The appointee would be required to put into effect a piece of legislation that had no precedent. Moreover he had to find seven hundred new settlers and at the same time adjust the affairs of old settlers. James Pike was appointed manager in May, 1925. He had been the manager of a bank and later was put in control of large land interests where colonization was an important feature.

When he entered into control, there was no land available for settlement. Vacant lands were plentiful but none could be touched except with the consent of the individual owners. No settlement policy could function under such conditions. Litigation had for a time upset the confirmation of the rate enforcement return. He proceeded,

You *Name the* Load
We *Make the* Pipe!

SINCE concrete pipe (as made by Bent) came into its own, engineers question no longer its striking advantages for a great variety of uses. *But*—a concrete pipe installation is either a mediocre or an eminently superior job of work, depending upon who fulfilled the contract.

Many trade names have become hall-marks of tradition, that serve as an unerring guide to discriminating buyers. Today the name "BENT" on a joint of Concrete Pipe marks it as a strictly finely made product. The same care and skill is exercised in its manufacture, and in the laying of the line, as though every future contract depended on *that* job meeting the fullest requirements of specifications—*and more.*

Let us give you a "concrete" demonstration of what we mean by "Bent" Service.

TRADE NOTES *of the* MONTH

Officials Distribute Cataloge

The latest valve and fittings catalog combining two older booklets was released from the press last month by Commercial Iron Works. It is said to be a very complete list of price illustrations and other data interesting to persons connected with irrigation.

Claude Welcome of the Sales Department made a trip up through the San Joaquin and Sacramento valleys and back via San Francisco and the coast routes. He called on all the company's dealers introducing the new catalog and new fittings.

A representative stock of the well-known Dayton Coupling is being carried at both the Los Angeles and Fresno offices now, in addition to "Commercial" fittings.

J. A. Beck, Special Sales Representative for "Commercial" Natural Gas and Distillate Engines for almost 20 years, spent an extended vacation visiting his old home in North Dakota. He attended the 50th anniversary of the Custer Massacre of 1876. Mr. Beck was a sergeant in the famous 7th U. S. Cavalry in the early 80's when many officers and men who were with Reno's column on that day were still with the regiment.

Turbine Pumps Installed

What is said to be one of the very deepest of turbine centrifugal pumps is being installed for the Ontario Water Company by the Peerless Pump Company of Los Angeles. This pump has the bottom of the 18-inch pump bowls placed at a depth of 500 feet with suction pipe below. It has a capacity of 125 Miner's inches and will be driven by a 200 H. P. G. E. Motor. Royal V. Ward is the consulting engineer.

A deep turbine pump to deliver the water direct from the well to the top of the hills in one operation is being made in the El Molino district. The pump is being furnished and installed by this company also. It is a 13 Stage 18 inch pump driven by a 200 H. P. Western Engine. 100 Miner's inches will be pumped through two miles of pipe against a total pumping head of about 540 feet.

The Pacific Development Company of Los Angeles, has placed a blanket order for seventeen additional turbine pumps for their orchard and vineyard tract in Romola Valley in Riverside County. These pumps are to be built to fit the requirements of each particular well as it is drilled and tested.

Borrow Pits Drained

In building dikes and levees it is usually necessary to borrow the material for these banks from adjacent territory,

A reproduction of one of the "Calco" Automatic drainage gates used by the Roosevelt Water Conservation Company.

and this results in depressions which are said to be undesirable both from a health and financial standpoint. They form breeding places for mosquitos, and they represent that much tillable land which will not be put to proper use. In levee operations of the Roosevelt Company it was at first decided to allow the borrow pits to remain, as it was thought that the accumulation of water in them would be of little consequence. However, the next few rains showed that something would have to be done immediately as the levees were washed out.

The engineers ordered the ditch banks rebuilt and for the drainage of the pits installed Calco automatic drainage gates attached to corrugated pipe which are effectually keeping the pits free from water and preventing back-flow when the canals are running full.

Pump Booklet Ready

A booklet consisting of five sections on their pumps has been released by the Layne and Bowler Corporation, makers of Layne and Bowler Pumps. The book is said to be artistic and attractive from a make-up point of view as well as instructive and informative in its content. It consists largely of photographs and diagrams.

The first section, "A journey through pumpland," is devoted to the various types and services that this company offers. M. E. Layne, president, gives a personal account of the experience that the company has had in the pump field. The second section, "Heavy duty pump heads," is given over strictly to pumps involving this type of head. Pictures, diagrams, and explanations go to build a description of these pumps and their uses.

The third section, "Top head and type K pump heads," tells of the feature of the more simplified design of pump heads. These pumps provide for direct connection with vertical motors. The fourth section, "Type LFF pump heads," deals with full floating pump heads, a new development of this company. "Construction notes and useful data" is the heading on the fifth section.

Hollydale to Have Water

Proposing to operate a system for the delivery of water for domestic and industrial purposes to a subdivision on the Union Pacific Railway between the cities of Los Angeles and Long Beach, Hollydale Water Company recently applied to the Railroad Commission for authority to issue 1,000 shares of its common capital stock of the par value of $100 each. Of the stock issue 681 shares are to go to the Mercantile Investment Company in payment for the plant and equipment now in use. Most of the balance of the stock issue is to go to the same company and the money received for the stock will be used in development work.

Install Automatic Gate to Control Water Level in Canal

E. W. King, a civil engineer of Yerington, Nevada, has recently installed a Calco automatic radial gate, to act as an automatic spillway, near the intake of the Saroni Canal at Wellington, Nevada. It is shown in the accompanying cut.

This canal diverts water from the West Walker River and carries it into Smith Valley in Lyon County where it is used for irrigation of a portion of the

Automatic radial gate installation on Saroni

lands lying in the Walker River Irrigation District.

The flow in the West Walker River fluctuates considerably during each day, but the automatic gate is able to control the water level in the canal to a few hundredths of a foot. The capacity of the canal is 120 second feet. The installation of this gate has done away with the necessity of a watchman at the headgates.

Appoint Exhibits Committee for Water Works Meeting

The following committee has been appointed by the California Section of the American Water Works Association to arrange for manufacturers' exhibits at the Annual Convention in San Diego, October 28, 29 and 30.

R. W. Martindale, Pacific Coast Mgr., United States Cast Iron Pipe Co., Los Angeles, Calif. H. M. Dudley, Western Sales Mgr., McWane Cast Iron Pipe Co., Los Angeles, Calif. Frank M. Brooks, Mgr., Art Concrete Works, Pasadena, Calif. George H. Bailey, Pacific Coast Mgr., National Meter Co., San Francisco, Calif. J. R. Barker, Pacific Coast Mgr., Neptune Meter Co., San Francisco, Calif. (Chairman.)

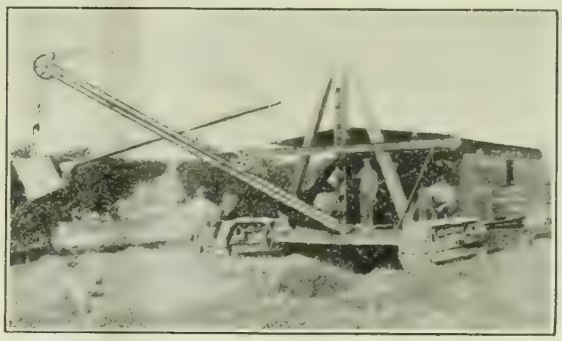
It is the intention of the committtee to carry on the work of previous committees at these yearly conventions. All of the exhibits must be in place at the American Legion Hall, San Diego, by the evening of October 27, Chairman Barker states. There will be ample space for those who have exhibited heretofore, and the committee would like to have additional exhibitors. There will be no charge for exhibit space.

On Friday night, October 29, a dinner and dance with entertainment will be given the Water Works people and their wives, the expense to be divided equally between the exhibitors.

For Cleanout -- Maintenance -- New Ditches

There's a Bay City for Every Job

BAY CITY Land Dredges span the ditch, can dig any desired slope, and dump waste on both banks. BAY CITIES leave clean, wide berms, and can work up or down streams. One trip over the ditch is enough. The Shovel Type Dipper handles hard material in which other types of buckets cannot make a good showing.



At left—One yard BAY CITY Dredge digging and cleaning ditches in Florida Citrus Groves.

BAY CITY Land Dipper Dredges are built to fit the job. Walking, Crawler, Track or Floating mounting. Easily dismantled, transported and assembled. Capacities ½ to 1½ cubic yards. Oil engine or electric operation.

FOR SMALLER DITCHES — OR PIPE LINE TRENCHES

The BAY CITY 16-B convertible Excavator will handle a wide range of work. Operates Dragline, Trench Shovel, Clamshell or Skimmer. All steel. Shipped assembled. Digs any width or depth up to 20 feet.

¾-yd. capacity

STEEL CONSTRUCTION

FULL CRAWLER MOUNTING

or—Model 4 Excavator

BAY CITY Model 4 is a small low-priced convertible, one-man operated Excavator. Fills the gap between hand labor and high priced equipment. Capacity 20 to 40 cubic yards per hour. Gasoline or electric power. A Real Digger economically designed for the small job. Also operates shovel, and clamshell.

RECLAMATION

Let the Engineer and Farmer Each Do His Share on New Irrigation Projects

By DR. ELWOOD MEAD*

CONGRESS in 1926 made appropriations for additional irrigation works which will provide water to irrigate 350,000 acres of land, at an average cost of about $120.00 an acre, for the works. The land to be reclaimed is unleveled, uncleared sagebrush. When canals have been completed, if no change is made in the land, in the interval, everything needed to convert deserts into farms will remain to be done. There can be no income to pay the expenses of operating and maintaining these canals, much less begin repayment of their cost, until settlers are on the land and the farms are made ready for crops. We have in the past built canals without regard to what was to follow their completion, in the careless and unthinking belief that agriculture would come automatically. We accepted as sound the assumption that money and direction were a necessity in building canals, but left the farms, like Topsy, to grow.

Misconceptions Prove Costly

Anyone who studies the report of the Fact Finding Commission, or the reports on the engineering, agricultural and economic feasibility of the proposed new projects, which came as its sequel, will realize how costly to the Government has been our misconception of this matter and how much injury it has wrought to the industrious, but over-confident settler and his family.

If we go farther afield and study the elaborate reports made in connection with the land settlement policies of European countries like Denmark and Germany, or the investigations which preceded the provision of $170,000,000 to finance farm development on irrigated areas in Australia, we begin to realize that here is a fruitful field of rural planning, which constitutes in many ways the greatest agrarian advance of the century and which has been almost entirely ignored and neglected in this country.

These researches have shown what was needed to create a farm, what incomes could be expected from them, what kind of crop marketing and business organizations ought to be created to enable rural communities to function as other business undertakings now function.

Australia Findings

At the end of a most exhaustive inquiry into the costs of irrigated land settlements, Australia decided that it would require an average investment of $6,000 to complete the development of a 20-acre fruit farm, and $10,000 to complete the development of an 80-acre dairy farm. It decided that settlers to be safe risks must provide a part of this development money, and this capital has been fixed at from $1,500 to $2,500; that a provision from some source for advancing from $3,000 to $3,500 to supplement the settlers capital and enable the farm to be made a going concern, must be made. The amount of settlers' capital, and the amount of Government advances vary in different countries, but in all where land settlement has become science, both are provided and all contain these provisions:

1. Amortized payments.
2. A low rate of interest, varying in different countries from 2½ to 5 per cent.
3. From 20 to 90 years in which to repay the advances.

It is because this country has done none of these things that we have reclamation projects with great latent advantages and resources which have been operated from ten to fifteen years at a heavy loss to the Government because from one-half to two-thirds of the land is still unirrigated and untilled. On every one of the projects where these conditions exist, the Government has already lost in operating expenses which can never be recovered, more than would have been needed to inaugurate and carry out a land settlement policy similar to that of Australia or Denmark.

If the experiment provided for in the bill introduced by Senator Kendrick, in the Senate, had been approved, it would have furnished an education in how rural communities can be created, that would have influenced rural development throughout this nation. If we had provided at the outset a land settlement plan like those of other irrigated countries, we would, on one-third of our reclamation projects have hundreds of farms and prosperous homes where we now have abandoned farms and untilled fields. We would doubtless have lost some money, but not one-tenth of what has been lost.

Leveling Not Part of Farming

The economic report, above mentioned, shows what it costs to change unleveled land into farms. The cost is an unquestioned fact, but we have sought to enable this expense to be overcome and to be met by deference of charges, but this expedient ignores the fact that the money required to make the farm a going concern must be spent before the settler can earn a living, let alone make payments for water.

We have also ignored another economic factor. Preparation of land for irrigation is not farming. On the contrary, it is an engineering operation. The implements used are strange and new to the cultivator from humid sections. Their cost is more than the beginning farmer can afford to pay. Leaving this preparatory work to the unaided and uncoordinated efforts of beginners, wastes the time and a large part of the settler's meagre capital. Not all men can level land. It requires a peculiar knack.

*This article is an excerpt from the paper presented by Dr. Mead, Commissioner of Reclamation, before the annual convention of American Society of Agricultural Engineers, Lake Tahoe, California, June 1926. This excerpt was arranged through the cooperation of W. W. McLaughlin, associate chief, Division of Agricultural Engineering.

The experiences which untrained beginners go through under our lack of system, are not only hard on the settler and his family, but try the morale of the Government officials who have to look on without being able to give the aid and advice which they realize are both needed.

Preparing land for irrigation is therefore a part of construction and ought to be so regarded. Every argument in favor of the Government building canals supports a definite program for preparing the land for irrigation with aid from some source where the settler is unable to do it alone. A carefully thought-out program for making farms ready for cultivation would attract more and better farmers to new projects. They could begin doing the things they understand. They would be earning a living almost at the outset. Now they have to risk their time and money in doing work of which they know nothing and which only experts can do well. It results in enormous waste of time, money, and effort.

Recognized by Private Projects

Private enterprise is learning this. At Montague, California, Dr. G. W. Dwinnell, a leader in reclamation planning, after he had completed the irrigation works, mortgaged the land for money with which to make the farms under them ready for settlers. He leveled the land, seeded part to alfalfa, and hired a few good carpenters to build houses and barns. He did this at far less outlay than it would have cost settlers. He bought carload lots of high grade Holstein cows which he sold to settlers at cost on time payments.

The plan sold the farms. Settlers could start with an income in sight which is a wonderful aid to courage and confidence. The scheme has been a financial success. Not a single settler has failed and Dr. Dwinnell has not had to worry over unsold land or delinquent payments.

At Los Molinos, California, unimproved farms were sold to settlers without any inquiry as to their capital or plan as to what they were to do. Long before development was completed, their money was gone, and they faced disaster. It happened that Frank Vanderlip was a stockholder in the project. He went down in his pocket for a quarter of a million dollars; loaned it to these settlers, and by so doing saved their homes. Without help at this time, Los Molinos would have been a social tragedy. Credit made it one the most prosperous colonies in northern California.

Los Molinos is a near neighbor to Durham, one of the two California State land settlements. At Durham the money

used in preparing the land for irrigation and seeding it to alfalfa was obtained from the Federal Land Bank. Settlers have 34½ years in which to repay this cost. Payments are amortized. A yearly payment of 6½ per cent keeps up interest and pays off the debt. If these settlers had had to pay 8 per cent interest on money borrowed to prepare their land for alfalfa, or pay off the loan in ten years, nine out of ten would have failed. If they had been left to level and seed the land without aid or direction, Durham would have been a fiasco. As it is, it has an international reputation as an example of success in rural planning, and in showing how poor men can be helped to become farm owners.

WISCONSIN CO-OPERATES

Wisconsin has co-operated with private colonies in securing funds to build houses, clear land for settlers for the cutover areas of that State. Mr. Hugh MacRae of Wilmington, North Carolina, has blazed a trail in scientific land settlement that is well worthy of study by all students of the problem of how to attract and hold people on the land. The basis of his system is to have development work completed before the settler comes on the land. The farm is a going concern, is sold on long time payments, and the settler is given expert advice regarding his crop program.

Prosperity By Government Aid

(Continued from Page 35)

however, to register resident farmers for their Home Place units, a task that was fraught with many difficulties. From each applicant for Home Place a statement of the man's affairs had to be taken and an attempt made to adjust his debts to a point where the farmer would have a chance to make good.

In the meantime, the larger problem of colonization was never lost sight of. Where, at first, it was a moot question whether settlers could be obtained, the problem now began to solve itself. Attracted by the new water schedule, settlers were actually clamoring for locations. The litigation was still in progress in January, 1926, but it was settled in favor of the District in April. There were, however, two large blocks of land owned by a railway company and a trust company. These concerns realized that eventually their lands would be lost. A deal was made and the manager secured these tracts at a nominal sum. The wide publicity given to the taking over of these lands had a psychological effect on prospective settlers. The terms were easy—no down payment, nothing to pay

the first year, and the prices (less water right) ranged from $10.00 to $15.00 per acre on crop payments. There was literally a rush for land.

Where Did They Come From

Where did these new settlers come from? There is a piece of country known as Southeastern Alberta which in late years has suffered acutely from long continued dry periods. Fifteen or twenty years ago this country was settled by a very fine class of Canadian and American farmers. They practiced what is known as "Bonanza Farming." Wheat ranches of a thousand acres were common and the work was done with tractors. The first years were lucky years. The soil was virgin and fertile. Rains came and fortunes were made from wheat. Then wheat began to take its toll. The fibre disappeared from the soil, and summerfallow was resorted to. The people refused to give up, but rains did not come. Hope gradually gave way to despair and, finally, when the Lethbridge Northern district opened its doors, these men came forward with nothing but their horses and equipment.

What better type of farmer could be desired? The Alberta Government killed two birds with one stone when it welcomed these men to share in the fruits of irrigation. And how they do appreciate the water! The old hope, the old faith is still there. It was never killed.

Entire Project Moves

Two hundred and fifty new families, equipped and ready to go, have been placed in the Lethbridge Northern district since January 1st., 1926. The roads have been crowded all spring with vehicles of every description bringing in settlers. Whole buildings have been moved, some as far as fifty miles, while others have been broken up and transported as lumber. The Government issued free freight warrants, and new hamlets are springing up throughout the district. The Canadian Pacific Railway which already serves the district with two lines, has recently completed a third. In all, there are nearly 600 families now resident in the district where there were barely 350 in 1924.

In 1924, the Lethbridge Northern crop census showed a production of $500,000.00. In 1925, the production increased to $1,300,000.00. The new acreage under crop this year promises a production of $2,000,000.00, and there is still room for three or four hundred new families.

WHO'S *WHO* AND WHO'S *WHERE*

IN THE WORLD OF HYDRAULICS

Personal Notes and Impersonal Observations About Men You Know

D. W. Murphy, prominent consulting engineer of Los Angeles, spent his vacation in San Francisco, the latter part of July and the early part of August.

A. C. Houghton, of Attalia, Washington, for ten years manager of the Attalia Irrigation District, has recently been appointed the new manager of the West Extension Irrigation district, according to word received from Hermiston, Oregon.

According to the latest advices from Major Olberg, in charge of the construction of the Coolidge dam project in Arizona, bids for the construction works will be called for within the next ninety days. Money has been appropriated for the first work to begin on the dam which will be the first multiple dome type to be built.

Dr. Elwood Mead, Commissioner of Reclamation, has just returned to Washington from an inspection tour of the western states and the federal projects there. Mr. Mead has submitted his report to the Secretary of the Interior, and has stated that the morale of the farmers on the projects is much higher this year than it has been in the past.

J. B. Brown, extension specialist in irrigation at the University of California, has been conducting tours for overhead enthusiasts during the last month. A study of root distribution, water penetration, methods of application, and the part that cultivation plays in moisture penetration are the subjects that were discussed.

The names of new directors for the Moreno Mutual Irrigation Company, California, have been announced. The directors are Louis H. Didier, president; F. L. Towner, vice president; C. O. Lantz, treasurer; Albert A. James, secretary-manager. George E. Holyoke is chief engineer in charge of construction, and F. E. Trask, of Los Angeles, is the new consulting engineer.

Ralph Criswell, for nine years chairman of the Los Angeles (Calif.) Power and Light Commission, recently addressed a large gathering of Lomita (Calif.) citizens on the merits of a water system for Lomita, and its relation with the city of Los Angeles. He outlined the costs of such a system and compared the present value to the future value of the lands affected.

C. H. Pease, editor and business manager of the "Delta Irrigation News" and a prominent authority on irrigation matters, has just returned to Mc Allen, Texas from a tour of the western states and an inspection of their irrigation projects. Southern Oregon, the Yakima Valley of Washington, Shoshone Project, and North Platte, Wyoming, were among the projects that Mr. Pease visited.

"If the products of all the oil wells of California were permitted to flow undisturbed into the sea the loss would be less than the loss of the precious fluid of the mighty Colorado River that is poured into the Gulf of California," said Friend Richardson, governor of California, in speaking of the Colorado river recently and the importance of harnessing it with the view of preserving its waters and energy for use in the southwest.

Professor Charles F. Shaw, soil technologist for the College of Agriculture, University of California, has recently accepted an invitation from J. Sanchez Mejorada of the Mexican reclamation committee to make a complete survey of the agricultural possibilities of the Santiago district at Aüguas Calientes, Mexico. It is said that this is in preparation to the inauguration of a large irrigation project there.

R. F. Del Valle, president of the Board of Water and Power Commissioners of the city of Los Angeles, has been reelected for the ensuing term. James B. Baker has been elected vice president of the board for the same period. John R. Richards has been appointed to fill the vacancy left on the board by the resignation of C. A. Dykstra, who was recently transferred to the position of efficiency and personnel director of the department.

John H. Mann, of the Commission of Public Utilities of Portland, Oregon, reports that R. V. Meikle, a prominent consulting engineer in the western irrigation field, spent a few days in Portland recently advising the officials of that city as to the feasibility of constructing an immense water reservoir. The reservoir is to be planned for Bear Creek, and it is said that more than 11,000,000,000 gallons of water will be impounded there. Mr. Meikle has been associated with the Exchequer, Don Pedro, (both of California) and the Bear Creek projects.

Albert Givan, chief engineer of the Sacramento (California) municipal utility district, and assistant engineer, E. D. Hayward, headed a party of officials from Sacramento recently that made a trip to Ice House and Union Canyons with the view of considering harnessing streams therefrom for the future water and power supply of the city. It is said that the district is capable of storing 210,000 acre feet of water and developing 91,500 continuous horsepower. It is also said that more than 200,000,000 gallons of water could be delivered to the city for its domestic supply.

Edward I. Kotok, for 15 years an officer of the California district of the United States Forest Service, has been appointed the director of the new forest experiment station to be established in San Francisco, according to an announcement by Col. W. B. Greeley, chief forestor. Mr. Kotok started his service in the Shasta National Forest in 1911 and in 1919 was made fire inspector for all the national forests in California. The other appointments to the new station include Duncan Dunning, silviculturist of the California district; A. E. Wieslander, technical assistant from the Lassen National Forest; and H. A. Higgins, junior forester.

Forest Fires Take Annual Toll of Millions in Western States

A forest fire that ranged along a six mile front in Tuolumne county, California, has swept away thousands of dollars worth of Hetch Hetchy property, according to press reports early in August. The entire system was threatened for a while, but the fire was finally put under control by 250 fighters from the Pacific Gas and Electric and the Hetch Hetchy companies. The Early intake unit was put out of commission by virtue of destroyed lines, and a similar fate was feared for a while for the Modesto Creek unit.

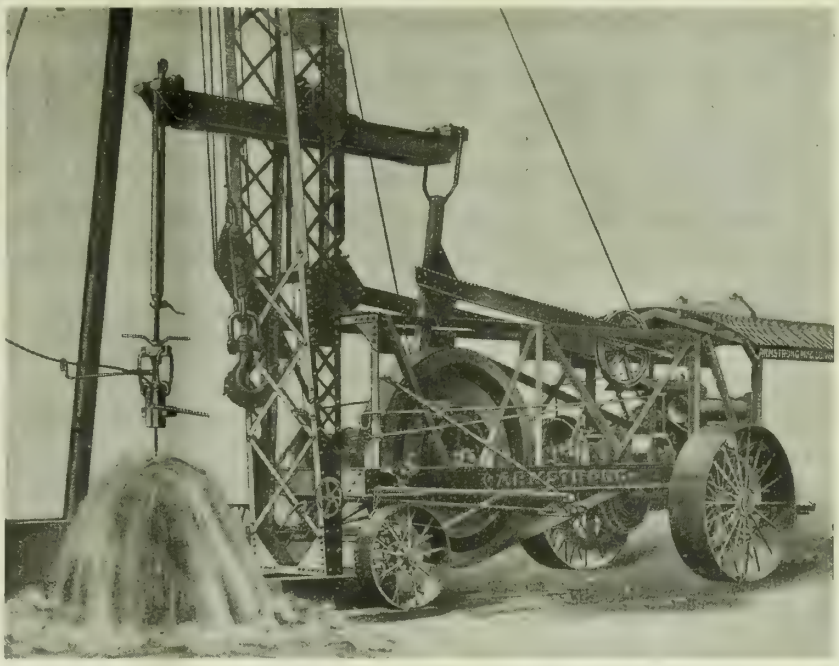
Other fires this season have destroyed much property and laid barren vast water sheds, according to official figures given out from federal and state authorities in Denver, Colorado. It is reported that approximately 600,000 acres have been burned over and that property losses have amounted to several million dollars.

It is stated that California is the heaviest sufferer, with 219,000 acres of national forests and adjoining lands devastated. Between 6,000 and 8,000 men are still employed by the federal and state governments in California to stem the fires that have proved the most serious in a decade. Over 4,000 men have been employed by the governments in Washington, Oregon, Idaho, British Columbia, and Montana. The following is the officially estimated data on the destruction rendered by specific fires:

Kaniksu National Forest, 2500 acres burned over; Pend Oreille, 14,000; Couer d'Alene; 15,000 acres in Stevens county, Washington; 24,000 acres in the Chelan and Colvin National forests of Washington; 50,000 acres in the Cascade Range in Southern Oregon; 11,000 acres between the Columbia River and Eugene, Or., between 20,000 and 30,000 acres of slashings and logged-off land; Crater National Forest in California, 3600 acres.

Earl C. Pound, president of the Imperial Irrigation District, has returned to the Imperial Valley after having spent several days in Los Angeles, in conference with the Boulder Dam Committee of the Los Angeles Chamber of Commerce. The committee will meet again in the near future, it is reported, to act on the feasibility of petitioning congress to appropriate a million dollars for levee construction work along the river in Mexico.

The offices of J. R. Mason and Company, San Francisco, California, have announced the purchase of $500,000 worth of bonds issued by the Mohawk Irrigation district. The issue was unanimously approved by the voting landowners last February. The sale was made by the district's directorate.



The Armstrong All-Steel Drill

"Built for Service Since 1867"

THE frame and derrick of the ARMSTRONG DRILL are all steel. The main sills of the frame are steel channel. The upper part is made of steel angle bars, with braces and trusses all hot riveted in place. There are no nuts, screws, nor bolts to get loose or drop out. There is nothing about it to rot, rust, check, crack, break or wear out. It is as rigid as the skeleton of a sky scraper—as strong as a steel bridge—built to last an age. It cannot warp, spring nor twist out of shape, and always holds the shafting and bearing in perfect alignment. It has been designed and built for maximum strength and long life.

LEGAL *and* JUDICIAL

A DEPARTMENT CONDUCTED BY HANKINS & HANKINS

Water Rights in Utah

A Party Having Been Adjuged the Owner of Water Cannot be Deprived Thereof Without A Clear Showing of Abandonment

In the case of Torsak v. Rukavina: (Utah: May 11, 1926) 246 Pac. 367, the defendant set up a former adjudication of water rights as a defense to plaintiffs claim of unlawful interference with his right to the use of certain water.

In supporting the judgment of the trial court in favor of defendant the Supreme Court of Utah says:

"Another answer is that, although the testimony of the plaintiffs witnesses that within the last three or four years immediately preceding the trial of this action the defendant permitted a small quantity of water to flow down a certain creek, or water course, was uncontradicted, yet, in view of the finding upon the plea of res adjudicata, that had no effect, and could have none, upon what its findings and judgment should be. The mere fact that the defendant permitted some water belonging to him by virtue of the former decree to flow down the stream in question would give the plaintiff no right to claim that the water, without alleging and proving that defendant had legally abandoned the right to use the same by not applying it to a beneficial use for a period of seven years or more, or without alleging and proving that he had actually and intentionally abandoned his right to the use of said water."

Damage Suit Plea for Defense in

Act of God As a Defense Should Be Pleaded

In the case of Fort v. Brighton Ditch Co., 246 Pac. 786 (Colo.) April 19, 1926, the Supreme Court intimated that the defense of Act of God in a suit for damages arising through the breaking of a dam caused by heavy rains should be pleaded to be available. In the instant case proof was insufficient to support the plea so the question was not directly decided.

What Constitutes Title by Prescription?

In order to obtain title by prescription to water the use must be open, notorious, continuous and under claim and color of right.

In the case of "in re Water Rights in Ahtanum Creek and State v. Achepohl et al," 245 Pac. Rep. 758, the Supreme Court of Washington held: "Adverse use of water for statutory period must be open, notorious, continuous, and under claim and color of right, and any act done by other parties claiming water that operates as an interruption, however slight, prevents acquistion by adverse right."

The court further held "Claimants' right to use water of the creek is not established by estoppel, where the use thereof was in violation of a court decree, and other users along the creek always objected to such diversion."

State Labor Law Not Applicable to Irrigation

Attorney General U. S. Webb, Renders Opinion to Labor Commission on the Question of the Application of the Eight Hour Law to Irrigation Districts.

In an opinion under date of July 22, 1926, requested by Walter G. Mathewson, Labor Commissioner, U. S. Webb, Attorney General of hte state of California, holds that Article 20, Sec. 17 of the Constitution, wherein it is provided that "The time of service of all laborers . . . employed upon any public works of the State of California . . district . . . or any other political subdivision thereof . . . shall be limited . . to eight hours in any one calendar day . . ." does no apply to Irrigation Districts. That the use of the word "district" in this provision is to be considered as referring to such "districts" as may be considered political subdivisions of the "State". An instance of such district would be a school district which functions politically. Also in support of this position he quotes Section 653c of the Penal Code as follows:

> "Section 653c of the Penal Code was adopted by the Legislature to make effective the constitutional provision. It is to be noted that the legislature in so enacting the penal provision contained in this section eliminates the word "district" as found in the constitution and provides that the time of service of any laborer, workman or mechanic, employed upon any of the public works of the State of California, or of any political subdivision thereof, or upon work done for said state, or any political subdivision thereof" is limited to eight hours during any one calendar day.
>
> The Legislature therefore appears to have considered that the district referred to in the Constitution is such a district as may be considered a political subdivision of the State.

The Attorney General holds that an irrigation district is not a "political subdivision" so as to come within the eight hour law.

In referring to an earlier opinion rendered by his office to the labor commissioner (April 16, 1924) he states that in his opinion Section 10 of the Wage Law, requiring semi-monthly payments, did not apply to Irrigation Districts as the exception including "employees directly employed by any county, city and county, incorporated city or town or other municipal corporation," would include irrigation districts under the term "other municipal corporations". (Citing In re: Madero Irrigation District, 92 Cal. 296), but that situation is not present in the question presented.

Annual Assessments for Bonds

Must An Irrigation District's Annual Assessment Be Sufficient Each Year to Provide For the Payment of All Bond Interest and Principal?

A decision which appears to be somewhat inconsistent with a recent line of authorities from other states is rendered by the Supreme Court of Colorado in the Case of Board of Commissioners v. Heath, 246 Pac. 795 (May 3, 1926).

An irrigation district required a certain sum to pay bond, principal and interest. An assessment was levied in a smaller amount and a Writ of Mandamus is sought in order to require the full levy. The directors of the district answered, setting up, in effect . . . that there were enough outstanding and uncollected taxes of that levy to pay . . . bonds and interest in full . . The Court states: "We must presume, though it is not alleged, that these taxes are collectable. The presumption is that men will perform their duty and pay their lawful taxes. If for any reason these taxes are not collectable, that should be shown by replication, or should otherwise be made to appear in the record . . . The case must be reversed, with directions to discharge the writ, or, if petitioner desires, to take such proceedings as will properly raise and determine the issue whether these taxes are collectable to a sufficient amount to pay the bonds outstanding."

Irrigation Districts Held to Be Corporations

An Irrigation District Acts As a Private Corporation As Respects Ordinary Business Transactions

In the case of State v. Dilworth (April 12, 1926) 246 Pac. 167, the Supreme Court of Montana makes a distinction as to the capacities of an irrigation district, holding as follows:

"An irrigation district is a public corporation (Crow Creek Irr. Dist. v. Crittenden, 227 Pac. 63) and is governed by a board of directors which constitutes its corporation authority, and is charged with the duty of managing and conducting its business affairs. So far as its ordinary business transactions are concerned, they stand upon the same footing as a private individual or the directors of a business corporation similarly situated."

In defining the status of district warrants the court further states: "This order, sometimes designated a warrant, is merely a direction to the custodian to pay the specified sum, and in effect amounts to nothing more than would a bank check upon the district's depository, if its funds were handled in that manner; it is merely a device for properly drawing money from the custodian or depository. There is no statute conferring any special characteristics upon these orders or warrants."

Water Right Held Property Right

Water Rights Under Colorado Law

In the case of Ft. Lyon Canal Co. vs. Rockyford, etc. Co., 246 Pac. 781 (Colo. May 24, 1926) the Supreme Court of Colorado states that it is the settled doctrine of that state that a right to divert water from its natural streams and to use the same for growing crops is a property right; that it is not essential to its continued existance that the water thus diverted be forever used on the particular tract of land to which it was first applied, but its owner may sell it, separate and apart from such land, for use on other lands of the grantee or he may himself change the place of use or point of diversion, so long as the vested rights of other appropriators are not thereby injuriously affected.

No Lien Established by Rice Ditching

The construction of ditches for raising of rice does not give the contractor a right of lien on the land.

In the case of Ogden v. Byington, 71 Cal. Dec. 217 (Feb. 16, 1926) the Supreme Court of California makes a distinction between ditch construction necessary for rice raising as opposed to ditching, leveling, checking and draining necessary for alfalfa growing (Mendoza v. Central Forest Co. 37 Cal. App. 289). The question arose on a suit brought by plaintiff to foreclose a mechanic's lien on the land for work done in the construction of ditches.

In the Mendoza case the trial court found that the work done for alfalfa was of a permanent character and constituted a "structure" within he meaning of Sec. 1183 C. C. P. constituting a permanent and valuable improvement to the land and necessary to its highest and most profitable uses.

In the Ogden case the trial court found that the materials furnished and the work done were solely and only done in the preparation of the land for the cultivation and raising of a crop of rice thereon and that no value was added to the land by reason of the work.

The Supreme Court then states "that the character of the work done and materials and supplies furnished and for which a lien is sought to be established and foreclosed in the instant case (Ogden) was not such in point of structural character or permanency as would bring it either within the provisions of Sec. 1183 or 1191 of the Code of Civil Procedure so as to subject the lands of respondent to any lien predicated upon the performance of the plaintiff's contract with the respondent's tenant and for the collection of any balance claimed to be due from such tenant by virtue thereof."

Text On Hydraulics Out

Supplying the profession with a text book on the technical angle of hydraulics, McGraw-Hill Book Company has recently published Joseph N. Le Conte's "Hydraulics." This book deals with the theory of hydraulics and the principles of hydraulic machinery. The student in this field is here shown how engineering problems can be reasoned out and solved by appeal to first principles. The text, while technical in its trend, is fundamental and basic to the engineer or layman seeking a book dealing with a technical subject in a practical way.

OVERHEAD IRRIGATION

CONDUCTED BY WM. J. B. STEWART

IS NEW PIPE BETTER FOR OVERHEAD THAN OLD?

THERE are several different opinions with regard to many of the practices and materials used in installing overhead irrigation systems but the three major subjects now under discussion are: new or old pipe; wide or short coverage sprinklers; comparative even water distribution and functioning efficiency of various sprinklers.

There are, of course, two sides to these questions to cause them to assume their present prominence. It is only with a view of providing some interesting information to the prospective purchasers of overhead irrigation systems on the matter of old or new pipe that this is written at the present time. With so much improvement work going on in sprinklers the time is hardly opportune for drawing conclusions as to the coverage, distribution and functioning efficiency of various sprinklers.

Duties Summarized

To summarize the duty of pipe, the prospective purchaser should take the following into consideration in considering the relative merits of used and new pipe: The pipe should conduct water under 40 to 60 pounds pressure per square inch with not more than 15 to 20 pounds friction loss from supply to sprinkler risers; there should be little or no loss through leaks in the pipe or through weldings or fittings; the pipe should be capable to perform its duty not for stretches of from 6 to 12 hours at a time, but periodically and continuously; the pipe should be of such metal so manufactured, reconditioned, and protected and so installed either by welding or screw jointing as to reasonably assure from 10 to 15 years or more service from the water distributing system.

Old and new pipe generally available for service in the larger sizes suitable for the mains for the system are in following classes: old and new black iron standard, new riveted black iron and, recently, new high-pressure concrete pipe. In the intermediate sizes—that is, from 2 to 4 inches O. D., used or reconditioned boiler tubing is obtainable in considerable quantities.

It is the last class of pipe about which the arguments for and against old and new pipe are centered. The bulk of pipe used in most systems is of these sizes, and to date three-fourths of the systems in the southwest have utilized this type of material practically throughout. How well this has been selected, reconditioned, protected and installed, only time will tell, although in some systems rust is already showing through pits, welds and thread connections.

FROM the accompanying remarks the conclusions may be drawn that good system engineering should accompany very careful selection and installation of reconditioned pipe. The engineering of an all new pipe system must be even more carefully performed to maintain proper balance between the economy of smaller sizes and the dangers of its being too small for the purpose and for long continued trouble-free service. The author discusses the first important problem that is encountered in the planning of the installation of an overhead system. Next month he will take up another important question on overhead irrigation in MODERN IRRIGATION.

The real case of the new pipe proponents against the use of boiler tubing does not question so much the heredity of the used tube as it does the careless selecting, reconditioning and protecting of the tubes. New boiler tubes are of high-grade charcoal iron either seamlessly drawn or made with wide lap welds to unquestionably stand high steam pressure and heat with wide margins of safety. For this reason they are usually relieved of further boiler duty long before their race is run. The texture of their metal is such as to be affected only slowly and superficially by oxidization, "ferric oxide" of tubes is in the form of dust rather than in flakes as is the case with lower grade pipe.

However, the action of intense heat and water with its various chemical contents, pits and limes the tubes inside and out. It is in this condition that the various western reconditioning yards receive their stock of tubes and their responsibility begins. It may be said here that not over seventy per cent of the general run of tubes should pass the selection test. The raveled ends resulting from their removal from the boilers are then cut off; the tubes are then placed in a big cylindrical tumbling rattler where water plays on them. The lime and scale is removed more or less depending on length and thoroughness of the treatment. The tubes are then generally tested with water or steam pressure from 100 to 200 lbs. and leaks are either patched by spot welding, or the tube is discarded to the fence post pile.

Protective Treatment

The protective treatment usually consists of submerging a bundle of tubes in a hot dip of asphalt or a petrolastic cement, once or twice and in periods of varying duration to permit the tubes to expand and receive the molten preservative in the pores of the metal.

The reconditioning process of used standard pipe is similar to the foregoing and the dipping of such pipe and new black standard pipe is performed in much the same way, though on special orders the ends of the pipe are sometimes capped, excluding the dipped solution from the inside of the lengths. The application of the preservative should be made within a few days of the pipe's being placed under ground and the pipe should be carefully handled in the meantime to avoid scratching off any of the coating.

Other preservative solutions and coatings are being used to further protect pipe laid in other soils. For instance, red lead has been found superior for pipe to be laid in adobe or clay soil. The tenacious cling of adobe to an asphalt coating, while adobe soil is contracting and cracking through evaporation, is reported to tend to strip a pipe of its protection in a season or two.

OVERHEARD AMONG THE *OVERHEADS*

J. Glover of the Browning Construction company has just returned to Los Angeles from the north where he reports a growing interest in overhead irrigation systems.

The Buckner Sprinkler Golf King No. 3, also their quick coupling, has been specified for the El Sereno Country Club irrigating system on Alhambra Road, Los Angeles, Calif.

Thirty trees, on what is said to be one of the best known overhead irrigated groves, that of F. H. McPherson at San Gabriel, (Calif.) have been equipped with the Brooks spray head, one to each tree. With this system it is said he can get an irrigation very quickly.

Bringing the total of installations to fifty-six, Albert E. Harris has completed systems during the past few weeks for Dr. Gaston of La Verne, 10 acres; L. M. Hill, 7 acres at Glendora; Mrs. F. H. Cannard, 5 acres lemons at Glendora and a small system for J. Shoemaker, Glendora realtor.

The Shoemaker grove at Placentia, (Cal.) and the Visel grove in Santa Ana Canyon southeast of there are said to be pioneer groves equipped with the Vacher Sprinkler head. These systems were both installed by the growers themselves. No expense was said to have been spared to install the work as they desired.

Skeleton pipe line systems to utilize portable sprinkler stands are features of the recent installations of Samuel H. Gerson. The same system was installed recently on eight acres in the San Dimas canyon grove of the Gillete Bros. and a similar installation has just been completed on the Richard's Crown ranch at Corona (Calif.).

A Hadden automatic control system measures the amount of water applied to the grove that is under overhead irrigation on the Citrus Experiment Station of the university near Riverside, Calif. By the control feature the water is turned off and on the various units on a set and predetermined program, permitting penetration into the comparatively heavy soils, between applications of water.

An overhead system on the contour planted hillside grove of limes, lemons and avacados of John Morton, deputy county assessor in North Whittier Heights (Cal.) has just been installed under the engineering plans of Wm. J. B. Stewart. The system operates in three units, and the direct pump equipment, control valves, are all housed in a structure of Spanish design in harmony with the new $40,000 home just completed on the hill-top site.

The largest overhead system in the southwest, that of 63 acres on the foothill lemon property of A. M. Stevens in the North La Verne, (Calif.) district has been enlarged during the past few weeks by the original contractor, Clarence H. Thomas with addition Orr Compound Sprinklers. The 18-acre unit that has been installed is on unplanted land of irregular topography and soil. It was considered waste land, if irrigated by the furrow method, without an excessive expenditure for grading or a concrete pipe system. The area is now being planted with lemon trees with a cover crop.

The irrigator on Mr. Steven's place formerly needed help to get the 63 acres irrigated in 25 to 26 days but he now irrigates the property in 5 or 6 nights' operation.

The Right Pipe for Overhead

(Continued from Page 46)

"White pipe" or galvanized standard is obtainable in 2 inch and smaller sizes and is being increasingly used. Especially is this true above ground for rotary sprinkler risers and straight line nozzle system laterals.

A practical overhead irrigation system should generally avoid the use of much small size pipe; that is, ½ inch, ¾ inch and 1 inch because of the pressure head loss. Liming tendency and structural weakness of such sizes as compared with larger sizes are also a drawback. Where the capacity is small, vibrationless sprinklers or sprays must be used as along the edges of systems, the use of small sizes should be carefully figured.

As 1½ inch I. D. is the smallest reconditioned pipe regularly available, the probabilities of the use of too small pipe in the laterals of overhead systems rather eliminates itself, generally speaking.

WHAT IS *YOUR* PROBLEM

FREQUENT requests for authoritative, unbiased information on overhead irrigation systems, co-ordinating the hydraulic, mechanical and agricultural requirements thereof, has led MODERN IRRIGATION to secure for its readers the services of Lippincott and Stewart, consulting hydraulic and overhead irrigation engineers.

In this department, questions of general interest to overhead irrigators will be answered for our readers.

I have natural gas within a half-mile of my grove. Is it reliable. Would it pay me to bring it to my pump house site rather than use electricity? J. S. T. Foothills, Los Angeles County.

On rates prevailing in your district gas will furnish you satisfactory power with suitable engine equipment for 25 to 35 per cent of the cost of electricity although your power plant investment will be considerably greater, to which should be added the cost of the pipe line necessary. The quantity of power required would determine whether the investment would pay for itself or not.

Do I understand that an overhead system eliminates the necessity of all cultivation? S. T. H., Orange County.

That would be too strong, although there is a great diversity of opinion regarding the cultural care necessary in connection with an overhead system. Where summer and winter cover crops are carried it is practical to get by with discing these two crops under, but one subsoiler run between the rows each way during the early spring dormant period will aeriate and benefit the soil.

Do you think that three quarter inch riser pipes have anything to do with the dry spots between sprinkled areas my system has shown? J. A. R., Butte County.

If the type of sprinkler you mention is used with over thirty pounds pressure the small risers are very largely to account for the dry places. The recoil of the discharging water almost undoubtedly bends back the riser, elevating the angle of trajectory or discharge so high that the water loses distance by rising too high into the air.

Has anything practical been devised to keep overhead water from running down trunks of trees and soaking the root crown? I believe this is a very important matter. G. M. P. Foothill District, Los Angeles Co.

There is a protector, primarily designed to keep ants, spiders and other crawling insects from ascending tree trunks that also performs the above service, very effectively, it is reported.

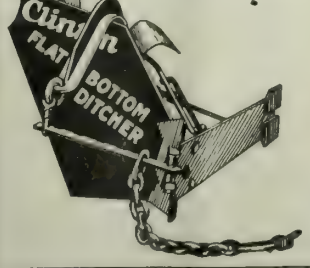
LAYKOLD
EMULSIFIED ASPHALT

ASPHALTIC concrete ditch linings are superior to other types of linings because they are flexible and hence conform at all times to the shape of the bank without opening cracks. If the ditch bank settles, so does the asphalt lining but there is no loss of water. By carefully controlling the weeds with our weed killer, there will be no future trouble from that source, Laykold linings are handled cold, the same as cement concrete, but are flexible.

Crown Bitumens Corporation
315 Montgomery Street,
San Francisco, California

Make Your Ditch a Natural Water Course!



Here are—
5 Advantages:
you'll appreciate in this tool:

1. It builds a ditch which carries more water than a "V" ditch, depth and fall being equal.
2. The "off" horse walks on the flat ditch bottom instead of on the slope.
3. Silt fills this type of ditch more slowly and there is less overflow.
4. Erosion is minimized in the flat bottom ditch.
5. It can be cleaned out with greater ease for it keeps its shape.

SURVEY *of* HYDRAULIC DEVELOPMENT

As Shown by Official Records of the Month -- Local, State, and Governmental

Applications Filed

Among the applications for permits to appropriate water filed with the State Department of Public Works, Division of Water Rights, (California) during the month of July were the following:

Application No. 5128 (Amador & Calaveras Counties)—East Bay Municipal Utility District, 1924 Broadway, Oakland, Calif., for 375 cubic per second and 217,000 acre feet per annum from Mokelumne River tributary to San Joaquin River to be diverted in Sec. 26, T 5 N, R 10 E. M. D. M. for power purposes in NW¼ SW¼ Sec. 26, T 5 N, R 10 E, 13,849 H. P. to be developed. Estimated cost $6,450,000.

Application No. 5129 (Trinity County)—Big Creek Ranch, Inc. care of N. D. Hopkinson, 68 Post St., San Francisco, Calif., for 40,000 acre feet per annum from Big Creek tributary to Hayfork of S. Fork Trinity River to be diverted in Sec. 6, T 32 N, R 11 W, M. D. M. for irrigation purposes on 22,000 acres in T 31 & 32 N, R 10, 11 & 12 W, M. D. M. Estimated cost $200,000.

Application No. 5125 (Placer County)—Victor T. Mathews, Cisco, Calif., for 200,000 acre feet per annum from North Fork American River tributary to American River to be diverted in Sec. 28, T 18 N, R 17 E, M. D. M. for agricultural purposes.

Application No. 5123 (Nevada County)—C. S. Wheeler, Wheelerville via Reno, Nevada, for (1) 500 cubic feet per second and (2) 75,000 acre feet per annum from (1) Truckee River and (2) Little Truckee River tributary to Pyramid Lake to be diverted in (1) Sec. 28, T 18 N, R 17 E, and (2) Sec. 4, T 18 N, R 17 E, M. D. M. for power purposes in NW¼ SE¼ Sec. 34, T 18 N, R 17 E, M. D. M. 11,023 H. P. to be developed. Estimated cost $800,000.

Application No. 5124 (Nevada County)—C. S. Wheeler, Wheelerville via Reno, Nevada, for 75,000 acre feet per annum from Little Truckee River tributary to Truckee River to be diverted in Sec. 4, T 18 N, R 17 E, M. D. M. for irrigation purposes on 20,000 acres. Estimated cost $600,000.

Application No. 5120 (San Joaquin County)—Jack & Sol. D. Klein, care of Ohm & Raab, 517 E. Market St., Stockton, Calif., for 4.19 cubic feet per second from Middle River tributary to San Joaquin River to be diverted in Sec. 1, T 1 S, R 4 E, M. D. M. for irrigation purposes on 335.4 acres in Secs. 6 & 7, T 1 S, R 5 E, Secs. 1 & 12, T 1 S, R 4 E, & Sec. 36, T 1 N, R 4 E, M. D. M. Estimated cost $3,500.

Application No. 5121 (San Joaquin County)—M. G. Oliveira, care of Ohm & Raab, 517 E. Market St., Stockton, Calif., for 4.70 cubic feet per second from Burns Cutoff tributary to San Joaquin River to be diverted in Sec. 12, T 1 N, R 5 E, M. D. M. for irrigation purposes on 377.6 acres in Secs. 13 & 14, T 1 N, R 5 E, M. D. M. Estimated cost $6,000.

Application No. 5109 (Butte County)—James D. and Mary Louise Phelan, Phelan Bldg., San Francisco, Calif., for 3000 acre feet per annum from (1) Philbrook Creek and (2) Butte Creek tributary to Feather and Sacramento Rivers to be diverted in (1) Sec. 16, T 24 N, R 4 E, and (2) Sec. 4, T 21 N, R 2 E, M. D. M. for irrigation purposes on 2080 acres of rice in Secs. 12 & 13, T 21 N, R 2 E, and Secs. 19, 24 & 25, T 21 N, R 1 E, M. D. M.

Application No. 5110 (Butte County)—Parrot Investment Co., 155 Montgomery St., San Francisco, Calif., for 3,000 acre feet per annum from (1) Philbrook Creek (2) Butte Creek tributary to Feather and Sacramento Rivers to be diverted in (1) Sec. 16, T 24 N, R 4 E, and (2) Sec. 4, T 21 N, R 2 E, M. D. M. for irrigation purposes on 16,160 acres in T 21 N, R 1 W, & T 20 N, R 1 W, M. D. M.

Application No. 5091 (Tehama County)—P. B. Cross, Bank of Italy, San Francisco, Calif., for 150 cubic feet per second, and 12,000 acre feet per annum from Deer Creek tributary to Sacramento River, to be diverted in Section 29, T 28 N, R 5 E, M. D. M., Sections 10 or 16, T 27 N, R 4 E, M. D. M., for power purposes in Section 5, T 25 N, R 2 E, M. D. M. or Section 5, T 26 N, R 3 E, M. D. M., 35,795 T. H. P. *or* 18,750 T. H. P. to be developed. Estimated cost $1,800,000.

Application No. 5102 (San Joaquin County)—Henry Peter & Anna Catherine Ponkendref, care of Ohm & Raab, 517 E. Market St., Stockton, Calif., for 3.0 cubic feet per second from San Joaquin River tributary to Suisun Bay to be diverted in Sec. 21, T 1 N, R 6 E, M. D. M. for irrigation purposes on 270 acres in Secs. 16, 17, 20 and 21, T 1 N, R 6 E, M. D. M. Estimated cost $4,000.

Application No. 5103 (Nevada & Placer Counites)—Nevada Irrigation Dist., care of C. F. Meteer, Calif. State Life Bldg., for 125,000 acre feet per annum from Bear River tributary to Sacramento. River to be diverted for purposes in Nevada Irrigation District.

Application No. 5104 (San Diego County)—Ernest W . Cuff, care of Thomas H. King, 920 8th St., San Diego, Calif., for 1.0 cubic feet per second from Cascade Creek tributary to Santa Ysabel Creek to be diverted in Sec. 18, T 12 S, R 4 E, S. B. M., for domestic purposes and irrigation on 100 acres in said Sec. 18. Estimated cost $5,000.

Application No. 5084 (Monterey County)—Geo. C. Humes, M. Simonoff and Wm. C. Lyon, care of Hankins & Hankins, 918 Pacific Bldg., San Francisco, Calif., for 4.22 cubic feet per second and 236 acre feet per annum from Encinal Creek, Milpitas Creek and Arroyo Seco, tributary to Salinas River, to be diverted in Sections 4 and 18, T 21 S, R 5 E, M. D. M., Section 12, T 21 S, R 4 E, M. D. M., for irrigation, domestic, boating, swimming, fishing and fish hatchery purposes in T 21 S, R 5 E, M. D. M. Estimated cost $25,000.

Permits Issued

Among the more important permits to appropriate water issued by the Department of Public Works, Division of Water Rights of California, during the month of July, 1926, were the following:

Permit No. 2580, Application No. 5048 (San Joaquin County) Issued to Helen H. Cleghorn, Stockton, Calif., July 28, 1926 for .22 cubic feet per second from Fourteenmile Slough in Section 16, T 2 N, R 6 E, for irrigation of 18 acres in Sec. 16 and 17. Estimated cost $2,500.

Permit No. 2581, Application No. 4909 (Siskiyou County) Issued to Montague Irrigation Dist., Montague, Calif., July 29, 1926 for 2.3 cubic feet per second from Little Shasta in Section 26, T 45 N, R 5 W, for municipal purposes of Montague, Calif. Estimated cost $8000.

Permit No. 2582, Application No. 4912 (Siskiyou County) Issued to Montague Irrigation Dist., Montague Calif., July 29, 1926 for 50 cubic feet per second from Little Shasta River in Section 26, T 45 N, R 5 W, for irrigation of 17,150 acres within said district. Estimated cost $300.

Permit No. 2566, Application No. 4864 (Yuba County) Issued to Ellen M. H. Lewis, Piedmont, Calif., July 13, 1926 for 3.85 cubic feet per second from Nigger Jack Slough in Section 12, T 15 N, R 3 E, for irrigation of 308.36 acres near point of diversion.

Permit No. 2560, Application No. 4862 (Butte County) Issued to T. L. Quigley, Sutter Club, Sacramento, Calif., July 6, 1926 for 20 cubic feet per second from Lateral "A" Drainage Canal of Reclamation Dist. 833 in Section 4, T 17 N, R 1 E, for irrigation of 892 acres of rice near point of diversion. Estimated cost $5000.

Permit No. 2561, Application No. 4887 (Butte County) Issued to Estate of C. M. Faris, Gridley, Calif., July 6, 1926 for 13.27 cubic feet per second from Lateral "A" Drainage canal of Reclamation Dist. 833 in Section 19, T 18 N, R 2 E, for irrigation of 591.2 acres of rice near point of diversion. Estimated cost $2000.

Permit No. 2575, Application No. 4946 (Tuolumne County) Issued to California Sales Organization, Oakdale, Calif., July 23, 1926 for 0.25 cubic foot per second from Calder Creek in Section 17, T 2 N, R 16 E, for irrigation of 21 acres and domestic and fish culture in Sec. 17. Estimated cost $10,000.

Permit No. 2578, Application No. 3532 (Los Angeles County) Issued to San Dimas Water Company, San Dimas, Calif., July 27, 1926 for 2150 acre feet per annum from Puddingstone or Walnut Creek in Section 10, T 1 S, R 9 W, for domestic and irrigation of 1927.21 acres in the San Dimas and Charter Oak Dists. Estimated cost $160,000.

Power Developments

The Federal Power Commission at its last meeting authorized the issuance of the following licenses:

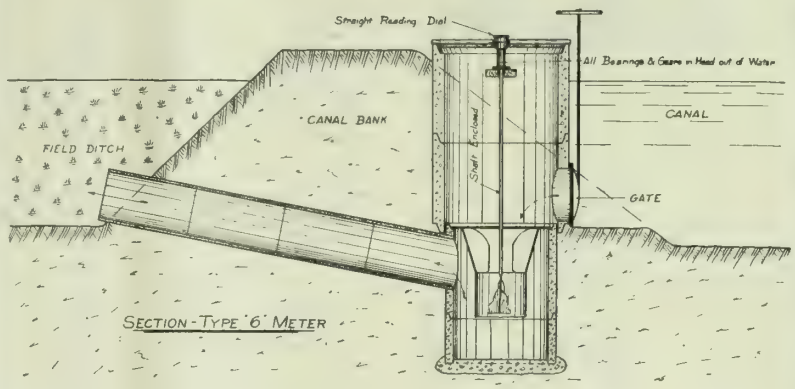
Project No. 95. To Emma Rose, Anna G. Lane, and Hobart Estate Company, of San Francisco, a license for 25 years for a project or Highland Creek in Tuolumne and Alpine Counties, California, partly within the Stanislaus National Forest. A dam about 80 feet in height will be built across Highland Creek, forming a reservoir of about 9,000 ace feet capacity, to be known as the Spicers Meadows Reservoir. This storage of water is necessary to provide for future growth in domestic and irrigation requirements and to augument the water supply to the applicants' existing power plants. The power proposed to be developed will be used in mining and public-utility service.

Propect No. 567. To East Bay Municipal Utility District, of Oakland, a license for 50 years for a proposed power project in Amador, Calaveras, San Joaquin, and Contra Costa Counties, California, to consist of a dam know known as the Lancha Plana Dam, a reservoir, water conduits, a power house equipped with two 5,000 horsepower generating units, and a transmission line about 82 miles in length. The dam will be of the variable radius type approximately 345 feet in height, forming a reservoir with a storage capacity of about 237,000 acre feet. The storage is intended primarily for municipal water supply purposes. The water conduits will consist of three tunnels, each about eight feet in diameter, with a total length of 26,900 feet, and 442,000 feet of 5-foot steel pipes. The transmission line will be of the steel-pole construction type and will operate at 66,000 volts.

Project No. 593. To J. W. Preston, Jr., of San Francisco, a preliminary permit for 18 months for a power project on the Moke-River, the North Fork of Calaveras River, and their tributaries, in Calaveras County, California. The proposed scheme of development will consist of three interconnected power systems. Power system No. 1 will comprise a diversion from the South Fork of Mokelumne River westward into the North Fork of the Calaveras, with a storage below that point in the McCaty Reservoir, from which a conduit will lead to power house No. 1. Power system No. 2, will consist of a diversion from the South Fork of the Mokelumne at a point two miles above its junction with Middle Fork to power house No. 2 on the main stream, located about three miles below the junction of North and Middle Forks. Power system No. 3 will be supplied from a reservoir on the Middle Fork of the Mokelumne 1¼ miles above the mouth of Bear Creek through a conduit leading to a power house on the South Fork of the river, to be situated near the town of Railroad Flat. The power to be developed will be used by the applicant for irrigation or sold to other interests.

Projects Nos. 649 and 651. To George B. McClary, of Chicago, preliminary permits for two years each for power projects in the Rock River, in Ogle and Lee Counties in the vicinity of Grand Detour, and in Winnebago County in the vicinity of Latham Park, Illinois. The proposed development for Project No. 649 will consists of a reinforced concrete dam protected by an earthen dike on the east abutment and a power house integral with the concrete section of the dam. The power capacity of this project is estimated as 2,000 horsepower, and the head at 9 feet. Project No. 651 will include a reinforced concrete dam with

The RELIANCE METER



THE "Type 6" Reliance Irrigation Meter offers you standardized permanent construction at a very low first cost. Their sustained efficiency with a minimum of upkeep has been proven by 12 years usage. Cut shows installation of the 4 sec. ft. size in 24 and 30-inch concrete pipe. This is the standard type of setting adopted by many irrigation districts in Texas and elsewhere who are now equipping all their deliveries with this device. The "Type 6" meter is furnished in sizes ranging from ½ up to 16 sec. ft.

Prices? Most reasonable! A splendid luncheon for 65c or—table d 'hote dinner for $1.00

Entrance also through Hotel Plaza lobby

earthen dikes protecting the east and west abutments with a canal or headrace leading to a power plant a half mile below the dam. The estimated power capacity of this project is 2,160 horsepower and the head 13.4 feet. The developed power is intended for public-utility service.

Project No. 676. To Ray K. Holland, of Ann Arbor, Michigan, a preliminary permit for two years for a power project on the Fox River, in LaSalle County, Illinois. The project provides for the construction of a dam at Wedron creating a head of about 30 feet with a power house having an installed capacity of 2,000 horsepower. The power capacity is estimated to be 860 horsepower. The power, when developed, will be used for public-utility service.

Project No. 681. To the Illinois Northern Utilities Company, of Dixon, a preliminary permit for two years for a proposed power development in Rock River, in the vicinity of Byron, Ogle County, Illinois. The applicant proposes to construct a reinforced concrete dam about 39 feet high and 223 feet long flanked by earthen embankments, making the total length of the dam approximately 11 miles to Rockford, and will have an estimated storage capacity of 1,100 acre feet. The power house will be built integral with the dam and will have an installed capacity of about 1,600 horsepower. The power is intended for public-utility use.

Project No. 621—To the Inland Power & Light Company of Portland, Oregon, a license for 50 years for a power project on the Clearwater River near Lewiston, in Nez Perce County, Idaho. The project includes the construction of a dam and dikes creating a log pond of about 600 acres, a power house, and two transmission lines connecting at the project boundary to a power system supplying public-utility service. The average static head at the power plant is 34 feet, and the estimated power capacity 8,500 horsepower. The proposed ultimate installation will be 10,880 horsepower.

Project No. 588—To the Northwestern Power & Light Company of San Francisco, California, a license for 50 years for a power project on the Elwha River, in Clallam County, Washington, to consist of a reservoir of approximately 20,000 acre feet of usuable storage to be created by a concrete-arch dam 195 feet high, a tunnel 530 feet long, a power house, and a transmission line connecting with the company's existing transmission system. The head on the plant will be 186 feet and the power capacity 8,600 horsepower. The proposed ultimate installation is 16,550

Project No. 608—To Messrs. Giffen, Porter, Pearsall, Freeman, and Knapp, of Los Angeles, a preliminary permit for two years for a proposed power project on the North Fork and the East Fork of the North Fork of Trinity River, in Trinity County, California. The scheme of development provides, first—for the construction of a reservoir on the North Fork of the river which will have a usable storage of approximately 65,000 acre feet, a conduit which will cross the divide between the North Fork and the East Fork of the river near the reservoir into a tunnel and continue down the East Fork to a power house. The total length of the conduit will be eight miles, the proposed installation 20,000 horsepower, and the probable static head on this plant 850 feet. Second—the construction of a reservoir on the East Fork of the North Fork with a usable capacity of approximately 25,000 acre feet, six miles of conduit, and a power house with an installed capacity of 20,000 horsepower located on the same stream, It is proposed to use the power generated for mining and public uses.

OREGON

Among the more important applications for permit to appropriate water filed in the office of Rhea Luper, State Engineer of Oregon, during July, 1926, were the following:

Squaw Creek Irrigation District of Sisters, covering the appropriation of water from Lake Creek & Suttles Lake for irrigation of 16,000 acres. No estimate of cost given.

Also the Squaw Creek Irrigation District applies for the appropriation of 19,000 acre feet from underground waters feeding Blue Lake for storage for irrigation.

Eastern Oregon Light & Power Company, covering the appropriation of water from Grande Ronde River for the development of 1364 theoretical horsepower, at an estimated cost of $810,000.

Hiram Swank of Vancouver, Wash. covering the appropriation of snow water from Blue Bird, Griffin and Washington Gulches, tributary of Powder River for mining in Baker County, at an estimated cost of $2500; also for appropriation of water from Washington Gulch for hydraulic mining at an estimated cost of $1500.

F. B. Ingels of Dufur covering the appropriation of water from Fifteen Mile Creek for irrigation of 24 acres, at an estimated cost of $800.

Roscoe E. Bratton of Grants Pass, covering the appropriation of water from West Fork Jones Creek for irrigation of 15 acres, at an estimated cost of $4500.

J. H. Maxwell of Lewis, Wallowa Co., covering the appropritaion of water from Chesninimus, Gooseberry & Butte Creeks for irrigating of 43 acres.

J. M. Thompson of Camas Valley covering the appropriation of water from a tributary of Mid. Fork of Coquille for irrigation of 25 acres at an estimated cost of $500.

W. G. Wilson of Salem, covering the appropriation of water from three springs for irrigation of 4 acres, at an estimated cost of $200.

P. J. Larson of Portland, covering the appropriation of water from springs and spring creek tributary to Bucannoun River, for irrigation of 4 acres, and supplying water for hydraulic ram and auto camp, in Clatsop County.

E. Beauregard of Hood River, covering the appropriation of water from Spring, tributary to Neal Creek, for irrigation of 35 acres, at an estimated cost of $500.

B. C. Terry of Enterprise, covering the appropriation of water from Silver Creek for irrigation of forty acres.

S. S. Myers of Waurna, covering the appropriation of water from Bee Lake Creek for power plant in Clatsop County, at an estimated cost of $750.

E. L. & C. C. Dickson, covering the appropriation of water from Calapacia River and Ash Slough, for the irrigation of 284 acres in Linn County.

Albert E. Hill of Sutherlin covering the appropriation of water from Calapacia Creek for irrigation of 120 acres.

D. C. Flanagan, E. J. McHugh & William Robitsch covering the appropriation of water from an unnamed tributary of Wilson for mining in Tillamook County, at an estimated cost of $400.

Lydia E. Dean of Grants Pass, covering the appropriation of water from Rock Gulch for mining, for irrigation, at an estimated cost of $200.

Thos. Ogden of Grants Pass, covering the appropriation of water from Shan Creek for irrigation of 10 acres.

valuable information, a revised and up to date membership roster of the Western Irrigation Equipment Association has been authorized.

The membership committee presented five new applications for membership, all of which were favorably received, and the meeting was then turned over to the well drillers, for a discussion of their problems and the formulation of a plan of action designed to be of some practical assistance to this industry.

The next meeting, which will be the regular annual meeting, will be occupied chiefly with the election of officers. The meeting is scheduled for September 8, at the Sacramento Fair Grounds.

Announce A.W.W.A. Program

(*Continued from Page 17*)

M., automobiles will leave for trip to Lower Otay Dam and other points of interest of the San Diego Water System. Lunch will be served as guests of the City of San Diego at the Lower Otay Filter Plant. Return to hotel about 4:00 p. m. Ladies invited.

SPECIAL ENTERTAINMENT FOR LADIES

Thursday, Afternoon: Excursion on San Diego Bay.

Evening: Theatre party.

Friday: Automobile trip through parks and Point Loma.

Editors to Back Boulder Dam

A resolution approving the Boulder Canyon dam project and pledging support for legislation before congress was adopted by the National Editorial Association in their annual convention in Los Angeles the early part of last month. The editors had ample time to see what irrigation has done for parts of the west when they visited a number of the projects and farms. Frank C. Edgecombe, of Geneva, Nebraska, president of the association, suggested to the editors that they voice their approval of the project.

Correction in Table

MODERN IRRIGATION announces that an error was made on page 32, table one, fourth column, in the July issue. The fourth column and an additional column of this table should have read as follows:

AMONG OUR CONTRIBUTORS

Editorial Jottings About Current and Forthcoming Feature Articles, Dealing With Practical Problems of Hydraulics, and the Men Who Have Written Them

CHARLES A. JENSEN attended college at the universities of Utah and Nebraska. He has spent some 15 years in the U. S. Department of Agriculture in the bureau of soils and bureau of plant industry. In this line he specialized in alkali and plant nutrition, spending some five years in citrus investigations in and about Riverside, California. In Colorado he studied sugar beet problems when he was with the American Beet Sugar Company. About three years ago he left his position as field superintendent of the National Orange Company, Riverside, California, where he served for four and a half years, and went to the Limoneira of which he writes in this issue.

DR. ELWOOD MEAD needs no introduction to the irrigation fraternity. His position as Commissioner of Reclamation assures any utterances of his careful reading. Born in 1858, he received his C. E. degree from Iowa State College in 1883. From 1883-84 he was a professor in Colorado Agricultural College, and again from 1886-88. He was territorial and state engineer of Wyoming from 1888 to 1899. Later he was chief of irrigation and drainage investigations of the federal government; professor of institutions and practices of irrigation, University of California; chairman of state rivers and water supply commission, Victoria, Australia. For a number of years after 1915 he served as professor of rural institutions, University of California. He has been chairman of the land settlement board, till today he is Commissioner of Reclamation. He is a member of the A. S. C. E. and British Inst. C. E. Among the works that he has written on irrigation is "Irrigation Institutions."

DOUGLAS G. MCPHEE has been executive editor of Modern Irrigation since its inception over a year ago. He "covered" his article while on his new mission with the editorial staff of "Western Advertising."

WILLIAM J. B. STEWART is a consulting hydraulic and overhead engineer who conducts the monthly department of Overhead Irrigation. He also conducts the inquries department of overhead. This department has been opened for the convenience of the profession.

DON J. KINSEY has for some time been connected with the Los Angeles Bureau of Water and Power. He writes the current article after he has "gone through the battle" with the Owens project. His chief work consists of gathering data and material for the profession on the Los Angeles Water and Power bureaus.

PHILIP J. HASBROUCK, who writes about Fontana, was graduated from Cornell University in 1896 with a degree in Mechanical Engineering. From college he went to the Pittsburgh district to spend some ten years in the steel industry as engineer, constructionist, and operator. In 1908 he came to California and has since been connected with engineering work related to water supply and irrigated lands.

Wartimes found him a captain of field artillery in France, while he is now a major of field artillery in the organized reserves.

Since 1925 he has been in Fontana in charge of water development and operation of irrigating and domestic water systems. He is a member of the San Bernardino chapter of A. A. E., having at one time been president of that chapter.

MILO B. WILLIAMS, who writes about concrete pipe in the hydraulic engineering department of this issue, is retained as consulting engineer by the California Associated Concrete Pipe Manufacturers. In 1917, when the value of concrete pipe for irrigation development attracted the attention of the United States Department of Agriculture, Mr. Williams was placed in charge of a study of the manufacture and uses of concrete pipe under the direction of Dr. Samuel Fortier, chief of irrigation investigation at Washington, D. C. The work met with the hearty co-operation of the pipe manufacturers who came to place great confidence in the work that Mr. Williams accomplished. He continued his studies in the years to come and the success that he attained has been such that today he finds himself even more closely allied with some of his former collaborators in government work by his association with the California manufacturers' group as consulting engineer. Mr. Williams had charge of the concrete pipe tests by the California Associated Concrete Pipe Manufacturers conducted at San Jose, California, a few weeks ago and his report of these tests will be published in a forthcoming issue of MODERN IRRIGATION.

THIS month's cover is a reproduction of the architect's vision of the Coolidge Multiple Dome Dam to be constructed shortly in Arizona. MODERN IRRIGATION is indebted to the architects, Wright and Gentry, Long Beach, Calif., for the photograph.

IT IS DIFFICULT to refrain from commenting briefly on a few of the unusual and highly practical articles scheduled by the editor for forthcoming issues of MODERN IRRIGATION. There is in prospect another article of the "What Irrigation Has Done for My State" series, this one having been written by James Graves Scrugham, governor of Nevada, who will tell of the reclamation and irrigation accomplishments in his state, the irrigated area of which, at present, comprises 560,000 acres.

"Irrigation in Mexico" is the title of a broad survey of the Mexican situation that has been prepared for this journal by R. A. Hill, of Quinton, Code and Hill, Los Angeles. Mr. Hill's knowledge of his subject comes from first hand contact with Mexican projects and people, the material for his article having come from personal interviews with President Calles, ex-President Obregon and members of the Mexican reclamation and irrigation committee. Many of the intensely interesting facts brought out by Mr. Hill in this paper have never before appeared in print.

OTHER EQUALLY vital subjects are to be covered by competent irrigation authorities in coming issues, but rather than devote more space to announce the nature of these articles, it might perhaps be best to adopt the method of the drama reviewers and not tell too much.

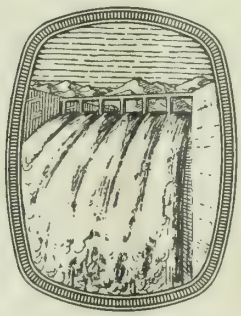
HERBERT HOOVER

Who came out of the east last month to view the developments in reclamation and irrigation that have transpired since his last western tour; and who came, too, to re-affirm more strongly than ever his creed of water development in the United States. Mr. Hoover urges that we consider all water projects as one comprehensive national undertaking, basing his plea on the fact that every major water development must benefit *all the people* and should therefore receive universal support. Politics and litigation, he explains, "create much feeling over water development, but not much development."

MODERN Irrigation
The Magazine of Applied Hydraulics



Volume II SEPTEMBER, 1926 Number 9

The Progress *of* Irrigation

TWO men from Washington have recently given to the west their views on reclamation and irrigation, one speaking from the standpoint of the engineer and the other taking the view of the economist. The men are Herbert Hoover and Dr. Elwood Mead, both of whom have been on the Pacific Coast during the summer.

Hoover, an eminent engineer, has said after a tour of inspection of the western projects, that the time has come when we must take an enlarged vision of the future development of the water resources of the country. His view of the future is almost staggering to the irrigator who sees only his own problems and his own needs in enlarged perspective and fails to grasp bigger needs and problems that affect the whole country's water development. As Hoover himself puts it, "We must no longer think in terms of single power sites or single storage dams or single land projects, or single irrigation improvements; we must think (and thanks to science and engineering we can think) in terms of the co-ordinated, long-view development of the national water resources."

He touches, too, on the regrettable fact that the possibilities of such development are "fast drifting into the muck of litigation, political opposition, and interstate quarrels which could be solved by the determination of broad national programs." He has told his audiences in the west that sectional controversies settle nothing, and engineer-like has added, "Water development can be settled only by steam shovels and the pouring of concrete."

It is important to remember one thing that Hoover himself points out in reference to any broad national program of water development; namely, that such development could it be completed tomorrow, would put under cultivation large areas of land that would bring about overproduction; but he asks us not to overlook that such development will take many years, that the population of the United States will be increased by 40,000,000 people in the next quarter of a century, and that before the big projects now under discussion can be completed efforts will have to be made to provide food for that increase. The program that Hoover outlines, if started at once, could not affect agriculture for fifteen years, he says.

Dr. Elwood Mead, Commissioner of Reclamation, has also given an interest-

ing viewpoint on federal reclamation. Dr. Mead has called attention to the fact that while the engineering achievements of the bureau of reclamation demonstrate that it has both the integrity and the ability to carry out its complex and difficult task, many of us are still holding to what he calls the "erroneous and dangerous idea" that reclamation can be made a success if we leave settlement and farm development to take care of themselves.

In respect to farm development, he asserts, our reclamation policy is a quarter of a century behind that of other countries. It is true, as he says, that the engineering side of federal reclamation has had all the attention and has therefore attained some considerable measure of success, whereas the economics of farming have been overlooked. Both are fundamental and should, and no doubt will, have equal attention.

Dr. Mead makes the interesting contention that the economic factor of preparing land for irrigation is not so much a farming operation as an engineering operation. There is logic to his assertion that preparing land for irrigation is a part of construction and ought to be so regarded, for the settler is as a rule used to methods of farming employed in a humid section, and is not equipped physically or financially to do the preparatory work on the irrigated farm. A carefully thought-out program for making farms ready for cultivation will attract more and better farmers to new projects.

Here then is the pressing problem of federal reclamation; but with the problem recognized and with the better forces for agriculture interested in it there is every reason for an optimistic viewpoint. The solution may not be just around the corner, but it surely is in sight.

As progress accounts and accounts of new projects are chronicled from day to day, one is impressed with the thought that the Pacific Southwest is barely on the threshold of achievement, despite its miraculous growth. It must be judged, not by what it is, but by what it is destined to be. Population is growing faster than the average—greater and greater demands are made upon the productiveness of the cultivated areas—and it has become a matter of immediate importance to lay constructive plans for the future development of California's greatest resource—water.

Irrigation means new wealth, new resources, new land for settlement, new opportunities for the farmer. By means of irrigation the Pacific Southwest will be able to meet the constantly increasing demands of this country's fast growing population.

In California alone, so successful has been development of irrigation, that in the past 35 years, the agricultural production has jumped from $90,000,000.00 to more than $600,000,000.00 with a consequent tremendous increase in the value of the farm land. And so successful has been its development, that the annual value of the crops raised through irrigation now exceeds the total investment in irrigation projects.

In California alone, there are 96 active irrigation districts comprising an area of some 4,000,000 acres. In addition, the United States Reclamation Service operating on a huge scale has added to the productiveness of the West through 28 separate enterprises that have been successfully negotiated. More than 480,000 people now live on some 37,000 farms created and irrigated by government enterprise, according to an estimate made by Commissioner Elwood Mead in his Lake Tahoe address in June of this year.

A total of 1,692,700 acres of land have thus been added to the solid foundation upon which Western business can be profitably built.

On to San Diego!

OCTOBER 28, 29, 30, are the dates for the seventh annual convention of the California section of the American Water Works Association. The convention will be held in the San Diego Hotel at San Diego, California. Waterworks authorities and others well known to the profession are on the program, the details of which are already well known to waterworks engineers through their publication in the August issue of Modern Irrigation.

Those who attended last year's convention have happy memories of that occasion, both from the standpoint of the practical benefits derived from the program and the recreation from daily cares made possible through the thoughtfulness of the entertainment committee. This year's meeting, in the words of Sinclair Lewis' Babbitt, has all the earmarks of being "a bigger and better" convention.

Final arrangements for the three-day session will be published in the October issue—or first annual Water Works issue—of Modern Irrigation. Both the October and the November issues will be big waterworks numbers, however, as a complete account of the convention will be carried in the latter number.

DR. W. L. POWERS

Feasible or Not?—What are the Factors that Decide?

Political, Physical, Social and Economic Considerations Must be Properly Weighed in a Survey of Any Irrigation Enterprise

By DR. W. L. POWERS*

IN THE EARLY development of irrigation, engineering problems were given major attention. A more or less new concept was accepted, when, ten or twelve years ago, public opinion was thoroughly aroused to the necessity of giving careful attention to soil and agricultural conditions; as a result of which soil and agricultural feasibility surveys came into demand. Recent conditions have re-emphasized this newer idea. The unprecedented agricultural depression of the past few years, with low crop values on the one hand and increased cost of fitting and equipping irrigation farm units on the other, has increased the relative importance of economic surveys on proposed projects, and of readjustments in an economic way on existing reclamation enterprises.

The need and use of such surveys is well illustrated in Oregon. There has been a heavy demand for assistance from the Oregon Experiment Station in making soil and economic feasibility surveys and more than 3,000,000 acres of land in proposed reclamation enterprises, including irrigation and drainage propositions, have been examined. Unfortunately, the time and means available for these surveys for the most part have been only sufficient to permit general surveys to be made.

These surveys have included a general soil survey with the aid of the topographic base map furnished by project engineers to determine the extent and characteristics of the different types of soil on the project, their usable water capacity, general fertility, reaction and net water requirements. Attention has been given to climatic conditions, crops suitable, and average probable yields, and to the size of farm unit, type of agriculture, and probable productive value of the land under irrigation.

Survey a Pre-Requisite

In the open country in eastern Oregon, a reasonable productive land value per acre is $25 to $33 per acre for each ton of alfalfa raised on an acre in a year; i. e., 3-ton land may be worth $75 to $100 per acre. Preliminary engineering and soil surveys as well as detailed studies should go hand in hand. Often it has been possible to modify the outlines of the project substantially in order to include the most irrigable land and eliminate the land that is rugged, stony, shallow, and more alkaline.

From the experience gained through these surveys, it is felt that future surveys should be detailed farm unit surveys that will show the number of acres of different classes of irrigable land on each farm. The methods to be employed by state, federal, or professional persons undertaking such work may perhaps be more clearly defined at this time and the factors affecting the feasibility and success of a reclamation project will be briefly described here in the hope of giving a clear concept of this work.

The factors affecting feasibility of reclamation projects may be grouped under four headings; namely, physical, economic, social, and political.

Political Factors Important

Political factors and policies may affect the value of land and water. A united community that is permeated with a spirit of pluck, determination, and enterprise is a great psychological asset to any project.

Social factors affecting the value of land and water include racial types, religious creeds, and social, class and recreational facilities.

The physical factors affecting the value of land and water will include, besides the engineering features, the soil, topography and drainage, as well as climatic and health conditions.

The most important property of the soil, from the irrigation standpoint, is its usable water capacity. Good depth, smooth topography, and good natural drainage, as well as loamy texture are important. A neutral reaction, or freedom from alkali, and freedom from killing frosts, as related to the drainage conditions, are important, as is also the healthfulness of the project. A large supply of organic matter and plant foods is desirable, but these can be supplemented, if deficient.

A soil, however good, may be inactive unless man uses it. The American Indians had access to the same soils as are available to the use of the present generation. It required Yankee enterprise to develop and utilize the soil and water resources of the nation. The west's main opportunity for development is through the irrigation and peopling of its arid lands.

Anatomy of Soils

Soils may be compared to folks. The mineral fraction of the soil constitutes its skeleton, the clay material its fleshy coating or lining, and the soil solution its circulatory system. Soils must have aeration, they digest organic matter, and, finally, there must be elimination to avoid the accumulation of alkali or toxins.

Most soil treatments are aimed at regulating circulation, respiration, or nutritional conditions in the soil. Irrigation and drainage regulate the circulatory system of the soil. Soils have youth, maturity and age. The maturing and aging of soil under arid and semi-arid conditions gives rise to different layers, or horizons, which may be compact, fine textured, or tight in nature.

The high lime contents of these arid and semi-arid soils are favorable to continued production. The readiness with which soil-building legumes are grown under irrigation affords ready means of keeping up the productiveness or of extending the age or life of a soil. Proper

*Dr. Powers is in daily contact with the problems of agricultural feasibility surveys by virtue of his position with the Agricultural Experiment Station of the Oregon Agricultural College.

Navajoa, Sonora—a representative Mexican community. The plaza, hub of social and business life, may be discerned at the left center. The offices of ex-president Obregon (1) and his private home (2) have been marked for identification. In the background, the Mayo river, now the subject of active irrigation development.

R. A. Hill Discusses the Yesterday, Today and Tomorrow of Irrigation

IN MANY of its irrigation practices, developed through centuries of dependence upon artificial regulation of water supply, Mexico is able to teach its northern neighbors valuable lessons.

How far irrigation had been developed, or whether it had been practiced to any considerable extent, when the conquering Spaniard came to Mexico and took the country from its aboriginal inhabitants, it is hard to say. It has now been practiced for so many hundreds of years that it is impossible to determine, and not particularly vital, whether its principles were imported from semi-arid Spain, or whether some rudimentary application of irrigation was known before the advent of the conquistadores.

The physical division of Mexico is largely one of altitude. It is possible to start at Vera Cruz, on the east coast within the true tropics, and to pass through a country of temperate clime, while snow-capped mountains are visible from the windows of the train.

Aside from the influence of elevation, there is a wide diversity in the amount of rainfall. Practically all of Mexico receives most of its rainfall during the summer season, as is typical of countries within the tropics. Consequently, although there is a comparatively large annual rainfall throughout much of Mexico, excepting the northwest and the *Mesa Central,* the rainy season is so short that some artificial means is essential for the furtherance of agriculture.

Important to the United States

Along the west coast, and particularly between Guaymas and Tepic, there is an immensely productive region whose future development depends largely upon the construction of storage works. This portion of Mexico is closest to our own Pacific Coast, and its development is of the greatest importance not only to Mexico but to the United States as well. Along the east coast the distribution of rainfall is somewhat more uniform, so that irrigation from unregulated streams has been practicable.

Laws and customs have naturally grown up regarding the use of waters from the rivers which even today are as advanced and in many instances more practicable than the laws in force in many of our states.

The Mexican law of appropriation of the waters of any stream may be considered the foundation of the law of appropriation which holds in Arizona and to some degree in California and other States. The riparian law, which was developed in countries where no lack of water existed, was passed down to us from the English settlers of the United States and is far less applicable to the semi-arid regions than is the Mexican law of appropriation.

Under Federal Control

In Mexico the control of the waters is very largely in the hands of the federal government, rather than under the direction of the individual States. This is a natural outgrowth of the political history of the country which until a few years ago was known as the Republic of Mexico, and only recently became the United States of Mexico.

A law has recently been passed which provides for the irrigation of lands by the federal government. The *Comision Nacional de Irrigacion,* created by this act, resembles in many respects the Bureau of Reclamation of the United States.

The Yaqui River winds through treeless banks, typical of Mexican streams.

Typical Mexican scenes, reflecting the primitive conditions. ABOVE: An adobe casita, where the Mexican peon lives, with family, dog, pig, rooster and hens. BELOW: Peon laborers working on the construction trestle for a diversion dam on the Yaqui River, state of Sonora.

Mexico

Has practiced irrigation for centuries, yet is far behind the United States in the development of irrigation enterprises on a co-operative basis.

Has laws affecting irrigation which are more practicable and successful than the confused water laws in the United States.

Has patterned her recently created Comision Nacional de Irrigacion after the United States Bureau of Reclamation.

Is attempting a new policy of governmental development based on a pay-as-you-go principle, calculated to make irrigation projects financially solvent and increase government land holdings.

Must depend largely upon colonization for future success, for the native is not usually a good farmer.

in the Land of *Mañana*

The Federal Government of Mexico had for an example the situation in the United States, wherein the settlers have not and in many cases probably will not reimburse the government for expenditures entailed in the construction of irrigation projects. The new irrigation law of Mexico, therefore, provides for the payment to the government of the cost of construction at the time that the construction is executed.

It is provided that repayment will be effected by the landowners turning over to the government enough of their land to meet the cost of development. According to the terms of the act, the capital of no individual will be reduced. For example, if a landowner has a thousand acres the potential value of which is $50,000, he will be allowed to retain that amount of land which, at its face value after irrigation is developed, will aggregate the same amount. That is, if the land is worth $100 per acre after development, he would turn over to the government five hundred acres and would retain five hundred.

The result of the operation of this law will be to place in the hands of the government a large amount of land within each of the irrigation projects which it undertakes.

Within Mexico there is no public land, as we in the United States consider public land. There has been, therefore, no opportunity for the people of Mexico to acquire land except by purchase from private owners. These private holdings date back to the original Spanish grants, and in many cases are of tremendous extent. This control of the land of Mexico was one of the fundamental causes of the revolution, and it has been the aim of the government to make possible the division of land among its people.

Devise Credit System

The lands which the Government takes over within the irrigation projects, in reimbursement for money expended on construction of irrigation works, will be sold to citizens of Mexico, or to those who declare their intention to become citizens. It is generally recognized that only a very limited number will be able to purchase this land outright. There has been established in Mexico, however, the *Banco de Credito Agricola,* (Agricultural Credit Bank) which in many respects is similar to our Federal Farm Loan Bank. Through the agency of this bank selected individuals with little or no capital will be able to purchase and develop these government lands.

The primitive is always picturesque. This Mexican maiden is doing her matutinal duties in an age-old way.

Although the federal government of Mexico is now investigating various projects under the terms of the irrigation law, construction has not yet started on any project, so that it is impossible to express any opinion as to the operation of the law. The operation of the new law does not preclude private development. In fact, it provides that the government will take over private projects only upon failure of the private interests to effect the development.

The methods employed in the irrigation of lands in

(*Continued on Page 22*)

A busy scene at harvest time on a California ranch. The tenant farmer in the West represents a large proportion of the agricultural population, but in many cases the tenant is among the most progressive and successful ranchers of the community

Farm Tenancy in the Irrigated West

Ever an Important Economic and Social Problem in an Agricultural Community, Tenancy Has a Special Relation to the Great Sections Dependent on Irrigation

By H. E. ERDMAN*

TENANCY is often spoken of as one of the outstanding evils of agriculture. There is a lot of discussion of methods of correcting the evil—whether it be real or imagined. We find that in the United States tenancy has been increasing with every census. The figures for five census enumerations for the whole United States and for several individual states are shown in Table I.

TABLE I—*Per Cent of Farms Operated by Tenants in the United States and in Selected States. Census Years 1880-1920*

Census Year	United States	Illinois	Mass.	S. Dak.	Oregon	Calif.
	%	%	%	%	%	%
1880	25.6	31.4	8.2	4.4	14.1	19.8
1890	28.4	34.0	9.3	13.2	12.6	17.8
1900	35.3	39.3	9.6	21.8	17.8	23.1
1910	37.0	41.4	8.1	24.8	15.1	20.6
1920	38.1	42.7	7.1	34.9	18.8	21.4

Preliminary figures issued by the Bureau of the Census show California with a decline from 21.4 per cent in 1920 to 14.7 per cent in 1925, although there was an increase in the number of farms from 117,670 to 136,409. In other words, there was actually a decrease in tenancy in the face of an increase in the number of farms. I do not have a satisfactory explanation of this phenomenon. Perhaps the Alien Land Law had much to do with it. Perhaps, also, many tenants became owners of farms between 1920 and 1925. It may be that a few formerly tenanted farms are now operated by hired managers. Probably all three reasons are important.

Tenancy is by no means confined to the United States. It is of interest to note the relative proportion of tenancy in various important nations as set forth in Table II.

TABLE II—*Farm Tenancy in Selected Countries*†

Country	Year	Per cent of all farms operated by tenants
United States	1920	38.1
England	1914	88.9
Argentina	1914	38.5
Ireland	1916	36.0
China	1920	28.1
Germany	1907	25.4
Canada	1921	7.9
Japan	1921	28.5
Denmark	1918	8.0

†See article in Yearbook, U. S. Dept. Agr., 1923, pp. 507-600.

In many of these countries there has been more or less discussion of the evils of tenancy, yet no country has as yet succeeded directly in eliminating it.

Why, we may ask, do we have tenancy? Two fundamental facts underlie tenancy as an institution. They are: (1) there must be a change in farm operators on any given piece of land about three times in a century because farmers naturally grow old and drop out as active farmers, and (2) young farmers, except where they inherit wealth at an early age, have no money with which to buy farms.

If our credit machinery were sufficiently flexible we might arrange for every young man to buy who so desired. But that would hardly be wise. Too much inexperience would make for inefficiency. Moreover, there are other reasons why we have tenancy. Let us note some of the more important ones. In the first plae, how and why do persons who cannot or do not want to farm come into possession of farm land? Here are some of the most common reasons:

1. Many persons inherit land.
2. Lenders find that they have to foreclose mortgages.

*Professor Erdman is Professor of Agricultural Economics, Division of Agricultural Economics, College of Agriculture, University of California.

3. Investors buy because they consider land a good and, above all, a safe investment.

4. Speculators buy land because they expect prices to go up.

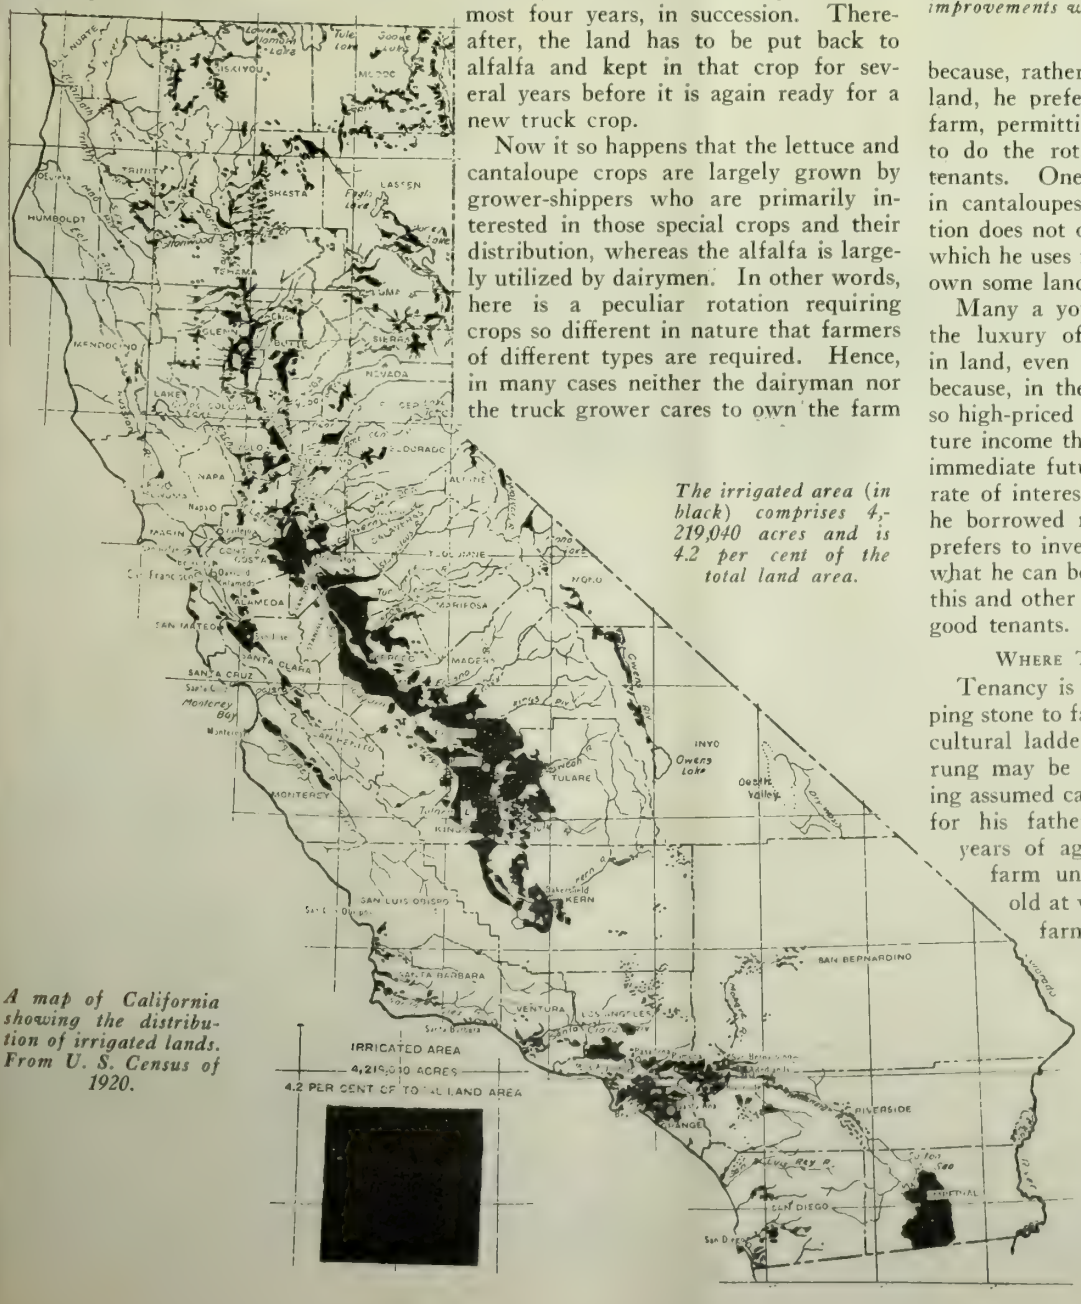
5. Promoters buy because they expect to profit by resale.

Now, all these classes may find that tenancy is the best way for them to handle the land. Operating by hired managers has not, in general, proved successful. The first two classes might sell, but that is not always feasible as it may take time before an estate can be settled. Administrators may not want to take the responsibility of reinvesting funds, and the market for land may be dull. On the other hand the land may be considered a good investment.

So far, we have not mentioned the most important reason. Retired farmers find that tenancy is an excellent way to transfer property to children. A Wisconsin study a few years ago showed that in a community which was probably typical of many in the middle west and elsewhere, nearly half of the rented farms were rented to relatives of the landlord—mostly to sons or sons-in-law.

In addition to the above, there are many peculiar or special reasons for the existence of tenancy. For example, in Imperial County, California, in 1925, 46.7 per cent of all farms were operated by tenants. This is by far the highest figure in any California county and is caused by a peculiar situation in the Imperial Valley. Much of the land there is being used for two main purposes. One is the growing of truck crops, such as lettuce and cantaloupes, which can be grown on the same land for only about two or three years, or at most four years, in succession. Thereafter, the land has to be put back to alfalfa and kept in that crop for several years before it is again ready for a new truck crop.

Now it so happens that the lettuce and cantaloupe crops are largely grown by grower-shippers who are primarily interested in those special crops and their distribution, whereas the alfalfa is largely utilized by dairymen. In other words, here is a peculiar rotation requiring crops so different in nature that farmers of different types are required. Hence, in many cases neither the dairyman nor the truck grower cares to own the farm



The irrigated area (in black) comprises 4,219,040 acres and is 4.2 per cent of the total land area.

A map of California showing the distribution of irrigated lands. From U. S. Census of 1920.

Seven-months-old peach trees on a Delhi (California) ranch, receiving the irrigation so vital to their profitable production. Such improvements will not be undertaken by tenant farmers.

because, rather than to rotate on his own land, he prefers to move from farm to farm, permitting the owner of the land to do the rotating through changes in tenants. One of the largest operators in cantaloupes and lettuce in that section does not own a square foot of land, which he uses for that purpose. He does own some land, but he has that in fruit.

Many a young farmer cannot afford the luxury of investing or speculating in land, even though credit is available, because, in the first place, much land is so high-priced on account of expected future income that he cannot realize in the immediate future anything like the same rate of interest he would have to pay if he borrowed money. Consequently, he prefers to invest all his own capital, and what he can borrow, in equipment. For this and other reasons we have some very good tenants.

Where Tenancy Is Desirable

Tenancy is often spoken of as a stepping stone to farm ownership. The agricultural ladder in which tenancy is one rung may be illustrated by the following assumed case! Suppose a man works for his father until he is twenty-two years of age, then rents his father's farm until he is thirty-two years old at which time he inherits the farm. Suppose that he farms on his own account until he is sixty-two, when he in turn leases to his son. Upon his death, at the age of seventy-two, the farm passes by inheritance to the son. If this were the universal procedure, 25 per cent of our

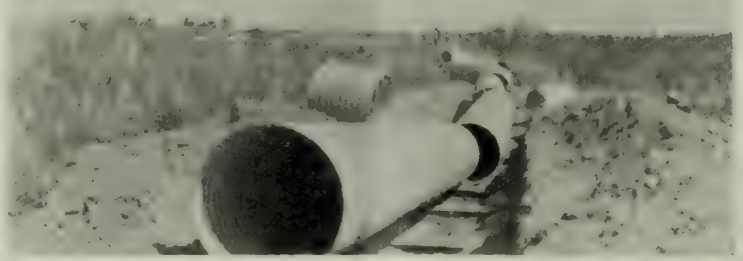
The Imperial District Meets Unusual Drainage Problems

Unique Situation of the Lower-than-Sea-Level District Calls for Ingenious Systems of Drainage of Valley Lands.

ABOVE: The district uses a clam-shell bucket in canal maintenance. It digs a deep, narrow channel, and permits the tules to grow up on each side, shading the ditch and preventing growth in the ditch proper.



LEFT: Drainage activity near the Salton Sea—a line of 18-inch, 14-gauge, close riveted and soldered Armco pipe, ready for installation. BELOW: Lennon type galvanized flumes are used extensively in this work. Interiors of flumes, and exteriors at the joints, are painted for additional durability.

IMPERIAL VALLEY presents to irrigators a problem not encountered on most irrigated projects. As the climate of the valley is one in which crops can be produced during the entire year, the drains are never given an opportunity to develop any appreciable underground storage reservoir, or a chance to get ahead during a season of non-irrigation, but are kept constantly supplied with the excess water from irrigation which is not taken up by plant roots. This, no doubt, has the effect of leaching, except in the districts where the water table is held so close to the surface that capillary action can continue to take place.

The unique situation of the valley, indeed, makes all of its irrigation problems somewhat unusual. That portion which lies within the United States is situated at the extreme southeastern portion of California, and lies some 40 miles west of the Colorado River; also west of a very long range of now quite famous sandhills. The elevation of the valley ranges from about 30 feet above sea level at the international boundary line near the East Mesa to 250 feet below sea level at the edge of the Salton Sea, which marks the northwestern extremity of the valley.

The valley has been built up by periodic overflowing of the Colorado River from its delta to the south into the lower area of the Salton sink. This overflowing has brought in a variety of soils with the very fine silts predominating. The exception is to be found around the rim of the valley where evidences exist of an ancient beach line. In these districts the soil is very sandy and ground water movement is very free. While the floor of the valley is largely composed of the finer, tighter soils, it has been so built up that the strata of nearly impervious materials are invariably broken by strata of sand; it is through these sand strata that the principal ground water relief is obtained.

Portions of the Valley have for several years been provided with quite an elaborate system of wasteways intended to carry off excess surface water. It is in these districts that the largest areas of seeped land were first found. It seems that the fact that means were at hand to care for any extra water caused the irrigators in these districts to be negligent and to let more water pass over and into the soils than was actually required by the crops. The excess water, passing into the soil, quickly built up the water table.

The open type of drain has been used almost exclusively thus far, the reason being that practically all of the first construction was primarily to provide main outlets. The ultimate capacities of the majority of the drains thus far constructed could not be determined due to continually developing seeped areas.

About two miles of tile drains have been built and an additional 4,000 lineal

What the Colleges Are Doing for Irrigation in—

Anticipating the Problems of Tomorrow's Irrigators

By S. H. BECKETT

Associate Professor of Irrigation Investigations and Practice, College of Agriculture, University of California

CHEAP WATER development is practically a thing of the past in the West. New irrigation enterprises, developed at large cost, are placed in direct competition with older districts, many of which have been developed at low cost, and with comparatively low maintenance and operation charges. To facilitate meeting this competition, there will be created in the future a much more insistent demand for additional information concerning increased production and decreased production costs.

There are many questions which the irrigator of the future will ask—and will expect to have answered—but in the phase of the problem directly concerning the application of the water to the land, there are four principal queries, generally important to the present-day irrigation, but to be of increasing importance to the irrigator of tomorrow. They are:

1—What quantity of water per acre is required for economic irrigation of the particular crop in question, both at the margin of the farm, and in the soil, as moisture available for plant use?

2—What is the proper frequency of irrigation, and what depth of water should be applied per irrigation, for various crops and various soil types?

3—How can this water be most economically applied, considering the topography of the land, soil type, size of available irrigation head and character of crop grown?

4—How can waste in transportation, delivery and application be reduced, and what conditions govern the practicability of installation of such improvements as ditch-lining, underground or surface pipe delivery systems, modern gates, valves, etc.?

In order to be of greatest service to the irrigator of tomorrow, it is essential that those directing teaching and research in irrigation in the various colleges should anticipate these and similar questions, which represent the most imperative irrigation problems of the future.

Such problems are legion—mainly concerned with economics, but involving a host of questions directly relating not only to the delivery and application of water, but touching also the matter of justifiable expense in land and improvements, marketing facilities, production costs, and so forth.

And what are the colleges doing to answer these questions?

Early Study Inadequate

During the past twenty years, different state and Federal agencies—including western colleges—have had under investigation various phases of these problems. Early investigations, dealing with the economic quantities of water to be applied in irrigation, consisted almost wholly in the measurement of water applied to the project as a whole or to the individual farm, the economic use being obtained by comparing yields to corresponding quantities of water.

These investigations covered a wide range of soil, climatic and crop conditions, each institution interesting itself in the particular phase of the problem which was of the most immediate importance to the agriculture of its own community. These observations naturally showed a wide variation in methods of procedure and the results obtained, although much valuable information resulted in determining reasonable water requirements for various crops. These investigations, however, did not

(*Continued on Page 27*)

The Colleges

PROBABLY no single force in irrigation wields so mighty an influence in its advancement as the colleges and universities of the West. These institutions, by maintaining special divisions for the study of the subject, and encouraging research by both students and professoriat, have written a brilliant record of achievement. Irrigation as an industry has been singularly fortunate in the type of interest which it has stimulated from the colleges. In most cases this has been the direct antithesis of pedantic, academic curiosity. It has been, rather, the intelligent, far-visioned and practical efforts of men familiar with the irrigator and his problems to meet his needs in the most direct and unselfish way.

The work which the western schools are doing for the industry is many-sided. While it touches many abstruse and complex phases of the technology of irrigation, at the same time it is performing services easily understood and evaluated by the non-technical man. In a series of articles prepared by leading educators of institutions of higher education in Arizona, California, Oregon, Washington, Idaho, and probably other western states, MODERN IRRIGATION is presenting to its readers a series of sketches, of which the accompanying article is the first, giving an outline of what these services actually involve. Each of these articles, in addition to being an illuminating description of the work of the colleges for the industry, will contain information of direct practical interest to the reader.

Vol. II SEPTEMBER, 1926 No. 9

Dedicated to Waterworks

FORTY-FIVE years ago at St. Louis, Missouri, the American Water Works Association was born. The engineers of that day who constituted the last authority on waterworks matters were some of the first of the professional men in this country to discover that the association idea is not only desirable, but quite essential, from an industrial standpoint. Cemented by a community of interests the organization flourished, the membership growing from a handful in 1881 to over 2500 in 1926.

The California section of the association has come as a natural outgrowth of the big development that the west has seen in the last quarter of a century. The California section's growth has paralleled that development. Since 1920 the association's year of activity has, each season, been brought to a climax by the annual convention, this year's meeting being scheduled for October 28, 29 and 30 at San Diego. The 1926 convention, by all signs, is to be the greatest, in point of attendance and the general excellence of the program, of all those that have been held. This is to be expected, considering the continuing growth of the association.

THIS year MODERN IRRIGATION is happy to play a small part in making the California convention a success and, in fact, will dedicate to the convention its October issue, in which will appear the first publication of WESTERN WATERWORKS, the new waterworks journal of the west. This number of MODERN IRRIGATION, too, will be the first **annual waterworks number** and will, from the standpoint of editorial content and advertising appeal, be especially edited for the waterworks executive and engineer. No pains are being spared to make this number a real, practical compendium of information, boiled down to give important facts, without extraneous matter; a sort of annual handbook for the western waterworks industry. With the usual features of interest to irrigationists and water developers in general, the number promises to be the most noteworthy that the publishers have issued.

That many an advertiser sees, in this special number, an opportunity to reach all branches of the hydraulics field in one medium is apparent from the response of those who sell either to the waterworks field exclusively or to the combined hydraulic industries of the west. The idea of WESTERN WATERWORKS—a magazine within a magazine—has apparently scored a bull's eye in filling a need long felt by the engineer and the advertiser alike. The advantage of a coverage of all phases of hydraulics in the one publication, for one subscription and at no increase in advertising rates, has its appeal to both.

The special October number will reach all of the regular subscribers in the hydraulics field and it will also be distributed at the convention at San Diego. The issue will carry all the pre-convention news and will be read on the spot, for the practical information it contains, by those attending the convention. The November number will have as wide an appeal because of the full accounts it will contain of the various papers to be read and a report of the transactions of the convention.

The convention number is to be an annual feature of MODERN IRRIGATION. It will be the one time in the year when the publication as a whole will have a predominating waterworks flavor, although the fact must not be lost sight of that each monthly issue will carry its quota of waterworks features and news items. Each issue will continue to constitute a "magazine of applied hydraulics" in every sense of the word.

Political Straws

THAT OBSERVER would be foolish indeed who would try to draw conclusive inferences from the recent primary election in California in relation to irrigation affairs. Although there were a number of issues involved in the major contests directly affecting the irrigationist, they were, after all, not the dominating issues of the campaign, and the outcome, in which the present governor of California was defeated in the contest for the Republican nomination for that office, was so close that it is impossible to say that the electors pronounced their will definitely or distinctly on any question of irrigation involved.

POINT *Of* VIEW

It is worthy of some attention, however, that Governor Richardson, the defeated candidate, was bitterly attacked by his opponents on the basis of his irrigation record, and in sections where irrigation is the life-blood of the country, notably in some sections of the San Joaquin Valley, the observer may easily read into the large majority accorded the governor's opponent a reflection of some dissatisfaction with the record of the present administration.

Another indictment brought against Governor Richardson was an accusation of costly economy in the matter of provision for forest protection. It is no secret that the champions of forest conservation have been far from happy at what they considered the insufficient state appropriations approved by the governor for forest protective work. Lieutenant-Governor Young, the governor's opponent, in his successful campaign for nomination, stressed the unwisdom and niggardliness of the administration's forest policy, and made definite promises of a more generous provision for this phase of the state's activities, if elected. If he becomes governor, as he will in all human probability, the advocates of reforestation and conservation will have a declared friend at the capitol.

Words, Idle Words

DIRECTORS of the Oakdale and South San Joaquin irrigation districts, in central California, ran across a problem the other day which stumped them more completely than many much weightier aspects of the great two-million-dollar job on which they are now engaged—the Melones dam. It seems that the dam, when finished, is to bear a nice bronze tablet, with an appropriate inscription. The representatives of the two directorates agreed upon a legend which seemed to fill the bill, and when they asked for an estimate of what the tablet would cost, they were surprised to find that the price would run around $250.

"Too much," said the conscientious directors. "The tax-payers of our districts don't mind paying what is necessary for irrigation water, but they won't stand a per-acre assessment for words. Let's see if we can't reduce the number of words on this tablet and thus cut down the cost."

But that wasn't so easy. The imperishable bronze is to bear the names of ten directors, the officials of the two districts, and the name of the company which is building the dam, and these things don't easily permit of abridgment or condensation.

Better pay the cost of the tablet, gentlemen, and have it in the form originally contemplated. The glory that a director of an irrigation district gets out of his job is brief and meagre enough. The Melones dam will continue to benefit the districts which it serves for many a year after that $250 is completely forgotten, and it will be a salutary thing for future generations to see, carved in the bronze tablets, the names of the men who gave their time and thought to its construction when it was only a vision, and who brought that vision into material reality.

Mexico and Irrigation

MEXICO is a land of contradictions in relation to irrigation, as to so many other things. In point of time, it is the cradle of irrigation on our continent, and, in the practice of irrigated agriculture, there are doubtless secrets that it might impart to its more advanced neighbors to the north. As an article elsewhere in this issue points out, however, it remains largely a country of undeveloped potentialities.

Depending to a large extent on irrigation for the successful practice of agriculture, it has, nevertheless, failed signally in those collective aspects of irrigation development in which the western United States has made its greatest record of achievement.

Whether the Calles government can work out a practicable reclamation policy under the terms of the law which is described by R. A. Hill, in this issue, is a question which can be answered only by Time. If the law is administered in the interest of the people for whom it has been ostensibly framed, in the light of the experiences of other governments which have learned costly lessons in large-scale attempts at reclamation and settlement, it may provide a basis for a workable system. If the Mexican government will be wise enough to draw upon the knowledge of the eminent engineers and reclamationists of the United States, as well as the best informed of their own countrymen, there may be hope for better things for irrigation in Mexico. If, however, a selfish policy of personal aggrandizement is to actuate those who administer the law, its failure will be inevitable no matter how sound its theoretical basis.

Just now, with a religious controversy raging in Mexico, the eyes of millions of people are turned in the direction of that little understood country. What the outcome of the present crisis may be, it is impossible to predict, but one effect, at least, may be to increase the popular interest in its economic, as well as its social possibilities. Irrigationists will find here a peculiarly fascinating subject. Many of the notable irrigation developments of the next fifty years will take place south of the Rio Grande.

Here is what irrigation has done to the desert in Nevada. Some conception of the growth of the crop may be obtained by comparing it to the figure in the foreground.

What Irrigation Has Done for My State--NEVADA

By JAMES GRAVES SCRUGHAM
Governor of Nevada

THE irrigated area in Nevada is about 560,000 acres. This is as compared with about 3,000,000 acres of lands in private ownership in this state. Of the 110,000 square miles in Nevada's boundaries *eight-ninths* is public domain, owned and in the keeping of all the people of the United States. In consequence, Nevada is largely dependent upon the care and control of the federal Department of the Interior, which supervises the public domain, including the lands useful for mining and, in part, grazing. The Department of Agriculture also controls in a measure the destiny of Nevada.

Federal reclamation and irrigation has been one of the most ambitious, constructive and beneficial enterprises of government ever carried out in the history of the nation. The era of interstate canals, interstate post roads and highways and of federal development of rivers and harbors, was a translation of the powers of the Constitution affecting interstate commerce and the promotion of the "general welfare." It was in pursuit of the latter principle as well as in discharge of its duty as conservator of the public domain, that the nation embarked on the project of reclaiming the arid lands that constituted a vast empire in the West.

Nevada had a distinguished share in the origin and history of this movement, for it was Senator Francis G. Newlands, now deceased, who gave the greatest impetus to the work. It was he who secured the appropriation of more than $90,000,000 as a revolving fund for the construction of irrigation projects, with the idea that the units would take care of themselves and finally return the invested capital so that it could roll on to other fields of construction. About 2,000,000 acres of new lands have been irrigated. A new farm population of about 142,000 has been created with 37,000 irrigated towns and the creation of about $600,000,000 new national wealth. Crops worth more than $100,000,000 annually are produced and about $200,000,000 has been expended in construction, of which about $60,000,000 has been repaid and replaced in the fund. The incidental prosperity and commerce arising from this production has been enormous.

Nevada has had her share of this development. The Truckee-Carson (now the Newlands) project, was the pioneer experiment in irrigation under national auspices. Naturally the government learned by the experiment in an engineering, social and financial way and, naturally, the settlers who first came to Nevada had the hard row to hoe. In consequence the Congress has recently charged off and relieved the settlers from a burden of about $5,000,000 of debt originally included in the construction and carrying charges. The waters supplied also fell short of those anticipated and the $7,000,000 originally expended was increased by $2,000,000 more for an added reservoir. The actually farmed area proved much less than that outlined in the beginning as feasible.

Irrigated lands in Nevada include:

	Acres
Humboldt river basin	198,000
Truckee river basin	20,000
Carson river basin	71,000
Walker river basin	113,000
Central interior basin	66,700
Colorado river basin	8,500
Snake river basin	83,800

These districts not only use most of the surface run-off but have use of reservoirs impounding an aggregate of about 500,000 acre-feet of water.

In 1904 the area that would be reclaimed in the Truckee-Carson project was estimated at 210,000 acres. At present the actual irrigable area is 73,302 acres and the ultimate irrigable area is 97,400 acres. At present only 61 per cent of the irrigable land on the project is farmed. The crop value in 1924 was $1,405,120. or $34.47 per acre. There were 762 irrigated farms and a population of 2,668 including 5 towns with a population of 2,300, 11 school districts, 9 churches, one bank with 1,700 depositors, 25 new settlers coming in and 10 old settlers going out.

It will be seen that irrigation under government auspices has not been a striking social phenomenon in Nevada, but the outlook is hopeful. Congress has authorized an additional project, the Spanish Springs unit of the Newlands project, and plans are making for a project in Carson Valley and on the Humboldt River. The figures here, while intrinsically small, are large in proportion to the state's life. The total products of the livestock and agricultural industry on the one hand and the mining industry on the other are less than $30,000,000 annually. The projects anchor people in communities, and in addition to the raising of alfalfa, potatoes and other crops such as sugar beets, there is a nucleus of a valuable dairy industry.

J. H. Cox is New President of Irrigation Equipment Group

Zimansky Closes Successful Year With Annual Meeting at Sacramento

A MODERN IRRIGATION STAFF REPORT

JOSEPH H. COX will guide the destinies of the Western Irrigation Equipment Association during the year that lies just ahead, as the result of the election held at the annual meeting, in the Sacramento, Cal., Fair Grounds, on September 8.

On the "Cox for President" ticket, as submitted by the executive committee and unanimously passed by the members present, there were included the names of J. E. Lundy, vice-president; C. A. Utley, secretary, and J. J. Merritt, treasurer. The three other members of the executive committee will be R. R. Van Ness, D. Stevenson and W. R. Mongerson.

Retiring president Zimansky opened the meeting with some twenty-five members present. Various communications were read by secretary Utley, and the report of the treasurer was heard and approved.

Last of the Pump Tent

J. J. Merritt and Professor Fletcher announced there is every reason to hope that, by the time the 1927 California State Fair is opened, the pump exhibits will be housed in a permanent building instead of the old familiar pump tent.

R. R. Van Ness, who has labored industriously on the problems of smoothing out the well drillers' difficulties with the California State Motor Vehicle Act, reported that he had had several conferences with representatives of the general contractors, machinery and equipment dealers, and highway development associations. It has developed that the same rules of the state highway officials that bid fair to work a hardship on the well drillers are causing considerable concern to members of the other organizations named. Mr. Van Ness will continue as chairman of the committee with the likelihood that all of the agencies interested will cooperate with the W.I.E.A. in presenting an amendment to the Motor Vehicle Act for the consideration of the next legislature.

Professor Moses advised the meeting that the uniform contract for pump installations has finally been completed and will soon be presented for adoption to the agencies interested, namely, the Western Irrigation Equipment Association, the Pacific Hydraulic Engineering Association, the California Committee on the Relation of Electricity to Agriculture, and the Federated Farm Bureaus.

Cost Details Worked Out

The final wrinkle to be ironed out, so that the plan will be fair to both buyer and seller of pumping equipment, was in the matter of the details and costs of the tests. As the arrangement now stands two tests will be available, the buyer having the option of taking one or both or neither. A prospective purchaser of a pump may have a manufacturer's test made before he purchases, paying for it at the rate of $1 per rated H. P., the minimum charge being $20. After the installation, and within a certain stated period, the purchaser may have another test made. If this test discloses that the pump is performing according to the maker's rating, the cost of the test will be borne by the purchaser; but if it develops that the pump is not delivering the flow in the warranty, the cost will be borne by the seller.

C. B. Noyes, who serves as chairman on the publicity committee, submitted a suggestion for a new W. I. E. A. membership seal and official "trade mark" of the organization. Mr. Noyes urged that some sort of device be adopted at an early date, that all members be requested to use it in all advertising and on their stationery. A call has been issued for ideas as to the proper design, these to be submitted to Secretary Utley, who will in turn hand them over to the publicity committee.

Zimansky Relinquishes Gavel

President Zimansky reported that the pump data book has been completely revised, and will be handed to the printer as soon as the members of the association send in their proper addresses and the names of the present officers of their respective companies. It was decided at a previous meeting to incorporate this information in the new data book.

In his retiring address Mr. Zimansky summed up the work of the association after five years of organization. Dealing with equal frankness in discussing shortcomings as well as accomplishments, he sketched the future possibilities of organized effort in the light of past accomplishments, bespeaking for the incoming officers the tireless and loyal support of the membership.

JOSEPH H. COX

The date of the next meeting was set for November 19 at San Jose.

Auburn Has Model System

Auburn, Washington, claims one of the finest water systems for a city of five thousand people that can be found anywhere on the Pacific Coast. This summer the Auburn people celebrated the completion of the new water project for which they had voted $200,000 bonds. The water comes from the Coal creek springs, about four miles away by pipe, near the White river on the east side of the valley.

Equipment has been installed for piping approximately 8,000,000 gallons a day. A dam which has formed a large impounding basin has been thrown across the stream and the water is diverted into a large 24-inch wood stave pipe line. About three-fourths of the water is used to operate the three Hill hydraulic rams. The reservoir is of 3,000,000 gallon capacity and is approximately 200 feet higher in elevation than the city. An adequate system of pipe lines for present needs has been laid and valves, crosses and tees have been installed so that additional lines may be laid to other sections of the city as the demand for water in these districts requires.

Another important product of the irrigated farm. Part of a prize herd on the Delhi (California) settlement.

The Farm Tenancy Question

(*Continued from Page 15*)

farms would be operated by tenants. Moreover, the young man would have the guidance of the landlord father in steadying him during his apprenticeship.

Actually, we have other conditions entering in, some of which have been mentioned above. In the country as a whole, tenancy is undoubtedly to a large extent a stepping stone to ownership. Whether this is generally true in the irrigated west, it is hard to say. Observation leads one to think that in many cases it is, although a recent study indicates that no such condition exists in California. The study referred to is that made by a committee of the Commonwealth Club of California under the chairmanship of Professor R. L. Adams, of the University of California.*

Two criticisms that have been levelled at tenancy here and elsewhere are that the tenant is likely to abuse the farm and that the absentee landlord may not adequately equip it. Two suggested remedies may be mentioned. One is that a long lease be employed so that the tenant may safely make improvements without fear of having the rent raised. A second suggestion is that the tenant be protected against an unscrupulous landlord by some such arrangement as is in use in England.

It might be pointed out that the long lease alone will hardly solve the problem. In any new country—and that applies to all our western states—particularly where conditions are rapidly changing, few tenants care to bind themselves with long leases. Even in an older country this has not always proved satisfactory. In England, at the beginning of the last century, long leases prevailed, but the fluctuations in price resulting from the Napoleonic wars brought them into disfavor with both landlords and tenants, so that by 1850 short leases again came to prevail. Since that time an elaborate scheme has been developed for protecting the tenant.

Under the English Agricultural Holdings Act of 1923, improvements are divided into three main groups and different rules are applied to each. The three groups and the rules applying to each are briefly as follows:

Group I, in which written consent of the landlord is required if the tenant is to obtain reimbursement for unexhausted improvements upon leaving. This includes such permanent improvements as the erection or alteration of buildings, the erection of silos, the laying down of permanent pastures, the making of improvements on roads or bridges, the making or removal of permanent fences, the reclaiming of waste lands, and similar activities.

Group II, in which notice to the landlord is required, but consent is not necessary, includes only drainage.

Group III, in which neither notice to nor consent of the landlord is required, includes the liming of land, application to the land of purchased manure or fertilizer, benefits to the land from the feeding thereon of cattle, sheep, pigs or of horses other than those used regularly on the farm, the laying down of temporary pastures, and necessary repairs other than those the tenant is under obligations to make, etc.

An elaborate system of evaluation has been developed and a large corps of appraisers has been trained in order to facilitate the frequent settlement of disputes on a scientific basis as farmers move from one holding to another.

Whether such a scheme is feasible or desirable in the United States may be a matter for debate. We do, however, need a clearer recognition of the facts that (1) tenancy is undoubtedly here to stay, and (2) our laws and our practices should be such as will develop our tenancy system so that it will permit such utilization of land as may be demanded by national welfare, whether considered from the economic or the social viewpoint.

*(See Transactions of the Commonwealth Club of California 17: 399-448. November 1922, and California Experiment Station Circular 272: 2-48. November 1923).

Irrigation Practice in Mexico

(*Continued from Page 13*)

Mexico have been the result of the peculiarities of climate and of the character of the works which have been constructed. Practically no rivers of Mexico are supplied from melting snow, consequently they are subject to wide fluctuations, coincident with the occurrence of rain.

The irrigation systems have in general been built by individuals for the irrigation of their own land holdings. There are few cases of large distribution systems serving groups of owners and almost no examples of storage regulation for irrigation.

Employ Bolsa Method

The common system of irrigation, therefore, has been by the *bolsa* method, similar to the system of flooding much used in California in the latter part of the 19th century, and still practiced to some extent. High borders are built around each field, water is admitted into the basins thus formed, and allowed to stand until absorbed by the soil or evaporated. Frequently only a single irrigation is possible, although this may be more than two feet in depth.

Until the streams are regulated by the construction of reservoirs this method of irrigation will undoubtedly remain customary, except along the east coast where the flow of the rivers is more uniform.

There are some projects, however, which are being developed along modern lines, particularly those where only a small portion of the ultimate area is now irrigated. On the Yaqui River, for example, approximately 100,000 acres are being irrigated in accordance with the most modern practice by direct diversion from the river. Further expansion of this project, however, is entirely dependent upon stream regulation. The same condition prevails along the Fuerte river in the vicinity of Los Mochis.

Success Lies in Future

The success of modern irrigation in Mexico cannot be determined for many years. Undoubtedly some projects will be constructed which will not be found worthy and the cost of development will in many cases greatly exceed the amount now considered as necessary.

There is little accurate data available as to the amount of water which can be supplied to the lands in the various river valleys. As irrigation has heretofore been almost entirely from unregulated streams, and as few works of great magnitude have been constructed, there is little experience to guide investigators in their determination of the needs of any region, and of the cost of development to supply those needs.

The agricultural products from new irrigation projects will be absorbed to a large degree by the people of Mexico itself. Surprising as it may seem, Mexico is a food importing country, although its population is only about 15,000,000 and its area 760,000 square miles. This situation is due, not to lack of productivity, but largely to transportation limitations. A large percentage of the people live on the Mesa Central, which agriculturally is of secondary importance. The productive agricultural regions along the coast are in a large measure isolated from the interior. Improved transportation, therefore, will provide in a large measure the market for the agricultural products of these new projects.

The future of irrigation development in Mexico is fundamentally dependent upon the degree and effectiveness of colonization. The Mexican Indians who comprise the bulk of the population, are not by nature farmers in a modern sense of the word. It is expected that much of this land will be developed by selected immigrants from those European countries which are fundamentally agricultural.

The most striking phase in the irrigation development of Mexico is the avowed intention of the Government, as testified by its chief executive, that this development shall be sanely and economically carried out, and that everything shall be on the basis of "pay as you go."

LAYNE & BOWLER PUMPS

LAYKOLD
EMULSIFIED ASPHALT

ASPHALTIC concrete ditch linings are superior to other types of linings because they are flexible and hence conform at all times to the shape of the bank without opening cracks. If the ditch bank settles, so does the asphalt lining but there is no loss of water. By carefully controlling the weeds with our weed killer, there will be no future trouble from that source, Laykold linings are handled cold, the same as cement concrete, but are flexible.

THE HYDRAULIC DIGEST

A Monthly Bulletin Board of Brief Facts and Events from Far and Near

Tacoma Plans New Reservoir

Tacoma, Washington, has awarded the contract for constructing a 25,000,000-gallon reservoir for the city water department. Construction is to be completed by April 1, 1927, so that relief may be given next summer.

Irrigated Farms Total 35,000

There were on June 30 a total of 35,000 irrigated farms in the United States, with a total population of 137,000, or an average of a little less than four persons to a farm, according to figures recently compiled by the Bureau of Reclamation.

Phoenix Extends Water System

Phoenix, Arizona, has awarded the contract for the installation of and material for the extension of the city's water system to Fisher & McCall. The sewer lines will be laid by Schmidt and Hitchcock, of Phoenix, with material furnished by the Arizona Concrete Pipe Co. The gross cost will approximate $360,000, secured by recent bond issue.

Water System Adds New Well

The Spring Hill Water Company, of Bothell, Washington, has recently drilled a new well to add to the city water supply. On a four-hour test it furnished over 5,000 gallons an hour, an amount greater than is considered necessary for the city's needs. There has been a critical shortage of water in Bothell this summer and the company has made every effort to prevent similar trouble in the future.

Fixes Spraying Charge

The city council of Long Beach, California, has adopted a new policy in regard to sale of city water to ranchers for spraying. City Engineer Fred C. Froehde pointed out that, under the arrangement that has been in force, the ranchers were ruining the fire hydrants by using Stillson wrenches on them. After lengthy discussion the council voted to make a charge of 50 cents per acre sprayed inside the city and $1.00 per acre outside the city. This rate is to go into effect Oct. 1, when the city takes over the properties and rights of the Consolidated Water Company.

Laguna System Ready Soon

Steps for the completion of the $600,000 water system being installed at Laguna Beach, California, were taken when the water board recently called for bids on the main line to be laid from the Santa Ana River basin to Laguna Beach, a distance of about fourteen miles. The work, according to the engineer's estimates, will cost about $240,000. More than $380,000 has already been spent in the district in piping water to the houses and in laying mains throughout the city.

Organize Water Company

The Port Costa Water Corporation, announcing headquarters as San Francisco, recently filed papers with the Secretary of State. The corporation, which announced plans to construct water works, pumping plants, reservoirs, and other appurtenances to the water supply business, was organized by Allen L. Chickering of Piedmont, H. T. Beverly of Oakland, and A. Demartini, D. M. Gregory, Vincent I. Campagno, W. C. Fox, and A. E. Porter, all of San Francisco.

Dry Season Teaches Lesson

The board of directors of the Central Oregon Irrigation District has been investigating the cost of securing the storage of Crane Prairie. The North Canal Company offered to sell all of its rights to this storage, the diversion dam and all of its property for $50,000, but the board considered the price too high and turned down the proposition. Several speakers at the meeting voiced the opinion that a season such as this was a valuable lesson to irrigators, teaching them to take care of the water they received.

Water Bonds Get Big Majority

By an overwhelming vote the residents of Brentwood, California, have established the first Contra Costa County water district to serve the town with a domestic water supply. One hundred and one out of 107 total votes cast were in favor of a $20,000 bond issue to purchase existing equipment, install complete fire protection, and develop new wells for local supply. This step will assure the immediate construction of a number of houses which have been delayed for lack of adequate water supply and fire protection.

Snohomish Wants More Water

Snohomish, Washington, has suffered such extreme water shortage this summer that the city council has taken steps toward increasing the capacity of the pipe lines. A firm of Seattle hydraulic engineers recommended to the council the installation of four miles of 20-inch pipe from Gemmer hill to the dam, which impounds the city's water supply, and the construction of a new dam, or the installation of a pump at the present intake to increase the flow. It is estimated that the dam would increase the flow 500,000 gallons a day, and the pump 300,000. The cost of the dam has been estimated at $17,600, the pump at $6,000, and the pipe line $76,000. Councilman Bakeman, head of the water committee, stated that the demand was almost double the supply. He has urged the installation of meters, but that plan has not met with favor.

Rockwood Wants Water Now

Whether to dig wells or suffer a long thirst until next spring is a question that will have to be decided by the Rockwood water district (Oregon). A committee was recently sent to confer with John M. Mann, commissioner of public utilities, on the prospects of getting Bull Run water immediately. Commissioner Mann told the delegation that as soon as the Bear Creek dam is completed there will be plenty of water, and the district can have all it wants. If there is a hard winter and plenty of snow, Rockwood will be able to get the connection in the spring. "The people voted $72,000 to lay mains and make the connections with Bull Run water," said the delegation, "and they want the water now. We must have water or the people will not stay there." They declared their readiness to install a 200,000-gallon tank to hold a three-day supply, and to meet every city regulation.

Lindsay Goes It Wholesale

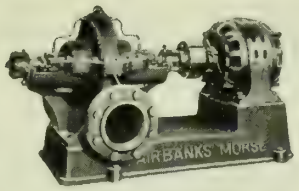
By way of expressing their conviction that the states' needs are the needs of the San Joaquin Valley, the directors of the Lindsay, California, Chamber of Commerce recently took out a blanket membership for their 300 members in the California State Irrigation Association. The action of the Chamber of Commerce follows that of the Lindsay Farm Center, which recently took out a blanket membership for its 240 members. The chamber also appointed a committee to work with H. E. Martin, of Tulare, campaign manager of the association, in a canvass of business organizations in the community to get them to take similar action. Mr. Martin says that the association is squarely behind the plan of the state engineering department to bring the flood waters of the Sacramento river into the San Joaquin Valley for irrigation purposes. The state engineering department, under the leadership of Paul Bailey, has been working on the plan for some time and has indicated that it has been found feasible from an engineering standpoint and that the cost would not be excessive. Mr. Martin states that if the valley can present a united front the plan will receive favorable consideration in the next legislature and the water problems of the valley will be solved.

Will Vote on Water Bonds

Chowchilla, Madera County, California, is to vote this month on the proposed $25,000 bond issue for the purchase and improvement of the local domestic water system. Under the plan to be submitted to the voters, either the old system will be purchased and repaired, or an entirely new system installed. According to B. O. Weber, city engineer, the present system can be purchased for $17,500, and improvements which would care for the city's needs for the next 25 years could be made for the remainder of the $25,000. Replacement of the present system would cost about $30,000. The present system was installed in 1912 and includes 20,000 feet of lines.

Plans Big Reservoir

Forecasting immediate construction of a storage reservoir in the Deschutes Basin (Oregon) which will be one of the largest in the state, the Arnold Ditch Company has filed on the entire run-off for storage of the Big Marsh watershed. Big Marsh is a depression similar to Odell and Crescent lakes. A dam thrown across the outlet, or at some point in Big Marsh creek below the outlet, will convert this marsh into a big lake, holding the winter run-off from the high Cascade country. The available storage is 38,000 feet.



Built for your needs

The pumping unit illustrated is typical of the finely built Fairbanks-Morse Units that have become so popular where crops depend on the reliability of the pump. Both motor and pump are built by Fairbanks-Morse. The rugged pump, carefully constructed of the finest materials and thoroughly tested before shipment, is direct-driven by the famous F-M Ball-Bearing Motor—a motor with an unchallenged reputation for dependability.

With this unit, lubrication is reduced to a simple operation of greasing the bearings once in six months—in many cases greasing only once a year is required. Bearings throughout are ball bearings. Journal wear is eliminated; vibration is prevented; a precise running clearance is maintained between wearing rings and impeller—pump-life is lengthened.

Other pumps of a wide variety of types; ball-bearing motors for horizontal and vertical drive; Diesel engines for low cost power on isolated locations are included in the comprehensive Fairbanks-Morse line of irrigation equipment.

MANAGEMENT

Lateral Maintenance---Always a Tough Management Problem---Is Well Handled Here

By FRANK FYFE,
*President Sunnyside Irrigation District**

FROM the very beginning of reclamation work, the problem of maintenance of laterals has continually impressed itself upon the organizations in charge. Unfortunately, a great many people harbored the erroneous idea, that when the construction was completed, the next step would be to turn in the water, and it would be at their service for all time without further cost or effort. The fallacy of this idea was forcibly impressed when it was found that new laterals were subject to breaks during the first few years of their use. The banks being amply supplied with water, furnished an ideal place for a profuse growth of grass, weeds, etc., which fell over into the laterals, and not only greatly retarded the flow of water, but impregnated the surrounding lands with a surplus of moisture, causing them to become alkalied or water logged, and in many instances the lands became valueless.

It soon became apparent to the organizations delivering water, that the time would come when the cost of operating and maintaining of laterals would be in excess of their original estimate.

Later, the United States Reclamation Service took over the works of the Sunnyside Division of the Yakima Project, and assumed all of the obligations necessary for the operating and maintaining of the system down to 10 c. f. s.

Cumbersome Arrangement

After the Government had assumed control of the Yakima Project, it soon became apparent that direct dealings between the Government and individual water users were too cumbersome. It necessitated too much detail work from the Washington Office with each individual water user. Consequently, water users' associations and irrigation districts were formed to act as intermediaries.

*A paper read before the Thirteenth Annual Meeting, Washington Irrigation Institute, Yakima, Wash.

Back in 1922

When Frank Fyfe first became a director of the Sunnyside Valley Irrigation District in Washington the work of lateral maintenance was divided into 49 maintenance districts and carried on by the district crews and Reclamation Maintenance crews. The method was impractical and the cost too high—96 cents an acre. Mr. Fyfe suggested the unique idea of selecting a foreman in each district from among the water users in that district, who should call out the men of his district to care for the laterals, thus localizing the work and expense, and eliminating the cost of time and conveyance in going to and from work. The plan did not meet with much enthusiasm, but the directors finally agreed to give it a trial. And now, four years later, the success of the plan has been fully realized. There are now 74 maintenance districts instead of 49; and the average cost per acre last year was 48 cents as against 96 cents under the original plan. The plan itself, involving as it does many individuals of unlike character and disposition, would be doomed to failure if it were void of that one great principle so necessary to all organizations where interests are mutual—cooperation.

One of the purposes of the Irrigation District was to cooperate with both the Reclamation Service and the water users. The Reclamation Service operates and delivers the water to all farm units and does the maintenance work on all main and branch canals down to the ten second foot point. And from this point on the maintenance is left to the care of the water users to get along the best way they can. If the laterals are small, they can get along very well by just turning out and each doing his share of the work. But on the larger laterals it is very different. There are many non-resident owners that have renters on their farms, and most of them do not help with the cleaning of laterals or help with the expense of repairing the flumes or pipe lines. They, of course, feel their landlord should stand any expense of getting the water to the land. Then, there are always some of the land owners that are very busy at lateral cleaning time, and cannot get out to do their share, so it quite often falls on a few to get out and do the work.

Collection Method Devised

The officials of the Sunnyside Valley Irrigation District benefited by the experience of the Sunnyside Water Users' Association, realized that there would be an expense attached to the care of laterals, and that an insured method of collection was necessary. Accordingly, by-laws were passed authorizing a hearing on a petition for the formation of a maintenance district on any lateral when such petition is accompanied by signers holding at least twenty-five per cent of the acreage.

When the writer became director of the Sunnyside Valley Irrigation District in 1922, forty-nine of these districts had been formed, and the work had all been done by Sunnyside Valley Irrigation District crews and by Reclamation maintenance crews. This method was impracticable. The expense was too high, costing on an average of 96c per acre. The directors were besieged by the water users from all sides. Many urged disorganization of the districts. It was apparent that a change was necessary. Something had to be done. The writer, a new member of the Board, suggested a change whereby a foreman should be selected in each district from among the water users of that district, who should call out the men of that district to care for the laterals, thus localizing the work and expense and eliminating the cost of time and conveyance in going to and from the work. Like all new ventures, this was not graciously received at first. It was thought impossible to get foremen who could efficiently maintain the laterals. However, no good cause is ever won in a single day, and, after continued effort and insistence, it was decided to give the plan a trial.

The success of the plan as outlined has been fully realized and these forty-nine districts have grown until they now number seventy-four, and we have two petitions out for signatures at the present time. Out of the seventy-four thus formed only two disorganizations have been effected. From the forty-nine districts organized and operated under the original plan and comprising 24,369.17 acres, we have grown to the seventy-four districts under the present plan with a total of 31,810.84 acres. The average cost per acre under the present plan for last year was 48c, as against 96c per acre under the original plan.

What the Colleges Are Doing

(*Continued from Page 17*)

answer many of the questions of immediate concern to the irrigator.

Changes Taking Place

Within the past five years the general character of these investigations has undergone a decided change. In a comprehensive study of the economic use of irrigation water there are certain basic principles governing the use of water by plants and the movement of water through soils. In order to obtain more definite knowledge of these principles and laws, several of the colleges are making an intensive study of these basic principles. By growing deciduous trees and field crops in large tanks, insofar as possible under controlled conditions of soil moisture, the rate of extraction of moisture by the plant, the relation between rate of loss and the existing moisture content of the soil, and the point in moisture content at which the plants or trees wilt in the various soil types may be observed.

This work is extended into field plots, where, by means of intensive soil sampling, the results obtained from tanks may be verified or disproved, and in addition to this, determinations are made of the depth of moisture penetration resulting from varying depths of water and applied. Such tests include, also, observations of the rate of moisture loss following irrigation, the depths from which moisture is being taken from the soil, the effect of cultivation in moisture conservation and as an aid in absorption of irrigation water by the soil. The results obtained are correlated with crop yields, rate of growth, time of maturity of the crop, and so forth.

Commercial Tests Sought

Further extension of these intensive studies is being extensively made in commercial fields to determine the consumptive use of water—that is, the to-

tal amount of water in acre-feet, including evaporation from the soil surface, being taken from the soil in the production of commercially grown crops. This work is carried on in carefully selected areas representative of standard practice in crop production and irrigation. The total quantities of water applied to the field as a whole and to the selected plots within the field are carefully measured. In the areas selected for intensive studies, a thorough sampling of the soil for moisture content is made before and after each irrigation, showing the available moisture in the soil at the time of irrigation; the depth of penetration and the distribution of the water applied; the efficiency of the irrigation in per cent of soil mass which actually has been moistened, the rate of extraction and depths from which water is taken from the soil and finally the total seasonal use of water by the plants.

The information thus obtained, when properly interpreted, should form a basis for more efficient irrigation practice, giving the irrigator definite data concerning the seasonal water requirement of the crop in question, as well as furnishing data concerning the desirable frequency of irrigation and depths of water to be applied at each irrigation on the various soil types.

Field Observations Vital

By means of field observations, various phases of methods of irrigation and preparation of land are being studied by a number of the agricultural colleges. It is recognized without question that the character of the crop grown, the extent of the water supply, the method of water delivery, the topography of the land, and the soil type are all factors which influence the proper method of land preparation and irrigation.

As the necessity for a more economical use of the irrigation supply becomes apparent, the irrigator is going to ask for additional information on the method by which the greatest efficiency may be obtained under a given set of field conditions. Such questions as the efficiency and adaptability of spray irrigation for orchard and truck crops, contour planting and terracing as an aid in efficient irrigation, furrow vs. flooding in orchard irrigation, desirable width and grades in border irrigation, are of growing importance.

The author has, within the past few months, heard the statement made by several citrus growers of Southern California that their most serious irrigation problem in the future will be the difficulty of obtaining a desirable penetration of irrigation water into the soil. Observations recently made in a mature citrus grove showed that in certain portions of the grove a moisture penetration of less than 3 inches below the bottom of the furrow was obtained as a result of an eight-hour application of water. The question the grower asks is: Can this condition be remedied through a change in the method of irrigation and could it have been avoided? If problems such as this are of increasing importance, the colleges of agriculture, with the information now at hand, plus that now being obtained through systematic investigations and observations, should be able to render valuable assistance to the irrigator.

The problem of waste of water on the farm, either in transportation or application, together with methods of preventing such loss, is one upon which much information is available. Manufacturers of irrigation equipment are meeting the demands of the water user for higher efficiencies and longer life in pumping machinery, improved quality in concrete pipe and other types of conduits, and improved design in water regulating equipment. As the value of irrigation water increases, the demand for standardization of the methods of water measurement under varying conditions of flow will increase. Several of the colleges have interested themselves in this phase of the work.

Answer Definite Need

The Colorado Experiment Station, in its co-operation with the Irrigation Investigations of the U. S. Department of Agriculture in the development of the Venturi flume for the measurement of water flowing in open channels, under sand and silt conditions, furnishes an excellent example of what is being done to meet the demand of the irrigator for a practical method of water measurement under unusual conditions. Other colleges have equipped or are equipping themselves with various types of hydraulic or field laboratories, principally for the testing of water measuring devices and for determining the efficiency of various types of irrigation equipment used on the farm.

It is hard to realize that in California alone there are being commercially grown under irrigation more than one hundred and fifty different crops at elevations ranging from below sea level in the Imperial Valley to 3000 feet above sea level in the interior mountain valleys, with soil types ranging from the coarse gravels of the old river channels to the heavy impervious clays adapted to rice production. With this wide range of crops, climatic conditions and soil types, each soil type demanding special consideration in its preparation, method, time and depth of irrigation, and each crop with its individual water requirement, it may easily be seen that no matter how efficiently the irrigation work of the colleges is organized, they can scarcely hope to meet fully the continuously growing demand for information on the many phases connected with the economic use of water in irrigation practice.

Feasible or Not—How to Decide

(*Continued from Page 11*)

irrigation agriculture *can* be made permanent.

Economic considerations such as location, marketing institutions, and transportation, vitally affect the earning power and cost of production. The cost of agricultural development is an important factor in irrigation economics. The cost of development and of production may be decreased by scientific agricultural methods.

The ability and experience of the individual farmer in irrigation agriculture is a very important factor in profitable cropping. Conditions should be made such as will attract the experienced irrigation farmer, and only where these are promising will he be induced to settle on raw land.

The interest charge of undeveloped land on a project is a serious handicap. We have been encouraged too much by financing agencies to develop large projects and have not been encouraged sufficiently in culling out severely, so that only the best land should be included for improvement. Every undeveloped acre adds a double burden on the developed acre. Lands that will not be improved and working in a few years after a project is financed are liable to come to the district for taxes and had better be eliminated in the beginning, so that a smaller project can be initiated at less cost. It is a fallacy and an illusion to increase the total acreage of a project by including poor land, particularly in an irrigation district where all must "hold the sack" together.

The plan of fixing water charges according to the probable producing power of the land has been recommended for ten years and fortunately it has been adopted by the Reclamation Bureau as a result of the recommendations of the Fact Finders Commission. This gives a better distribution of the fixed charges for reclamation according to ability to pay. Districts should have a revolving fund to level, seed and resell lands received through delinquent payments. Contracts providing that half the increase in value due to the coming

of irrigation from raw land sales should go to the district will provide such a fund. Too early bond maturity is a common source of difficulty.

Credit Facilities Important

It has been estimated on several proposed federal projects that something like $7,000 or $8,000 would be required to bring a farm unit from sagebrush into full production, provide implements, stock, shelter, fences, and to clear and fit the land for crops. Agricultural credit facilities will be a determining factor in the feasibility of numerous new projects. The settler should have capital or equipment amounting to half of the capital required to develop a farm unit, but better agencies and methods for financing, to meet the balance of the capital need, must be developed. Water gives added value to arid land only if the lands are fitted and farmed. Raw lands in private holdings should be disposed of in suitable farm units at a minimum price to actual settlers.

Water rights and land titles should be clear and the water supply sufficient to meet irrigation requirements for suitable crops and types of farming. A project permitting sufficient water for straight alfalfa growing would not be considered a good project from an economic standpoint. The erroneous opinion is prevalent among irrigators that their water charges are not affected by the amount of water they use.

Crop rotation or use of an inexpensive fertilizer may increase the returns per unit of water and land and have a beneficial effect on productive value of land and water.

A planned program of land settlement by the organized colonization method will hasten the rate of settlement and shorten the time required to bring farm units to a condition of profitable production. It is believed advisable to fit a part of each farm unit and seed to a perennial crop like alfalfa. New settlers should be encouraged to invest as far as possible in growing crops or "live stock" and hold his investment in "dead stock" or building equipment to the least necessity during the first years. The Durham Colony, in Northern California, established in 1917, included 6,000 acres. It was put on the market in 1918 and by September, 1922, all the farms had been sold, and practically all the land was in either crops or pastures within five years from time of purchase. For projects of 10,000 acres and more, census figures show 66 per cent improved when these projects are 20 years old. These demonstrations point the way for private enterprises, as well as possible federal reclamation activities.

Cost of applying the water in the field must be included in the cost of production to be met before a margin of profit can be realized. The annual cost of water to irrigators, as well as the crop value, will affect that margin of profit. The main factors determining the annual cost of water to irrigators in reclamation districts are: 1—The district tax, (including bond interest, bond principal; the general fund for rentals, improvement, power, operation, and maintenance, and general administration); 2—The duty of water; 3—The interest on the capital invested by the farmer in addition to that of the district.

Good management of the project is important to keep the costs to a minimum. The annual cost of irrigation is increased for storing and delivering a larger quantity of water where a large amount is used per acre. Where this is used, it is especially costly on pumping projects, or where it causes alkali and drainage problems.

Other Factors to Study

Other factors affecting the economic value of land and water should be studied, including the existing indebtedness of a community and of its individuals, land ownership, and tax rate present and prospective. We should plan our reclamation program on a business basis and look ahead for a decade. We must look beyond the time when water is brought in and the land is sold off in farm units. We must consider the ability of the settler to meet his payments the third year, the fifth year, and every year, and until the project is brought into full production.

Immigration and increase in population may affect the economic feasibility of a project. National financial conditions and economic cycles will also have their effect. We should work for a national reclamation program that will ultimately utilize the water resources of the West and of the nation. The good land that can be added to the improved farm land by irrigation is no more than that of a single state, like Illinois, and this will all come to be needed, if this nation is to continue to produce its foodstuffs.

As a final illustration, I refer again to the soil. Soil may be uniform or it may have two or three layers or horizons in its profile. Likewise we may have one-, two-, or three-story men. The one-story man deals in facts, the two-story man plans and reasons with the facts, and there are some three-story men—men with a skylight, who, working in harmony with the great Architect of the universe, imagine, postulate, and create new concepts, and such men are needed to envision, create, and perfect the reclamation of our arid lands.

Marin County Job is "Crookedest" Pipe Line; Has Many Unusual Construction Features

By H. ELLIOTT TAYLOR

GET out all the old familiar comparisons that are used to express the superlative of crookedness—the corkscrew simile, the snake's-back metaphor, and all the rest—add a few original figures of speech from your own vocabulary, and you still will have done less than justice to that certain welded steel pipe line now under construction in Marin County, California, for the Marin Municipal Water District, of San Rafael.

And, in case Marin County is an unfamiliar port of call in your itinerary, it may be well to recall to your mind that that picturesque peninsula which forms one protecting arm between the Bay of San Francisco and the Pacific Ocean, extending down from northern California and almost meeting the San Francisco peninsula at the Golden Gate, is the seat of "Marvelous Marin"—so called by its loyal and patriotic residents, and not to be confused with the Marvelous Morons which are more common and not nearly so attractive upon long acquaintance.

The principal communities of this peninsula are San Rafael, San Anselmo, Fairfax, Ross, Kentfield, Larkspur, Corte Madera, Mill Valley, Belvedere, and Sausalito, and these are the towns, as well, that are served by the Marin Municipal Water District. Practically the entire southern end of the county will be benefited by the improvements now being undertaken by the district.

The crookedest pipe line, welded and ready for lowering into trench.

An Unusual Construction Job

The pipe line which is being built for this district is not only the ultimate in crookedness, however. It is, in many of its construction features, one of the most interesting examples ever afforded in the hydraulic industry of the possibilities of a welded steel line.

Formed in 1912, the Marin Municipal District represented a project the original cost of which was something more than $3,000,000. Several years were consumed in the necessary preliminaries of organization, including the voting of bonds, condemnation proceedings, and the purchase of the properties of the then existing water companies; and actual operation of the district as a distributor of water began in November, 1916.

Improvements since that date have added steadily to the value of the property and its usefulness to those it serves. The contract for the district's Alpine dam was let in June, 1917, and by January of the next year the structure was completed. In 1920 the district voted a second bond issue of $500,000 for improvements in the distributing system,

LEFT: Lowering a section of the welded line into the trench prepared to receive it, by means of the portable adjustable lowering device. RIGHT: The widest place in the entire bench—and no room to spare, at that. Note the winding course of the line as it skirts the mountain-side.

Where the new line ties in with the tunnel.

and in October, 1925, another and larger issue—this time for $1,500,000—was passed, to care for extensive improvements and enlargements made necessary by a constantly increasing demand for water. Under the terms of this issue, the steel transmission line is being laid.

The design of the Alpine dam (1917) is full gravity section, curved in plan, the radius of the upstream curve being 465 feet. The original height of the dam was 100 feet above stream bed, elevation 515 feet. The crest measures 325 feet, its thickness at the base is 78 feet, and the overflow is cared for by six siphon spillways.

In 1923 an addition to the dam raised it to its present height of 108 feet, which increased the storage capacity from 1,000,000,000 gallons to 1,500,000,000 gallons. At this time, also, sluice gates especially designed for the purpose were placed over the mouths of the spillways so that the water level can be maintained at any desired height between the crest of the spillway and the top of the dam. The normal rainfall over the 10,450 acres of watershed lands owned by the district is 56 inches annually. When the 6,000 additional acres now under condemnation proceedings have been acquired, and the necessary storage facilities have been provided, Marin County will have little reason to fear for a water shortage. A normal supply of about 35 million gallons per day will be provided when these plans are brought to fruition, while the present peak consumption of the district amounts only to 6.5 million gallons per day.

Big Work Going Forward

The new welded steel transmission line, is the theme of this article, and the foregoing is a digression—material, however, to understanding of the problems and status of the district. The new line is the first improvement to be undertaken under the most recent bond issue.

The original transmission line, from Alpine dam to the Phoenix gate house, the point of distribution to the various balancing reservoir, was of concrete. The ledge or road which was built for this concrete line in 1918 is being followed by the steel line now under construction.

The contractor for the steel work on this line is the Western Pipe and Steel Company. This organization is supplying 30,000 feet of 26-inch pipe and 7400 feet of 30-inch pipe, on which delivery was begun about the first of last June. The actual installation was begun about ten days later by Brown Brothers, of San Francisco, in a trench previously prepared by the district itself, with its own labor. To date, some 23,000 feet of pipe has been delivered to the trench. All of the pipe is of quarter-inch steel plate, with longitudinal seams electrically welded, and with all-round seams acetylene-welded. J. S. Peters, engineer for the Marin Municipal Water District, has the entire job as a whole under his general direction.

Unusual Difficulties Presented

The installation of the line necessarily presents a difficult problem. The topography of the country, and the character of the bench or road which is being followed, give at once the problem of excessive crookedness and the additional complication of a very narrow base for installation. Almost every one of the 14-foot sections of the line requires a mitre so that its continuity will conform to the line of the trench.

Before welding, the pipe is placed on collapsible wooden trestles set in the trenches. The trestles are all of the same height, about one foot higher than the depth of the trench, making it possible for the welder to stand in the trench and weld over head without necessitating the digging of bell holes.

Sections of the line 500 feet in length are welded in this way by each welding crew. The tie-in welders then weld two of these 500-foot sections together, and the first 500-foot section is lowered into the trench by special lowering devices. The natural spring of 150 feet of line is sufficient to allow for the difference in elevation between the section lowered into the trench and the portion remaining on the trestle.

By welding the pipe on trestles, it is possible to follow accurately the alignment of the winding trench. Despite the sinuous contour of the trench, which in some cases involves sharp angles, it has seldom been found necessary to resort to any digging of the wells of the trench.

Mechanical Obstacles Overcome

Brown Brothers have developed an ingenious device to facilitate the cutting of the ends of the sections in the required angles to secure perfect joints. This contrivance consists of an expanding spider set in the end of the section to be cut. The spider carries at its center a journal into which is set the shaft which carries the end of the cutting torch. The cutting torch is set at a definite angle at the end of this arm so that a beveled cut is made. The arm is adjustable in length so that any variation in the diameter of the pipe can be compensated.

The arm of the cutting torch is set to the required angle by means of a pro-

The bevelling machine, described in the accompanying article, as it appears in operation.

tractor attached to a shaft. The shaft and arm are rotated at any desired speed by means of a worm gear and crank, and thus the ends of the two sections are cut in an absolutely true plane, so that when they are placed together for welding they meet accurately and parallel, and insure a perfect joint. The time required to cut angles is thus materially reduced, and it is possible to make V-welds with a thorough sweat of the welding metal.

Weekly tests are made on shop welding, test specimens being cut from sections of pipe selected at random. At the present writing, thirty pieces have been pulled and only one piece broke in the weld—after developing a weld strength of 94 per cent. All other specimen pieces broke in the metal approximately four inches distant from the weld.

A number of bending tests have been made of the electric-welded joints, and no welds have broken. Four-inch test pieces were bent until the ends met, giving a bend of 180 degrees. From these tests it was concluded by the engineers that it is possible to produce in actual shop practice a one-hundred-per cent efficient electric-welded joint, using quarter-inch plate.

An imported Swedish steel welding rod has been selected, after severe tests of various kinds of rods, for use on this job. The acetylene gas is the product of the Commercial Acetylene Supply Company. The entire line is protected by a spiral wrapping applied after the pipe has been preheated and dipped.

Each User An Owner

The new water system of Earlimart, Tulare County, California, was dedicated on August 10. The Earlimart Mutual Water Company, composed of local business men, first began work on the system on June 10. Each water user is the owner of at least one share, of $100 par value, in the company. The system is composed of a 12-inch well with turbine pump and pressure tank. There are at present 2,093 feet of 4-inch mains.

Shafter Buys Water System

By a vote of 58 to 3, citizens of the Shafter Public Utilities District, Kern County, California, passed a bond issue of $24,000 for the purchase of the present water system and for its further improvement. Lines will be extended into the Lackenmair, Powell, and Potter subdivisions, and the present township will be enlarged. A new pump will be installed.

Seek Transfer of Mendota Company

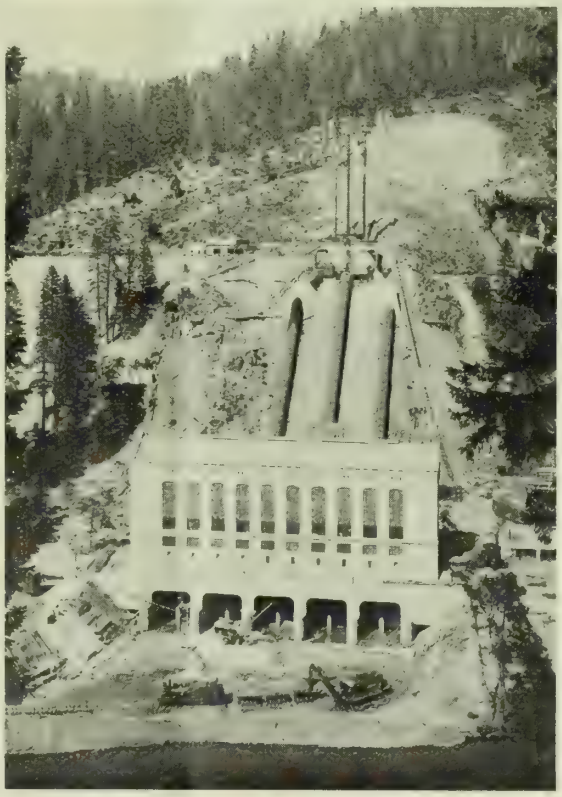
A. J. Arnaudon has applied to the California Railroad Commission for permission to sell, and Mendota Mutual Water Company, to purchase the water system in the town of Mendota, Fresno County.

Two-fold Economy

Permanent protection against corrosion is only one of the important problems economically and effectively solved through the application of

Biturine Enamel

"The Corrosion Preventative"



Pitt River No. 3. Hydro-Electric Power Plant Pacific Gas and Electric Co.

Inside of the ten-foot penstocks coated with Biturine Enamel to prevent both corrosion and tuberculation.

in the Pitt River Power Project. In addition Biturine prevents "tuberculation"—the formation of fungi and other adhesive growths interfering with maximum capacity of pipe lines.

Biturine Enamel has a 20-year record as standard anti-corrosive coating under the severest conditions — including the marine field throughout the world.

Write for our convenient Handbook on "Pipe Protection," authentic information and practical working specifications for corrosion prevention.

NAME.....

ADDRESS.....

FRANK J. KIMBALL CO.

1857 E. 15th St. ***Los Angeles, Cal.***

Says Foes of Big Projects Fail to Grasp Time Element

Secretary Hoover delivered an address at a Los Angeles Chamber of Commerce luncheon early in September on the necessity of developing the country's water resources. The main point stressed throughout was the importance of such development being undertaken on a national scale.

"Water is the greatest undeveloped resource in America today," he declared. "There are 25,000 miles of inland waterways of which less than 6,000 is in use. There are also 30,000,000 acres of land that may be reclaimed by proper water development. The undeveloped resources now going to waste each year amount to billions of dollars."

The opposition to the extensive program he outlined is, Secretary Hoover thinks, largely on the part of agriculture and the railroads. Agriculture fears that the addition of large areas of land will create overproduction, while the railroads fear transportation competition, he said. "If it were possible to bring about this development in a few days, I would be opposed to it myself. But it must be remembered that these projects take time. Even if the program I have outlined could be started tomorrow, it would be at least fifteen years before it could affect agriculture. And it should be remembered also that ours is a growing population. Within the next ten years I believe we will see efforts being made to stimulate agricultural production to provide food for the public. As for the railroads, they have nothing to fear, in my judgment. Demands on transportation are increasing every year at a greater rate than facilities are provided for meeting them."

The Secretary enumerated a long list of controversial points that cause local friction and retard development, and said "These controversies settle nothing. Water development can be settled only by steam shovels and the pouring of cement."

In closing, Secretary Hoover stressed the point that no section should feel that it is interested only in one particular project. "It is necessary to adopt a view that embraces the water development program of the country as a whole. The country should unite in materializing the vision of developing its water resources."

Paving Affects Pipe Line

Los Angeles County Water Works, operating in the vicinity of Gardena and Moneta, Los Angeles County, California, has applied to the Railroad Commission for permission to abandon service from its pipe line located on the west side of Vermont avenue between Southern and Rosecranz avenues in case the county of Los Angeles begins grading Vermont avenue preparatory to paving the same.

Letter Gives Status of Overhead Irrigation in Hawaii

More than the usual interest attaches to the following letter just received by the Editor of this department from K. D. Bond, the agriculturist of the Hawi Mill and Plantation Company in the Hawaiian Islands. A detailed illustrated article describing their installation, the largest in the world, has been promised by Mr. Bond for a forthcoming issue of MODERN IRRIGATION.

"It is with considerable interest," writes Mr. Bond, "that I note the reintroduction of the department of Overhead Irrigation in MODERN IRRIGATION. In the development of overhead irrigation here in the Islands there is indeed a need for the authoritative, unbiased information which you now offer the readers of your paper. It is quite obvious that overhead irrigation would be in a far more satisfactory condition today had those who put in the first installations employed the services of an expert hydraulic engineer experienced in this line. Unfortunately we were not, until recently, aware of the work in California.

"The sugar plantations in the Hawaiian Islands," the letter continues, "are investigating the possibilities of overhead irrigation as applied to cane fields. Already Hawi Mill and Plantation Company has installed 636 acres, though others have been more cautious and as yet have only small, experimental areas. To date there are 764½ acres under this system, representing six plantations.

"The growth of overhead irrigation here has been similar in nature to the growth in California in that individuals here and there have from time to time experimented in a small way with overhead irrigation, often without knowing that anyone else was doing the same thing. The idea has gained ground very slowly and the present attitude seems to be that of watchful waiting for the results of present installations, especially the one here at Hawi.

"It must be acknowledged," the writer states, "that, from the irrigationist's point of view, overhead irrigation on this plantation is far from satisfactory. Those who are watching for harvesting results will unfortunately be given a wrong impression unless we can point out the mistakes in this Hawi system and suggest the remedies. Many of the mistakes are fortunately quite obvious. Others are more obscure and I welcome therefore, the opportunity to put some of these questions before competent authority.

"This is, perhaps, a crucial period in the history of overhead irrigation in Hawaii as many of the other plantations

harvest their experimental areas this year and all will be eager to know the outcome. For the most part the other plantations have adopted the Hawi system, sprinkler head and all. If the harvesting results of these various experimental areas confirm the results at Hawi the cause of overhead irrigation will receive a severe check.

"Fortunately," the letter concludes, "the areas involved are small and the yields are, I believe, better than we have obtained. But in any case it will be necessary to point out remedies and to show plainly where the trouble lies. Not the least thing to be done will be to acquaint the plantations with the types of sprinklers developed in the citrus country."

Cathedral City Gets New System

A certificate has been granted by the California Railroad Commission to Cathedral City Water Company, Riverside County, to operate a public utility water system in the sub-division known as Cathedral City, and to issue $10,000 of common capital stock in payment for the public utility water property. The Commission also established rates for such service based on a minimum of $1.25 per month for 400 cubic feet or less, and ranging from 25 cents per 100 cubic feet for the next 600 cubic feet, and 20 cents per 100 cubic for the next 4,000 cubic feet per month, to 15 cents per 100 cubic feet for all water in excess of 5,000 cubic feet per meter per month.

Will Issue $60,000 Bonds

The North Sacramento Light and Water Company has been authorized by the California Railroad Commission to issue and sell at not less than 95 per cent of face value, plus accrued interest, $60,000 of its first mortgage sinking fund 6½ per cent gold bonds, due July 1, 1946.

The water company will use the proceeds derived from the sale to pay outstanding obligations and indebtedness. The company this spring expended a large sum in improving its water system by the extension of water mains and the installation of a new pumping plant.

Allege Unjust Discrimination

The Inter-City Improvement Association, consisting of consumers of water served by A. B. Chapman Estate, a corporation, in the vicinity of San Gabriel, Los Angeles County, has filed a complaint with the California Railroad Commission against that corporation alleging that the rates and practices of that utility are unjust and discriminatory and ask the commission to fix rates, rules and regulations, affording complainants relief, and to award reparation to complainants if the same are found justified.

Seek Higher Rates

James M. and Florence V. Eva, operating a small water system for domestic purposes in Summer Home Park Tract, Sonoma County, California, have applied to the California Railroad Commission for authority to establish a flat rate of $18.00 per year for domestic service, and to establish meter rates, and for other relief, stating that their revenues are insufficient to maintain the system .

You *Name the* Load
We *Make the* Pipe!

SINCE concrete pipe (as made by Bent) came into its own, engineers question no longer its striking advantages for a great variety of uses. *But*—a concrete pipe installation is either a mediocre or an eminently superior job of work, depending upon who fulfilled the contract.

Many trade names have become hall-marks of tradition, that serve as an unerring guide to discriminating buyers. Today the name "BENT" on a joint of Concrete Pipe marks it as a strictly finely made product. The same care and skill is exercised in its manufacture, and in the laying of the line, as though every future contract depended on *that* job meeting the fullest requirements of specifications—*and more.*

Let us give you a "concrete" demonstration of what we mean by "Bent" Service.

TRADE NOTES *of the* MONTH

A DIESEL BUILT TO ORDER FOR THE EXCAVATOR

AFTER five years of close observation of small Diesel engines, and after considerable study and experimentation, the Northwest Engineering Company has built the Northwest-Cummins engine, a 4-cylinder full Diesel unit that is especially designed for use on excavating and material handling equipment. It is not, the company states, merely a marine engine placed on a shovel, crane or dragline.

The Northwest-Cummins brings the high efficiency of the true Diesel cycle minus the objectionable features of the ordinary true Diesel or the solid injection type.

In the well-known true Diesel cycle, which has been successfully and widely used over more than two decades in large size engines, the fuel is injected into the combustion chamber with a jet of high pressure air. This serves to break up the fuel very finely thus making it more readily and completely combustible. With this method it was naturally very difficult to secure effective operation in small cylinder sizes. First, a high pressure air compressor—an expensive and troublesome affair—was necessary, and second, accurate metering was impossible inasmuch as the metering had to be carried out by a variable stroke plunger pump or equivalent means.

In recognition of the troubles of the air compressor, engineers had been working for years on a solid injection engine that would permit of complete combustion.

Those who devised the Northwest-Cummins method of injection say it is the solution of the fuel metering problem. It brings the effectiveness of the air injection type minus the handicap of the air compressor and is without the high pressure pump and attendant difficulties of the solid injection type.

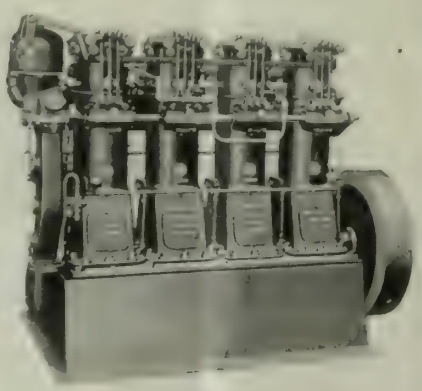
The solution of the metering problem is based on the fact that the fuel pump used on the Northwest-Cummins operates at only 50 pounds pressure. It serves only to keep the fuel at a constant pressure. This permits the use of simple needle valves for fuel metering. The four fuel injectors are fed by a common supply pipe.

A Diesel Dragline Owned by Paris Bros., Berkeley, Calif., and doing work at Rio Vista for the California Packing Co.

Because of more perfect atomization and complete combustion at all loads combined with high compression, the Northwest-Cummins burns a wider range of fuel, thus effecting the maximum in fuel economy. Everything on the engine that ever calls for adjustment or examination is readily accessible and most of those are in separate units easily dismantled or replaced. The cylinders are cast separately. This permits the easy removal of any cylinder.

The Northwest-Cummins is started by compressed air and gives a practically instantaneous start from stone cold. No heating by torch, hot bulb, cartridge or similar device is necessary and there are no electrical devices on the engine.

For starting, a small air compressor driven by a small gasoline engine is provided. This charges a large storage tank. Twenty minutes operation will suffice to fill this tank, and one charge of the tank permits from 10 to 15 starts. Cold or wet weather will not affect the starting of the Northwest-Cummins. It starts under all conditions even easier than a gasoline engine. A fuel tank of 100 gallons capacity is provided. Under the great majority of conditions it is unnecessary to take on fuel oftener than twice a week—a feature worth considering where fuel must be hauled long distances.



This 4-cylinder full Diesel unit was especially designed for use on excavating and material handling equipment.

Death Takes Parsons President

W. C. Bergman, president of the Parsons Company of Newton, Iowa, recently passed away at the age of seventy-one. Mr. Bergman was one of the pioneers in his line. In addition to his interests in the Parsons Company, he was president of the First National Bank of Newton.

Frank J. Kimball Expands

From a little office where engineering service and co-operation with pump users and owners were the keystone of the business, to a modern, two-acre production plant, all in twenty years, is the record of the Frank J. Kimball Company, Los Angeles, California, manufacturers of Kimball direct flow turbine pumps.

For the past ten years the Kimball Company has been located at 1860 East Fifteenth Street, Los Angeles, but the increasing business has compelled their moving to larger quarters. They have sold their present plant to the Liberty Foundry Company, and have bought nearly four acres in the Compton industrial section on East Sixty-second street.

The new plant, which is being erected for them by the Austin company, will cover nearly two acres and will consist of a main building 100x175 feet, a modern pattern shop, and a model garage—the buildings of the latest type factory construction. They will be equipped with the newest and best machine tools and labor saving devices. The entire plant will be devoted exclusively to the manufacture of Kimball direct flow turbine, and the Kimball improved patented air lift pumps.

New Dredge Attracts Notice

The new Clarke dredge began operations for the Imperial Irrigation District (California) the last of August on a contract which will take the dredges over 300 miles of canals. Reports from Imperial say that the new dredge is attracting particular interest because it removes earth from both sides of the canal at the same time, whereas under the system that has been in force the dredges go down the canal on one side only, returning on the other. This means that, if successful, the Clarke dredge can do the work in just one-half the time and consequently one-half the expense. The dredging of silt is one of the greatest problems of the district, but the Boulder Dam and All-American Canal will relieve the valley of this burden, which runs, including the cost to the farmers themselves, to more than $1,000,000 annually.

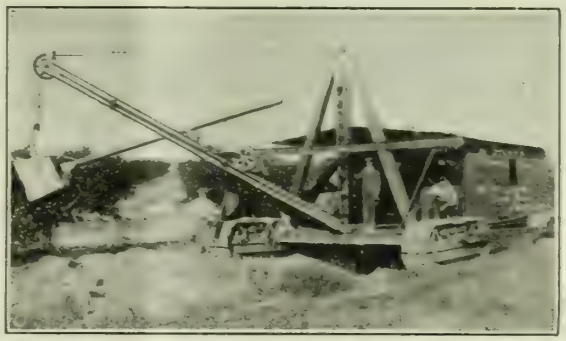
Pipe Line for Famous Ranch

On the famou 20,000 acre Guenoc Rancho near Middletown, California, the property at one time of the celebrated actress Lillian Langtry, the United Concrete Pipe & Construction Company of Merced are constructing a pipe line. They are using a Parson Model 21 ditcher. On this ranch is said to be the largest private dam ever constructed for the impounding of water.

For Cleanout -- Maintenance -- New Ditches

There's a Bay City for Every Job

BAY CITY Land Dredges span the ditch, can dig any desired slope, and dump waste on both banks. BAY CITIES leave clean, wide berms, and can work up or down streams. One trip over the ditch is enough. The Shovel Type Dipper handles hard material in which other types of buckets cannot make a good showing.



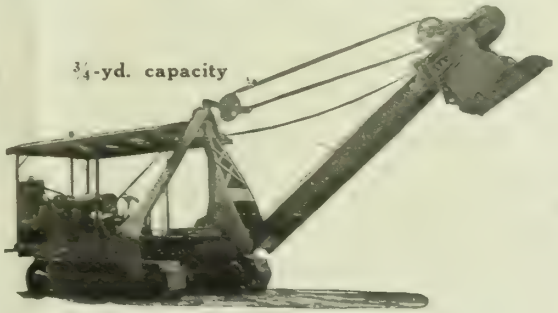
At left—One yard BAY CITY Dredge digging and cleaning ditches in Florida Citrus Groves.

BAY CITY Land Dipper Dredges are built to fit the job. Walking, Crawler, Track or Floating mounting. Easily dismantled, transported and assembled. Capacities ½ to 1½ cubic yards. Oil engine or electric operation.

FOR SMALLER DITCHES — OR PIPE LINE TRENCHES

The BAY CITY 16-B convertible Excavator will handle a wide range of work. Operates Dragline, Trench Shovel, Clamshell or Skimmer. All steel. Shipped assembled. Digs any width or depth up to 20 feet.

STEEL CONSTRUCTION



FULL CRAWLER MOUNTING

or—Model 4 Excavator

BAY CITY Model 4 is a small low-priced convertible, one-man operated Excavator. Fills the gap between hand labor and high priced equipment. Capacity 20 to 40 cubic yards per hour. Gasoline or electric power. A Real Digger economically designed for the small job. Also operates shovel, and clamshell.

RECLAMATION

Hoover Views Reclamation from Tomorrow's Needs--and the Next Day's, and the Next

By HERBERT HOOVER

FOR the past five years the Department of Commerce has, as directed by its organic act, and at the request of the other departments of the government, devoted much of its energies to study of the commercial possibilities in the development of the water resources of our country—inland waterborne transportation, power, irrigation, reclamation and flood control.

The time has come when we must take an enlarged vision of their future. We have arrived at a new era in this development. We have need that we formulate a new and broad national program for the full utilization of our streams, our rivers and our lakes.

Water is today our greatest undeveloped resource. Our streams and rivers offer us a possible total of 55,000,000 horsepower and of this less than 11,000,000 has been developed. Of our 25,000 miles of possible inland waterways probably less than 7000 are really modernized, and the utility of much of these 7000 miles is minimized by their isolation into segments of what should be connected transportation systems.

Vast Area Reclaimed

We still have 30,000,000 acres of possible reclaimable and irrigable lands. And these water resources lie in every part of the union—the great basins of the Columbia, the Colorado, the Sacramento, the San Joaquin, the Mississippi, the Arkansas, the Platte, the Missouri, the Ohio, the Cumberland, the Tennessee, the Hudson, the Great Lakes, the Saint Lawrence, and many others.

True conservation of water is not the prevention of use. Every drop of water that runs to the sea without yielding its full commercial returns to the nation is an economic loss, and that loss in all its economic implications can be computed in billions.

We have for a century and a half concentrated ourselves upon development of our land and our mineral resources; we have conserved our forests and developed our rail and highway transportation. Our government has done some effective work with water, but we have wasted vast sums of public money under political pressures; and we have now skimmed off the easy job. Today it is the major engineering jobs and the opportunity of great national design which lie before us.

The National Outlook

One of the loudest objections that Secretary Hoover hears to his extensive program of utilization of the nation's water resources comes, no doubt, from the agricultural interests, who fear that the bringing under cultivation of additional large areas of land will result in over-production. Hoover's answer to this can best be expressed in his own words:

"I would," he declares, "be opposed to such development myself were it possible to bring it about in a few days. But it must be remembered that these projects take time. Even if the program I have outlined could be started tomorrow it would be at least fifteen years before it would affect agriculture."

Hoover points out that the population of the United States will be increased by 40,000,000 people in the next quarter of a century and that efforts must be made during the next ten years to stimulate agricultural production to provide food for this increase.

The vision of the average agriculturist is hardly able to encompass more than today's and possibly a few of tomorrow's needs. Secretary Hoover looks ahead to the day after tomorrow and to the next day after that. Most of us are so close to our own little problems that we fail to see or even care to see the problems of our neighbor or our neighbor's neighbor. The national outlook is what is needed and Hoover's plan expresses that. "Sectional controversies settle nothing," is the way he puts it. "Water development can be settled only by steam shovels and the pouring of concrete."

—Editor.

Almost unnoticed, the progress of science and engineering has revolutionized the possibilities of our water resources. Inventions in construction methods and tools enable us to economically deepen channels and safely construct great dams.

The discoveries in transmission of electricity now enable distant waterpower to be brought to a market as a vital contribution to the cost of developments for other purposes. We have emerged from the long postponement of national construction imposed by the war and reconstruction; we have recovered so greatly in national wealth that we now have the capital to compass such projects as our expanding needs require and our undeveloped resources make possible.

We must no longer think in terms of single power sites or single storage dams or single land projects, or single navigation improvements; we must think (and thanks to science and engineering we can think) in terms of the co-ordinated long-view development of each river system to its maximum utilization. We have also to face the regrettable fact that these great possibilities of development of water resources are fast drifting into the muck of litigation, political opposition and interstate quarrels, which could be solved by the determination of broad national programs.

I am not proposing that all these things should be done tomorrow. At this moment we could not make economic use of the whole of this power or all this land, or all these inland waterways—but we will need the whole of it within half a generation. And at this moment we have the urgent need for beginning certain major projects which will require years for completion.

*Excerpts from an address delivered on August 21 before the Columbia River Basin League.

Today we are expending on isolated works under the rivers and harbors appropriations and under the reclamation act sums aggregating perhaps at most 65 millions a year. It is my own view that the federal government can well afford to enlarge its financial program in contribution to the great permanent structures; to pour the cement and dig the channels for this great development and to organize such collateral support from the states and collect such returns in by-products as sound procedure and good sense will offer.

An increase by the federal government beginning at $25,000,000 and rising to $100,000,000 a year together with the collateral expenditure of states, local communities and the hydro-electric companies would complete many of our most pressing projects in the next ten years. Much of this expenditure would be directly recovered from land and from leases of by-product power. It is all of it a capital outlay not a disappearing expense.

Realization of these plans will bring economic well-being measurable not in millions but in billions. We could for the immediate projects that lie before us even find a return in money by the increment in federal income tax alone, for the growth of national income and wealth would finance and more than warrant any such national outlay. We are all engaged in the great effort at tax reduction, but a soundly run business house not only looks to its expenditures but it looks for increased revenues. A nation can reduce its tax-rate by increasing its wealth and thus causing a spreading of the burden. These are reproductive works we are talking about. They are not charity to any locality.

We have fortunately grown out of the period of the pork barrel in river and harbor improvements. The distinguished action of Congress by which the broad distribution of appropriations is left to the United States engineers removes from all these proposals the charge of political waste. To have definite policies and plans for each drainage will be a further assurance of efficient expenditure.

Imperial's Drainage Problems

(*Continued from Page 16*)

feet is now under construction. The first tile placed was an experiment to determine if water could be collected from the tighter soils. The results were quite satisfactory, and it is expected that many miles of the tile will be placed before all the small local areas have protection.

The section used for the open drains varies from 6-foot base, with 1:1 side slopes, to 12-foot base with 1: 1½ side

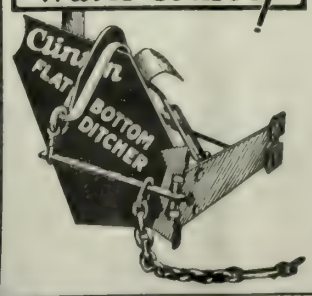
Make Your Ditch a Natural Water Course



Here are—
5 Advantages:
you'll appreciate in this tool:

1. It builds a ditch which carries more water than a "V" ditch, depth and fall being equal.
2. The "off" horse walks on the flat ditch bottom instead of on the slope.
3. Silt fills this type of ditch more slowly and there is less overflow.
4. Erosion is minimized in the flat bottom ditch.
5. It can be cleaned out with greater ease for it keeps its shape.

Los Angeles, Cal.

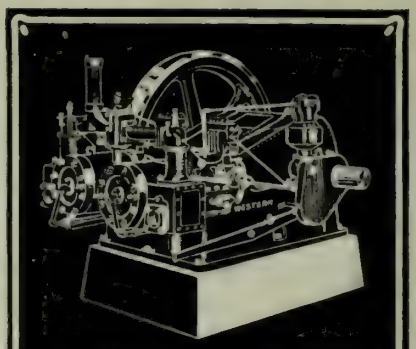
slopes. Depths of cut run from 10 feet to 14 feet; 11 feet being the average sought for with instructions to the machine operators to work one foot below grade. In one case cuts as much as 25 feet were encountered, this being the only way out of the saucer-shaped area known as the Mesquite Lake District.

Modern Structures, Methods

The structures for the drainage system have been somewhat varied, both as to style and materials. Timber bridges of the 3 span type have generally been used for the highway crossings. Ingot iron flumes of the Lennon type are used in the main distributing system wherever possible. In cases where combination structures could be used to pass one or more canals and a highway over a drain, Armco corrugated pipe was specified and placed in the drain. These installations were always made 2 feet below grade to allow for future cleaning and deepening. Armco corrugated pipe has been used instead of flumes for irrigation canal crossings where it was desired to keep the bottom grade of the canal down for sluicing and still be able when required to make a high delivery of irrigation water at the outlet end. This was accomplished by using a high concrete headwall on either end of the pipe.

For the removal of the material in the open sections, draglines were used exclusively and have proved very satisfactory. At one stage of the construction 14 machines were in operation on various drains at one time. On very wet work the machines moved on mats constructed of heavy timbers (generally 8-inch by 8-inch) held together by cables. Mats have been necessary on not over 15 per cent of the work. It has been the rule that where mats were required trouble would be encountered in getting to grade due to the sloughing of the banks. This was overcome by making several light cuts which allowed the banks to drain out a little at each trip over. In no case was the machine operator allowed to stand and fight the material. He was required to take more cuts if necessary. As many as five cuts have been made over a single portion of the drain, but good side slopes with proper grades were finally obtained.

For the tile drain the regulation trencher was used. This equipment operated satisfactorily with one exception. The exception occurred when a very thoroughly saturated adobe dike was encountered and the material would not clean off the buckets. In this case, a dragline being at hand, it was moved onto the job and the section opened up with 1:1 side slopes. When the adobe dike had been passed (some 300 feet) the trencher was returned to the work.



"WESTERN" GAS ENGINES

It has been necessary to shore rather heavily on the greater portion of the tile work to prevent the sides from caving in on the workmen. The average cut on the tile drain has been 10 feet.

Continuous Progress

The first drainage work was started in 1922 and has been in progress continuously since that time. A total of 175 miles of drains, involving the excavation of nearly 9,300,000 cubic yards of material, have now been constructed. The average cost per yard, including a plant charge, is $.087. At the present time an additional 25 miles of open drains are contemplated. This will not completely drain the irrigated portion of the valley, which is about 500,000 acres, but will exhaust the funds now available. It is estimated that at least 100 additional miles of drains will be required to come near completing the drainage system. This is believed to be the largest drainage problem of any irrigation project.

With this great mileage of open drains constructed and contemplated, the district is faced with a real maintenance problem. So far as is known, very little machinery has been designed especially for the care of deep drains. The condition has been met rather satisfactorily by using light, fast machines equipped with ½-yard clam shell buckets. The true center line of the drain is staked by high splines, and the vegetation, such as tules and small willows, is cleaned from the side slope on the machine side and to a point three feet past the center line toward the opposite bank. The remaining vegetation is not removed as it is considered an asset to the maintenance. The clam shell then digs a very narrow trench on the center line of the drain. The roots of the vegetation hold the material from slipping into the trench, and the vegetation on the bank tends to shade the channel. The water course being narrow, the velocity is therefore speeded up which further restricts the growth of the vegetation. This method is quite expensive, costing about $450.00 per mile, one machine being able to cover from 4 to 4½ miles per month. However, one thorough cleaning is good for two years and it is believed that with lighter and cheaper machines than the ones used, which were on hand, the cost can be materially reduced.

The construction work has been handled entirely by force account methods. D. W. Murphy, consulting engineer, of Los Angeles, prepared the original plans. M. J. Dowd, as general superintendent of the Imperial Irrigation District, is the executive head, and the writer is directly in charge of field engineering and construction work.

PIPE

Both USED and NEW--At a SAVING to YOU!

WHENEVER and wherever you need pipe of any size or dimension, Pacific can serve you and save you money, too. For general farm and irrigation purposes, Pacific Reconditioned Casing is a real bargain. Absolutely guaranteed. Every length straight and clean with new threads and couplings, each protected from damage in shipping by special steel protectors.

Every length rattle-tested and steam pressure-tested as proof against weakness; then dipped in a special non-tasting hot asphaltum which resists alkali and corrosion. This adds years to its life. Nowhere else in the West, except in the Pacific plant, can used pipe be so thoroughly reconditioned and then sold at such low prices.

WHO'S *WHO* AND WHO'S *WHERE*

IN THE WORLD OF HYDRAULICS

Personal Notes and Impersonal Observations About Men You Know

C. H. Howell, engineer in the Denver office of the Bureau of Reclamation, has resigned to accept a position with the middle Rio Grande conservancy district.

William S. LaLonde, Jr., of the city engineer's office of Los Angeles, has recently been appointed instructor in civil engineering at the University of Nebraska.

Walker R. Young, who made the survey for the Boulder canyon dam in the Colorado river, is construction engineer in charge of the work being carried on in the Kittitas division of the Yakima project, Washington.

W. F. Bemister has been appointed by the Canadian National Railways as supervisor of fire protection for the western region, with headquarters at Winnipeg, Manitoba. He succeeds W. J. F. Craig, deceased.

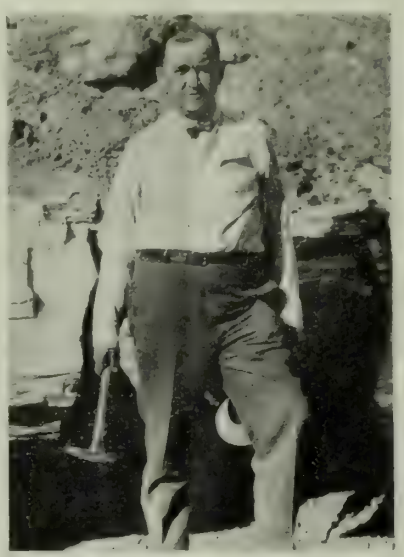
J. J. Hubbell, who has been with the Gila River irrigation project in Arizona, has been transferred to Washington, where he will take charge of the Lummi reservation project under which 4000 acres of tide lands are to be reclaimed.

J. L. Lytel, superintendent of the Yakima project, Washington, reports that the project is closing an unusually successful irrigation season, although the extremely dry winter of 1925-1926 has made it necessary to handle the water with the greatest care.

Ora McDermith, for the past five years consulting engineer of the Kittitas reclamation district, with headquarters at Ellensburg and Seattle, Washington, has been appointed consulting engineer for the entire reclamation service. His first assignment in his new position will be on the Carlsbad project in New Mexico.

Walter L. Drager, has resigned his position as construction engineer with the U. S. Bureau of Reclamation, Denver, and has been appointed construction engineer with the J. G. White Engineering Corporation on the Santiago Dam at Aguas Calientes, Mexico. The Santiago project, one of the divisions of Mexico's irrigation program, will cost according to estimates, $4,000,000.

Porter J. Preston, manager of the Yuma project, is one of a commission appointed by the U. S. Reclamation service to investigate the cost of operating reclamation or irrigation projects, both public and private. During their itinerary the commission will visit more than forty irrigation projects in the west. Later in the fall they will visit Yuma and check over the cost of operating the Yuma project.



A GOVERNOR IN ACTION

The photograph shows James Graves Scrugham, chief executive of the State of Nevada, on a recent trip of investigation of certain of the state's mineral resources. Governor Scrugham has written for Modern Irrigation an article on "What Irrigation Has Done for My State—Nevada," which appears in this issue.

Frank C. Emerson, state engineer for Wyoming, is the Republican nominee for governor. Mr. Emerson was appointed state engineer in 1919, and in 1921 was reappointed by Governor Carey for six years. He was removed by the late Governor Ross for alleged misconduct in connection with the confirmation of his appointment by the Senate. Mr. Emerson contested this removal and was reinstated by the state supreme court in January, 1924.

Joseph L. Burkholder, who drew the plans for the Elephant Butte project in New Mexico, was chief honor guest at a banquet given the officials of the Elephant Butte Irrigation district during a recent conference held there.

Secretary Hubert Work addressed the Western States Convention at Denver, Colorado, on the subject of "Public Lands." He stated that he believed a revision of the public land laws was necessary—that many of the statutes now being administered were enacted to meet pioneering conditions. He is in favor of a repeal of the stockraising homestead act and of the desert land act, and thinks that a law authorizing the establishment of grazing districts should be enacted.

W. M. Reed, chief engineer of the United States irrigation service, on his recent annual trip of inspection, is quoted as saying that the Yakima Indian Reservation Irrigation project is the most prosperous of the ninety-odd projects the service is operating today. That project is not only the largest at the present time, Mr. Reed says, but is the most productive. The bureau keeps an accurate check of the amount and nature of the crops raised on each of its projects, so that there is no guess work about it.

The South African Government is taking a wide-awake interest in matters of irrigation. H. R. Roberts, of the irrigation department of the Union of South Africa, and D. G. Collett, chairman of the Irrigation Board of Graaf Reinet, South Africa, have been inspecting various projects in the west, while word comes from the Denver office of the Bureau of Reclamation of a recent visit from S. B. Shannon and N. Shand, engineers from the irrigation department of the South African Government who are visiting in this country for about a year and are making a study of American irrigation projects.

Water Shortage Damages Crops

Among the irrigation projects of the Bureau of Reclamation crop damage from shortage of water is certain on the Okanogan project in Washington, according to a statement issued in August by the Department of the Interior.

Minor crop damage can be averted only by unusual summer rains on the Yakima project in Washington, the Boise and Minidoka projects in Idaho, and the Milk River and Sun River projects in Montana by reason of depletion of storage on which these projects are largely dependent in late summer. On the Yakima project much water has been lost through illegal diversion of project water by other interests. A threatened severe shortage on the Truckee Division of the Newlands project, Nevada, has been materially reduced by initial steps in administration of Truckee River waters in accordance with a pending adjudication decree.

Unusual rains in early summer, combined with newly completed pumping installations, have removed all danger of shortage on the Salt River project in Arizona.

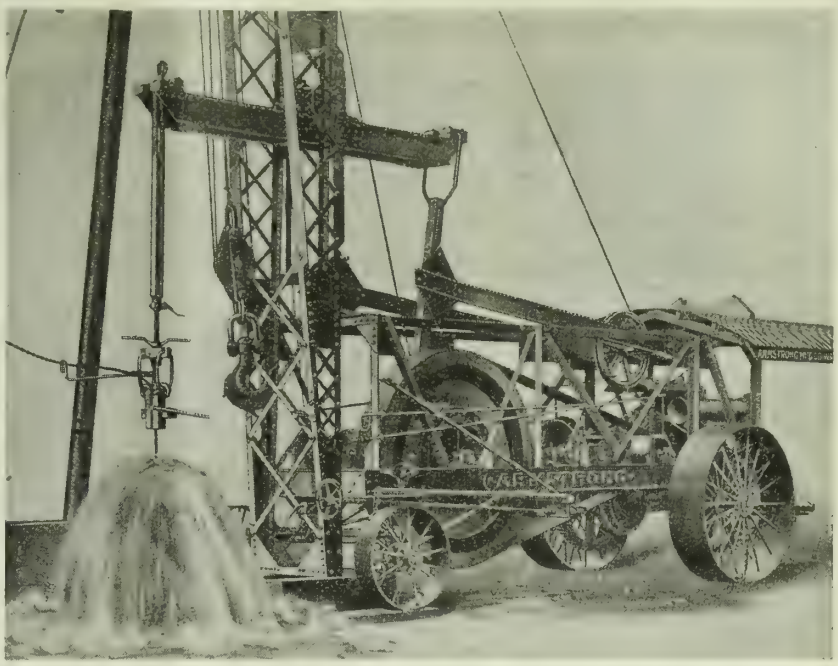
Classify Western Lands

Classification of 20,000 acres of public land in the State of Oregon as valuable for water-power purposes was made public in August by the Interior Department in connection with the land classification report of the Conservation Branch of the Geological Survey for the month of July, 1926.

The report shows that nearly 9,000 acres of public land in Arizona and Nevada were included in formal orders designating the land as nonirrigable under the enlarged-homestead act and to that extent subject to entry as homesteads of 320 acres or less. More than 100,000 acres in Idaho, Montana, Nevada, New Mexico, Washington, and Wyoming were classified under the stock-raising homestead law and designated for entry in tracts of 640 acres or less. Much of the acreage involved in these designations is included in original entries or in applications under the enlarged and stock-raising homestead acts which confer a preference right.

Seeks to Cancel Contract

The Medford Irrigation district (Oregon) has applied to Rhea Luper, state engineer, for approval of a resolution adopted by the district for cancellation of a contract with the Rogue River Canal Company for the construction of an irrigation district. It is charged by the petitioners that the canal company has failed to comply with the provisions of the contract.



The Armstrong All-Steel Drill

"Built for Service Since 1867"

THE frame and derrick of the ARMSTRONG DRILL are all steel. The main sills of the frame are steel channel. The upper part is made of steel angle bars, with braces and trusses all hot riveted in place. There are no nuts, screws, nor bolts to get loose or drop out. There is nothing about it to rot, rust, check, crack, break or wear out. It is as rigid as the skeleton of a sky scraper—as strong as a steel bridge—built to last an age. It cannot warp, spring nor twist out of shape, and always holds the shafting and bearing in perfect alignment. It has been designed and built for maximum strength and long life.

LEGAL *and* JUDICIAL

A DEPARTMENT CONDUCTED BY HANKINS & HANKINS

Irrigation District Is Public Corporation

Wyoming irrigation district law upheld by Supreme Court.

In defining the status of an irrigation district under the laws of Wyoming the Supreme Court in the case of Sullivan vs. Blakesley, et al., 246 Pac. 918 (June 15, 1926) states:

"An irrigation district, reclaiming, as it does, desert lands of the state, and accordingly conferring a benefit, not alone upon the private individuals within the district, but also upon the people of the state as a whole, is a public, rather than a private, corporation." . . . . "Such districts have at times been designated as municipal corporations, and they might be such within the meaning of laws or constitutional provisions not now under consideration, but it is clear that they are not municipal corporations as generally understood. They are merely special state organizations for state purposes with limited powers, created to perform certain work which the policy of the state requires or permits to be done, and to which the state has given a certain degree of discretion in reclaiming desert lands."

This case also brings up the old controversy as to whether or not bonds issued by an irrigation district constitute a general lien obligation of the district, citing cases holding both ways. The court states:

"The difference in opinion as to the character of such bonds may, to some extent at least, be accounted for by the difference in the laws of the several states. . . . ."

Evidence Must Show Intentional Abandonment

Failure to keep system in repair though strong evidence is not conclusive. Strong evidence is necessary to show abandonment of reservoir.

In the case of Munson v. Schade, 247 Pac. Rep. 454 (Colo. June 7th, 1926) a question was raised as to the sufficiency of the evidence to sustain a finding of the court against a question of the abandonment of a reservoir.

The evidence was to the effect that the irrigation scheme in controversy was originally impracticable; that the reservoir and dam had only been used to a very limited extent, was out of repair and had been more or less abandoned. The ditch system, however, had been used, although not under the original scheme of irrigation.

The Supreme Court of Colorado held:

"The reservoir was a part of their general plan; the use of the water was another part; and, while it requires strong evidence to show the abandonment of a valuable right, not less if not more does it require to show an abandonment of a valuable part of a system while the remainder is maintained."

Various excuses were offered at the trial of the case for a failure to keep the system in repair, such as the poverty of the owner of the system, the desire for sub-irrigation, etc.

In reply to these points the court states:

"The real question is, What did these several consecutive owners intend? The court has found in favor of the defendants on that point, (No intentional abandonment) and, though their long delay in repairs is strong evidence against them, yet we cannot say that it is conclusive."

Court O. K.'s Bean Growers' Expenditures

The use of money to properly influence legislation is not against public policy.

A decision which is of interest to those who are following the fortunes of the case of Crawford vs. Imperial Irrigation District now pending before the Supreme Court, was rendered by the Supreme Court of the State of California on August 2, 1926, in the case of California Bean Growers' Association vs. Rindge Land & Navigation Company, 72 Cal. Dec. 149.

In this case the Association had expended certain moneys in an effort, by having representatives appear before Congress and its committees, to have the tariff rates on beans increased. The defendant claimed this was an unlawful expenditure of the Association's money. The court states:

"No attempt was made to show the particular purpose for which the money was used or for what it was illegally or improperly expended. It is neither illegal nor improper to expend such reasonable sums as may appear to be necessary to present, by fair and open means, the merits of any matter advocated before a legislative body (6 Cal. Jur. 126). It is to be presumed, in the absence of evidence to the contrary that such means were employed."

In the Crawford case the Imperial Irrigation District had employed an agent to appear before Congress and its committees concerning the Boulder Canyon Project. The trial court held that any payment to this agent was unlawful.

"Arid Region Doctrine" Versus State Laws

Under laws of New Mexico all water questions are controlled by statutes.

In the case of Harkey v. Smith, 247 Pac. Rep. 550 (New Mexico, Apr. 17, 1926), the Supreme Court of New Mexico reviews the law concerning water rights as affected by the Statutes of that State, stating:

"It may be stated generally that, under the arid region doctrine, uncontrolled by statute, the appropriation of water is accomplished by the taking or diversion of it from a natural stream or other sources of water supply, with intent to apply it to some beneficial use or purpose, and consummated within a reasonable time by the actual application of the water to the use designed, or some other useful purpose. . . . . Under this doctrine it is quite as necessary to make use of the water as it is to divert it, in fact, no appropriation can be effected without such use. The intent, diversion and use must coincide.

"As a result of this doctrine, there flows naturally and necessarily the further doctrine of periodical or seasonable appropriation. If a farmer makes use of the water for the irrigation of his crops only during the growing season, say from March 15th, to October 15th of each year, the same may be appropriated by a mill owner for power purposes, by a placer miner for the washing of his gravel, or by another farmer for irrigation purposes, or by another for storage for future use, during the remainder of the year. This is the established doctrine everywhere, in the absence of statutory regulations.

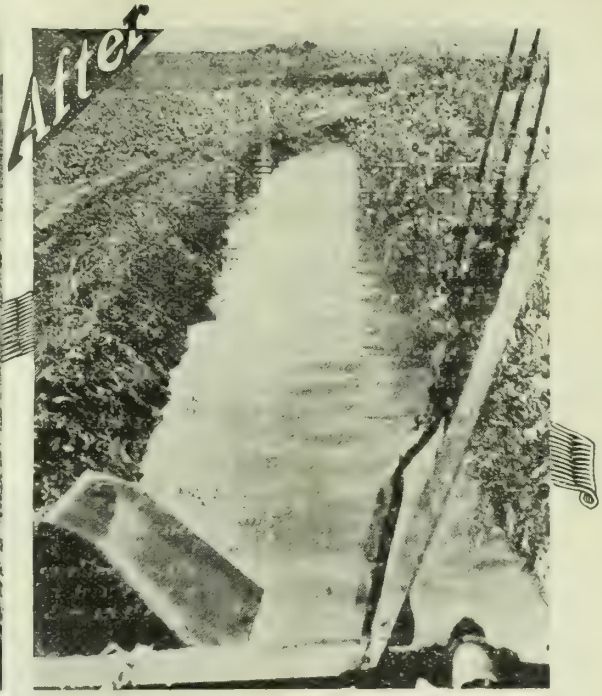
"We have, however, a statute in this state, (New Mexico) regulating the acquisition, means, and manner of enjoyment of water rights which controls the whole matter, and which marks a wide departure from the doctrine above stated."

In applying the statutory provisions of the water act of that state the court further held:

"A careful re-examination of this legislation convinces us that there has been a departure from the old arid region doctrine of appropriation and seasonal or periodical appropriation, and that now the right to the use of water, either as to volume or periods of use, is regulated either by the permit of the State Engineer, or the decrees of the courts. It is, of course, true "that beneficial use shall be the basis, the measure, and the limit of the right to the use of water," as is provided by the constitution. But this provision merely declares the basis of the right to the use of water, and in no manner prohibits the regulation of the enjoyment of the right."

(*Continued on Page 53*)

Digging, Cleaning Canals - *at Low Cost*



THE NEW RUTH DREDGER digs successfully in either dry or swampy ground. With its quick adjustable elevator, operating from either side of the dredger and its high speed endless chain of automatic self-emptying buckets and consequent uninterrupted flow of dirt, and ease of mobility, it operates at a minimum cost per cubic yard or lineal foot, heretofore considered impossible.

The RUTH cuts smooth even banks and bottoms—cleans canals, whether empty or filled with water, of all muck, sand, tulles, small willows and water grasses.

Write describing the type of work you contemplate doing and our engineers will gladly co-operate with you in selecting the dredger best adapted to your needs.

Send today for BULLETIN No. 9—it illustrates the NEW RUTH DREDGER, type and size of canals it digs or cleans, and gives specifications, maximum capacities, and operating costs.

IRRIGATION ENGINEERING

By ARTHUR POWELL DAVIS, D. SC.

Chief Engineer and General Manager, East Bay Municipal Utilities District; formerly President Am. Soc. C. E.; formerly Director and Chief Engineer, U. S. Reclamation Service.

AND

HERBERT M. WILSON, C. E.,

Mem. Am. Soc. C. E.; former Chief Engineer and Irrigation Engineer, U. S. Geological Survey.

Seventh Edition, Revised and Enlarged; Total Issue 12,000

THIS IS a rewritten and rearranged edition with much new material added. The principal difference introduced is the treatment of soils, plant food, operation and maintenance, and other lines of work where the duties of the irrigation engineer come in contact with the irrigator, such as in the preparation of land, the duty of water and its application to the land. A bibliography of standard works is given at the end of each chapter. 640 pages. 6 by 9. 249 figures and illustrations. Cloth, $4.50 net postpaid. Remittance must accompany the order. Allow from one to two weeks for transmittal of order and shipment from the publishers.

IRRIGATION PRACTICE *and* ENGINEERING

By B. A. ETCHEVERRY,

Professor of Irrigation Engineering, University of California.

In three volumes—the most comprehensive work in the field. A wealth of information of both practical and informative value for everyone interested in water development and conservation. Prices are net postpaid and remittances must accompany order. Allow from one to two weeks for transmittal of order and shipment from the publishers.

Vol. 1.—Uses of Irrigation Water and Irrigation Practice.....$2.50
Vol. 2.—Conveyance of Water..... 4.00
Vol. 3.—Irrigation Structures and Distribution System..... 4.50

OVERHEAD IRRIGATION

CONDUCTED BY WM. J. B. STEWART

"OVERHEAD" HAS CAST ASIDE ITS SWADDLING CLOTHES

By FINGAL C. ORR, M. E.*

OVERHEAD irrigation may now be considered as having come to stay. It has passed through the experimental stage and has proved its advantages as to conservation of water, saving of labor, reduction of upkeep on tools, etc. Through the three years just past it has emerged from what was regarded as a doubtful experiment into a practical success.

The honor due for the results obtained lies with those pioneer growers who devoted their time and money to the earlier trials, and who, having the courage of their convictions, were not afraid to take a chance.

The earliest grove in which overhead irrigation was installed, so far as the writer has been able to learn, was located at Covina, California. The system there was installed about fourteen years ago. Then followed several installations of a portable nature in Sierra Madre and vicinity, and at least one located at La Canada and another at Glendale. What might be considered the first practical installations of a strictly modern type were located at San Gabriel, California, on the Sunny Slope Water Company's lines.

On a Stable Basis

The commercial end of the overhead irrigation enterprise may also now be considered as fairly well on its way towards satisfactory organized endeavor. Of course during the early days, while the business was still in the "growing pain" stage, as it were, there were the usual crop of "fly by night" outfits who broke into it, ready enough to start something but lacking the stability to finish, who made some very regrettable installations, thrown in without due regard to the engineering requirements of the case in hand. Fortunately for the development of the business, these cases were not numerous and the harm done was more than offset by the satisfactory work of the men who were qualified.

During this period it was naturally hard for the grower to know who was, or was not, competent to undertake this work. Many people have asked the writer whether it was necessary to employ the services of a fully qualified engineer to make the necessary pipe layout

FINGAL C. ORR

on paper for a proposed installation. It is the writer's belief that it is, of course, well to be sure that the man doing this knows his business. There are quite a few men, who do not claim full qualifications as engineers, but who have made an intensive study of this particular and practically new branch of hydraulic engineering, and they are making thoroughly satisfactory installations. These men might be termed overhead irrigation specialists. For the most part they are men who have had years of experience in the pump business and were, therefore, prepared to take up the new business when the need arose. Should one have any doubt, however, as to the correctness of a proposal, it is only a matter of having it checked over for possible mistakes by any hydraulic engineer experienced in this line of work.

Approves Reconditioned Pipe

The question has been raised from time to time as to the advisability of using reconditioned pipe for this purpose. The experience of the writer would tend to show that, as long as the pipe is free from pits, blisters, and other blemishes, and is treated with a coat of petrolastic cement both inside and out, there is no reason why it should not last the life of any grove. It must be borne in mind, however, that in securing this grade of material one must be careful to obtain same from a reliable firm which makes a practice of thoroughly cleaning the pipe, both inside and out, before dipping it in the hot solution. In order to obtain the best results, it is necessary for the metal to be left in the hot liquid until both are of the same temperature.

The lasting qualities of a pipe are in proportion to its thickness of wall, the larger pipes being usually much heavier in the wall than those of smaller diameter. It has been my experience that the fewer pipes laid of small diameter the better. I have, therefore, always advocated strongly the large coverage sprinkler, the modern types of which give a thoroughly satisfactory distribution of water.

The question of how much water to lay down in a given number of hours is a matter controlled by many factors, such as soil porosity, the actual number of gallons per minute of water available, and the extent of the acreage to be covered. Where the volume of water is not restricted, it is a matter best decided by the grower himself. It depends upon how heavy an irrigation he wishes to apply and the number of hours he desires to do it in. This information in the hands of one competent to use the necessary figures will enable him to determine the size of pipes, etc., necessary to handle the situation with the greatest efficiency.

*Mr. Orr is one of the pioneer engineers who conceived the idea of putting overhead irrigation on a sound engineering basis. He is the inventor of a number of devices now on the market which first made possible economic, wide coverage.

OVERHEARD AMONG THE *OVERHEADS*

Various overhead irrigation installation contractors, operating from Los Angeles headquarters, report many new jobs recently contracted. The prospects are for by far the largest fall and winter installation boom on record, they believe.

The numerous requests from far and near for information on overhead irrigation systems that are being received by the Thompson Manufacturing Company attest to the wide and rapidly growing interest in this most modern means of irrigation. The sizes of the installations contemplated vary from one to six hundred acres.

For the efficient operation on low pressure the seven-and-one-quarter-acre system on the ranch of E. D. Ingalls in north-east San Diego county is asserted to set a new record. The Rainlyk sprinklers are set to cover five trees net to each sprinkler and the coverage with a rain like shower with only fifteen pounds pressure is said to be very even. The system was designed by Lippincott and Stewart.

The avocado growers' field day tour, conducted in connection with the Los Angeles County (Calif.) Farm Advisor's office, to view avocado groves irrigated with sub-irrigation, basin and furrow methods, and with overhead systems, was one of the most interesting ever fostered by these two active organizations. It was held on Wednesday, Sept. 15. Details of the tour will be discussed in the October number.

A new sprinkling system, remarkable for its completeness has just been installed on the athletic field of the El Monte, Cal., High School by the Hadden Automatic Sprinkler Company. The two-acre plot of light, dusty soil has been forced, through frequent applications of the proper amounts of water, automatically controlled, and by means of liquid fertilizer applied through the system, to grow a turf in a little over six weeks' time that is expected to stand the fall football practice at that institution.

An old landmark in the overhead irrigation field has just passed with the taking over by the Western Pipe and Machinery Co. of the pipe yard and business in Los Angeles of Samuel H. Gerson. A. Lutz is the new proprietor.

Several of the present overhead irrigation contractors were connected with the Gerson yard at one time or another during the early stages of development of the overhead business. Gerson was the first of the pipe yard owners to become interested in using re-conditioned pipe in overhead systems, having first secured favorable results from such a system on a lemon grove of his own at Sierra Madre.

"Trouble shooting" on overheard irrigation installations is, to say the least, a new business and as it is one that has few precedents to go it frequently tests the ingenuity of those whose services are called upon. Although some of the cases are so serious as to necessitate "major operations"—that is, extensive remodeling of the systems—it is frequently found that a simple auxiliary device or a change in schedule of nozzle will remedy a situation seemingly hopeless to the grower.

A system in Orange county had from the first given trouble from asphalt, pipe scale and canal detritus stopping up the screen boxes, riser screens and small sprinkler openings. The work attendant on operating such a system grew more irksome than in irrigating with the old furrow method, and the grower after getting little satisfaction in endeavoring to eliminate the various points of trouble was on the verge of returning to the old method.

When a "trouble shooter" from Lippincott and Stewart was called in two of the mains and several of the laterals were found to be from one-half to two-thirds full of material that would have passed through the major nozzle if proper sized riser screening, with a properly maintained pressure had been employed. Flushouts were installed, proper meshed riser screens and special screen devices to protect the minor nozzles from plugging were provided and the system, fundamentally o. k., is now functioning to the grower's satisfaction.

Refusal to Supply Water Upheld

The California Railroad Commission has dismissed the complaint of A. O. and Martha L. Barnes against East Gardena Water Company, in which the Railroad Commission was asked to require defendant utility to extend its mains to complainant's property. It was shown at the hearing of the complaint that the facilities of defendant utility were taxed to the limit to supply present consumers.

For Detailed Listings, Branch Offices, Etc., See the Buyers' Guide to Leading Supply Sources—Pages 55-56

WHAT IS *YOUR* PROBLEM

In this department, questions of general interest to overhead irrigators will be answered for our readers. Should special or earlier answers be desired, a stamped addressed envelope should accompany each inquiry. There is no charge for this service.

How much can I save by installing an overhead system myself on six and three-fourths acres? G. L. P., Tulare County, Calif.

It is doubtful whether you could save anything by doing the work yourself, even at your distance from the center out of which most of the overhead irrigation contractors operate. The experience that contractors have acquired in doing many jobs would, generally speaking, assure certain economies and expeditious workmanship, the benefits from which would accrue to you under a fair agreement with a contractor willing to operate at that distance away from his base.

We have in mind one careful grower who was going to learn all about overhead irrigation installations, sprinklers, layout, etc., in a few weeks; then buy the best equipment, install it himself and set a new mark for operating efficiency. He based his confidence on his practical experience in other construction lines. His overhead system, however, has cost over five hundred dollars per acre, is badly sand trapped, and he is still looking around for sprinklers to throw odd shapes to avoid excessive overlaps in places and to cover the spread on the low pressure sections, etc.

Can you tell me if overhead irrigation is practical and economical in growing alfalfa on level sandy loam soil? E. T., Los Angeles County, Calif.

The opinion of the University of California experts delegated to study and report on overhead irrigation was to the effect that overhead irrigation is costly, this factor limiting its use to valuable crops.

The investment per acre would be considerable for land on which to crop alfalfa permanently, or for ten years, let us say, and it is a question whether the increased production would carry the investment interest charge and depreciation and show a profit in competition with cheap land and water producing the same.

If you planned to build up the soil humus preparatory to planting to other more valuable crops or trees which would thrive under overhead irrigation, the installation at this time would, of course, be advised.

SURVEY *of* HYDRAULIC DEVELOPMENT

As Shown by Official Records of the Month -- Local, State, and Governmental

Applications Filed

Among the applications for permit to appropriate water filed with the State Department of Public Works Division of Water Rights (California), during the month of August, 1926, were the following:

Application No. 5140 (Riverside County)—Henry M. Jones, care of Oliver P. Ensley, Hemet, Calif., for 1 cubic foot per second from Poppet Creek tributary to San Jacinto River. To be diverted in Section 21, T 4 S, R 1 E, S. B. M. for power purposes in Section 21, T 4 S, R 1 E, S. B. M. 14 T. H. P. to be developed. Estimated cost $1,500.

Application No. 5141 (Shasta County)—James A. Hubbard and W. C. Blagrave, care of W. D. Tillotson, N. Calif. Nat'l. Bank Bldg., Redding, for 125 cubic feet per second and 9600 acre feet per annum from Clear Creek tributary to Sacramento River. To be diverted in Section 22, T 32 N, R 6 W, M. D. M. for irrigation and domestic purposes on 19,200 acres in T 31 N, Rgs. 5 and 6 W, M. D. M. Estimated cost $380,000.

Application No. 5143 (Butte County)—State Land Settlement Board, care of C. M. Wooster, 915 Mission St., San Francisco, Calif., for 20 cubic feet per second from Butte Creek tributary to Sacramento River. To be diverted in Section 5, T 21 N, R 2 E, M. D. M. for irrigation purposes on 3450 acres on Durham State settlement.

Application No. 5144 (Sierra County)—G. R. Holcomb Estate Co., R. F. D. No. 1, Reno, Nevada for 28,000 acre feet per annum from Little Truckee River tributary to Truckee River. To be diverted in Section 16, T 19 N, R 15 E, M. D. M. for irrigation purposes on 6,000 acres in T 18 and 19 N, Rgs. 19 and 20 E, M. D. M. Estimated cost $150,000.

Application No. 5145 (Butte County)—Maude C. Maddrill, care of Jerome D. Peters, Bank of Italy Bldg., Chico, Calif., for 15 cubic feet per second and 4,000 acre feet per annum from Clear Creek via Butte Creek tributary to Sacramento River. To be diverted in Section 4, T 21 N, R 2 E, M. D. M. for irrigation purposes on 1042 acres in Sections 7, 8, 9, 17 and 18, T 21 N, R 1 E, M. D. M.

Application No. 5147 (Inyo County)—Pacific Lead Mines Incorporated, 1111 Stock Exchange Bldg., Los Angeles, Calif., for 0.25 cubic foot per second from Unnamed Spring tributary to Death Valley. To be diverted in Section 28 or 34, T 12 S, R 45 E, M. D. M. for mining and domestic purposes. Estimated cost $2,000.

Application No. 5148 (Santa Cruz County)—Felton Water Company, Felton, Calif., for 0.26 cubic foot per second from Limestone Brook and Scott Creek tributary to San Lorenzo River. To be diverted in Rancho Canada del Rincon for irrigation purposes on 700 acres in Sections 20 and 21, T 10 S, R 2 W, M. D. M. and Ranchos Canada del Rincon and Zayante. Estimated cost $10,000.

Application No. 5149 (Santa Cruz County)—Felton Water Co., Felton, Calif., for 0.26 cubic foot per second from Limestone Brook and Scott Creek tributary to San Lorenzo River. To be diverted in Rancho Canada del Rincon, for municipal purposes in Felton, Felton Acres and vicinity. Estimated cost $10,000.

Application No. 5150 (Santa Cruz County)—Felton Water Co., Felton, Calif., for 0.26 cubic foot per second from Limestone Brook and Scott Creek tributary to San Lorenzo River. To be diverted in Rancho Canada del Rincon, for domestic purposes in Sections 20 and 21, T 10 S, R 2 W, M. D. M. and Ranchos Canada del Rincon and Zayante. Estimated cost $10,000.

Application No. 5153 (San Joaquin County)—Theodor Lorenzen, care of Ohm and Raab, 517 E. Market St., Stockton, Calif., for 12.34 cubic feet per second from San Joaquin River tributary to Suisun Bay. To be diverted in Section 22, T 2 S, R 6 E, M. D. M. for irrigation purposes on 987.6 acres in Sections 15, 16, 20, 21, 22, 28, 29 and 32, T 2 S, R 6 E, M. D. M. Estimated cost $16,000.

Application No. 5155 (San Joaquin County)—Island Recl. Dist. 2062, Banta, Calif., for 50 cubic feet per second from San Joaquin River, Old River and Paradise Cut tributary to San Joaquin River. To be diverted at 5 points in El Pescadero Rancho for irrigation purposes on 3938 acres in El Pescadero Rancho.

Application No. 5158 (Mono County)—Lloyd Summers, Mammoth Lake, Calif., for 0.50 cubic foot per second from Dry Creek tributary to Owens River. To be diverted in Section 32, T 3 S, R 27 E, M. D. M. for domestic purposes on tract to be subdivided in Sections 33, 34 and 35, T 3 S, R 27 E, M. D. M. Estimated cost $15,000.

Application No. 5159 (Mono County)—Edson M. Scofield, Mammoth Lakes, Calif., for 0.05 cubic foot per second from Mill Creek tributary to Mammoth Creek. To be diverted in Section 16, T 4 S, R 27 E, M. D. M. for domestic purposes for 12 cabin sites in Sec. 16, T 4 S, R 27 E, M. D. M. Estimated cost $1,000.

Application No. 5160 (Sutter County)—Commercial Investment Co., care of Drury Butler, Court House, Sacramento, Calif., for 1.75 cubic foot per second from Sacramento River tributary to Suisun Bay to be diverted in Sec. 11, T 11 N, R 2 E, M. D. M., for irrigation purposes on 140.07 acres in Secs. 11 & 14, T 11 N, R 2 E, M. D. M. Estimated cost $3.000.

Application No. 5161 (Alpine County)—Pacific Gas & Electric Co., 245 Market St., San Francisco, Calif., for 9,412 acre feet per annum from Deer Creek tributary to N. Fk. Mokelumne River to be diverted in Sec. 5, T 8 N, R 19 E, and re-diversion in Sec. 33, T 8 N, R 16 E, M. D. M. for power purposes in Sec. 24, T 7 N, R 13 E, M. D. M. 14,170 H. P. Estimated cost $600,000.

Application No. 5169 (Nevada County)—C. S. Wheeler, Wheelerville via Reno, Nevada for 49,000 acre feet per annum from Little Truckee River tributary to Truckee River to be diverted in Sec. 4, T 18 N, R 17 E, M. D. M. for irrigation and domestic purposes on 25,000 acres in T 18 N, R 19 & 20 E; T 19 N, R 18, 19 & 20 E; T 20 N, R 19 & 20 E, M. D. M. Estimated cost $500,000.

Application No. 5170 (Nevada County)—C. S. Wheeler, Wheelerville via Reno, Nevada for 500 cubic feet per second from Truckee River tributary to Pyramid Lake to be diverted in Sec. 28, T 18 N, R 17 E, M. D. M. for power and domestic purposes in Sec. 30, T 18 N, R 18 E, M. D. M. 11,023 H. P.

Application No. 5174 (Mariposa County)—Daniel McFarland, Storrie, Plumas Co., Calif., for 2000 cubic feet per second from Merced River tributary to San Joaquin River to be diverted in Sec. 2 (approx. location), T 5 S, R 15 E, M. D. M. for power purposes. 13,750 H. P. Estimated cost $400,000.

Application No. 5175 (Siskiyou County)—John Hodgdon, Box 21, Yreka, Calif., 12.5 cubic feet per second from Middle Fork Humbug Creek tributary to Klamath River to be diverted in Sec. 15, T 45 N, R 8 W, M. D. M. for mining and domestic purposes in Secs. 10, 11 & 15, T 45 N, R 8 W, M. D. M.

Application No. 5176 (Mariposa County)—J. J. O'Connell, care of Claude B. Boyton Co., 119 E. Broadway, Glendale, Calif., for 3600 acre feet per annum of flood waters of W. Fork Chowchilla River tributary to Chowchilla River to be diverted in Sec. 14, T 6 S, R 19 E, M. D. M. for recreational purposes. Estimated cost $110,000.

Application No. 5179 (San Bernardino County)—Thomas O. Williams, Yermo, Calif., for 25 cubic feet per second from Mojave River tributary to Mojave desert to be diverted in Sec. 26, T 10 N, R 3 E, S. B. M. for irrigation and domestic purposes on 2000 acres. Estimated cost $30,000.

Application No. 5180 (San Mateo County)—Islam Redwoods Shrine, care of Francis Keasling, Chronicle Bldg., San Francisco, Calif., for 500 acre feet per annum from Pescadero Creek tributary to Pacific Ocean to be diverted in Sec. 8, T 8 S, R 3 W, M. D. M. for irrigation of golf course, parks and gardens. Estimated cost $25,000.

Application No. 5181 (Butte County)—W. C. Stevens, care of Polk & Robinson, Chico, Calif., for 2000 acre feet per annum from Butte Creek tributary to Sacramento River to be diverted in Sec. 4, T 21 N, R 2 E, M. D. M. for irrigation purposes on 1,740 acres in Secs. 16, 18, 19, 20 & 21, T 21 N, R 1 E, M. D. M.

Power Developments

The Federal Power Commission at its August meeting voted to authorize the issuance of the following licenses and permits affecting projects in the western states.

Project No. 662. To Best Flume & Power Company, of Pinedale, Wyoming, a license for 15 years for a constructed project on Pine Creek, in Sublette County, Wyoming. The principal works of the project consist of a head gate diverting water through a flume about 1-10th mile in length to a power house, and a transmission line about two miles in length. The installed capacity is 65 horsepower, and the developed power is supplied to the town of Pinedale for electric lighting.

Project. No. 683. To Prairie Power Company of Prairie City, Oregon, a preliminary permit for two years for a proposed power project on Strawberry Creek, a tributary of John Day River, in Grant County, Oregon, and within the Malheur National Forest.

No. 736. W. R. Vandeveer of Ophir, Colorado has applied for a license for a constructed project on Bilk Creek in Montezuma National Forest, San Miguel County, Colorado. The project is less than 100 horsepower, and consists of a diversion dam, flume, pipe line, power house with a four-foot Pelton wheel, and necessary air-compressor machinery. The energy is used for mining purposes.

The Commission also authorized the application of the Los Angeles County Flood Control District for a right of way for a reservoir authorized by the Interior Department under the provisions of the acts of 1891 and 1898 on San Gabriel River, California, at the Twin Forks Site.

Permits Issued

Among the more important permits to appropriate water issued by the Department of Public Works, Division of Water Rights of California, during the month of August, 1926, were the following:

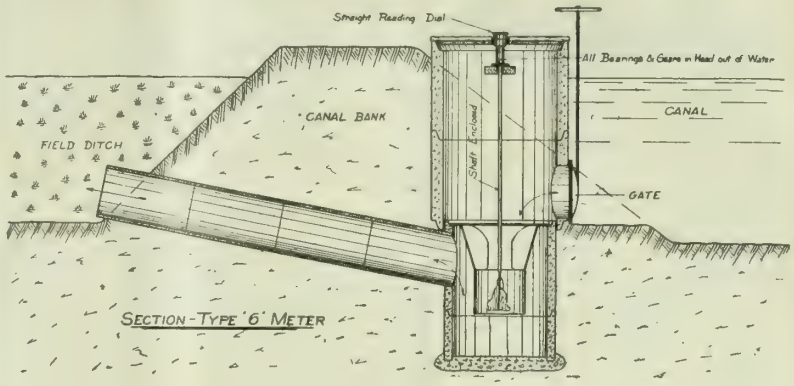
Permit No. 2587, Application No. 4926 (Nevada County) Issued to Jonas Hirsch, Reno, Nevada, August 10, 1926 for 0.37 cubic foot per second from Juniper Creek in Sec. 34, T 18 N, R 17 E, for irrigation of 30 acres, for domestic and fire protection near point of diversion. Estimated cost $2,000.

Permit No. 2588, Application No. 5000 (Nevada County) Issued to Jonas Hirsch, Reno, Nevada, August 10, 1926 for 1 cubic foot per second from Juniper Creek in Sec. 34, T 18 N, R 17 E, for power purposes in Sec. 34, 26 T. H. P. to be developed.

Permit No. 2589, Application No. 4920 (Mono County) Issued to Lloyd Summers and U. S. Forest Service, Bishop, Calif., August 11, 1926 for 0.15 cubic foot per second from two unnamed springs in Sec. 4, T 4 S, R 27 E., for domestic purposes at Mammoth Camp Resort, Mammoth Hotel and U. S. Rangers Station. Estimated cost $5,000.

Permit No. 2590, Application No. 4942 (Contra Costa County) Issued to Rindge Land Reclamation Dist. No. 2036, Stockton, Calif., August 12, 1926 for 30.8 cubic feet per second from Old River, Rock Slough & Indian Slough, movable points of diversion in Secs. 1, 11, 12, T 1 N, R 3 E, Sec. 36,

The RELIANCE METER



THE "Type 6" Reliance Irrigation Meter offers you standardized permanent construction at a very low first cost. Their sustained efficiency with a minimum of upkeep has been proven by 12 years usage. Cut shows installation of the 4 sec. ft. size in 24 and 30-inch concrete pipe. This is the standard type of setting adopted by many irrigation districts in Texas and elsewhere who are now equipping all their deliveries with this device. The "Type 6" meter is furnished in sizes ranging from ½ up to 16 sec. ft.

T 2 N, R 3 E; Secs. 5, 6, 7, 8, T 1 N, R 4 E, and Sec. 31, T 2 N, R 4 E, for irrigation of 2464.6 acres near point of diversion.

Permit No. 2591, Application No. 4943 (San Joaquin County) Issued to Rindge Land Reclamation Dist. No. 2037, Stockton, Calif., August 12, 1926 for 85.45 cubic feet per second from San Joaquin River, Disappointment Slough, 12 Mile Slough and 14 Mile Slough, movable point of diversion in Secs. 1 & 12, T 2 N, R 4 E, and Secs. 5, 6, 7, 8, 9, 10, 11, 13, 14, 15, 16, 17, 18, 20, 21, 22, 23, 24, 26, 27, 28, 29, T 2 N, R 5 E, for irrigation of 6837.26 acres near point of diversion.

Permit No. 2592, Application No. 4944 (San Joaquin County) Issued to Rindge Land Reclamation Dist. No. 2038, Stockton Calif., August 12, 1926 for 71.74 cubic feet per second from Empire Cut, Whiskey Slough & Middle River in Secs. 1, 2, 3, 10, 11, 12, 13, 14, 15, 16, T 1 N, R 4 E and Secs. 5, 6, 7, 8, 9, 16, 17, 18, T 1 N, R 5 E, for irrigation of 5739 acres near point of diversion.

Permit No. 2593, Application No. 4945 (San Joaquin County) Issued to Rindge Land Reclamation Dist., No. 2039, Stockton, Calif., August 12, 1926 for 78.6 cubic feet per second from Trappers Slough and Middle River, movable points of diversion in Secs. 13, 14, 15, 16, 21, 22, 23, 24, 25, 26, 27, 35, 36, T 1 N, R 4 E, and Secs. 16, 17, 18, 19, 20, 21, 29, 30, T 1 N, R 5 E, for irrigation of 6289.1 acres near point of diversion.

Permit No. 2595, Application No. 5063 (San Joaquin County) Issued to Antonio Sanguinetti, Stockton, Calif., August 14, 1926 for 0.72 cubic foot per second from San Joaquin River in Sec. 5, T 1 S, R 6 E, for irrigation of 58.9 acres near point of diversion. Estimated cost $3,700.

Permit No. 2596, Application No. 4951 (Butte County) Issued to Herbert W. Barmann, Chico, Calif., August 16, 1926 for 10 cubic feet per second from Canal of Drainage Dist. No. 100 in Secs. 30 & 31, T 19 N, R 2 E, for irrigation of 1293 acres near point of diversion. Estimated cost $1000.

Permit No. 2601, Application No. 5018 (Trinity County) Issued to Viola A. Dailey, Burnt Ranch, Calif., August 25, 1926 for 1.25 cubic foot per second from Panther Creek in Sec. 12, T 6 N, R 6 E, H. M. for use for domestic and irrigation of 100 acres in Sec. 18, T 6 N, R 7 E. Estimated cost $3,000.

Permit No. 2602, Application No. 4911 (Butte County) Issued to Charles Bloom, Richvale, Calif., August 25, 1926 for 2.65 cubic feet per second from Ditch "B" of Drainage Dist. No. 200 in Sec. 22, T 19 N, R 2 E., for irrigation of 105.9 acres of rice near point of diversion. Estimated cost $1,000.

Permit No. 2603, Application No. 5064 (San Joaquin County) Issued to John H. Masters, Stockton, Calif., August 25, 1926, for 0.9 cubic foot per second from Burns Cutoff in Sec. 12, T 1 N, R 5 E, for irrigation of 72.4 acres in Sec. 14. Estimated cost $5,000.

Permit No. 2605, Application No. 3883 (San Bernardino County) Issued to Sheep Creek Water Company, Phelan, Calif., August 27, 1926 for 3000 acre feet per annum from Sheep Creek surface and subsurface flow in Secs. 9 & 10, T 3 N, R 7 W. for domestic and irrigation of 1920 acres near point of diversion. Estimated cost $150,000.

OREGON

Among the more important applications for permit to appropriate water filed in the office of Rhea Luper, State Engineer of Oregon, during August, 1926, were the following:

Frank C. McColloch, Trustee of Baker, covering the appropriation of water from Pine Creek for the construction of a reservoir for placer mining, at an estimated cost of $3,000.

Walter E. Hardy, of Portland, covering an appropriation of water from a tributary to Pacific Ocean, for auto camp purposes in Lincoln County.

Elmer E. Fletcher of Almira, Lane Co., covering an appropriation of water from Hannavan Creek and a canyon, tributary to Long Tom, for irrigation of 40 acres.

Harry J. Warner, of Portland, covering an appropriation of water from a stream tributary to Sandy River for domestic use, at an estimated cost of $350.

Edward W. Hartley, of Richland, Baker Co., covering an appropriation from waste water for irrigation from Eagle Creek, for supplemental irrigation, domestic and stock use, for forty acres.

Oregon State Highway Commission, covering an appropriation of water from several springs, tributary to Powder River. Not yet estimated.

J. H. Donaldson of 92nd St., Portland, covering an appropriation of water from Rock Creek (Clackamas River) for irrigation, power and fish propagation.

City of Milton, covering an appropriation of water from Walla Walla River, for power and municipal purposes.

Rainbow Mining Company of Rye Valley, Malheur County, covering an appropriation of water from two springs for mining and domestic purposes, at an estimated cost of $2500.

Omer Hastie, of Woodburn, covering an appropriation of water from Butte Creek, for irrigation of 15 acres, at an estimated cost of $250.

Amos Burns, of Mulino, covering an appropriation of water from Little Cedar Creek for irrigation of 10 acres, and domestic use, at an estimated cost of $300.

Virlin E. Brown of Tillamook, covering an appropriation from spring and creek for domestic use, at an estimated cost of $175.

M. P. J. & J. P. J. Barry of Lakeview, covering an appropriation of water from spring for stock use.

The Oregon State Game Commission, covering an appropriation of water from Oak Spring, for trout hatchery and feeding ponds, at an estimated cost of $500.

The American Natl. Bank & Henry C. Judd of Pendleton, covering an appropriation of water from Sutter Creek and flood water, for irrigation of 60 acres, at an estimated cost of $300.

Louisa Segui, of Rte. 3, The Dalles, covering an appropriation of water from a spring, tributary of Mill Creek, for domestic use and irrigation of 2 acres.

George A. Martin of Riverton, Coos Co., covering an appropriation of water from creek trib. to Coquille River, for domestic supplies, at an estimated cost of $500.

D. N. Cotton, of Myrtle Point, covering an appropriation of water from two springs, for domestic use, at an estimated cost of $150.

Ernest and Pansy Applegate and J. L. Grubb Estate, of Ashland, for the construction of a reservoir, for the waters of Ice House Creek.

HYDRAULICS

By Joseph N. Le Conte
Professor of Engineering Mechanics, University of California

A thorough Textbook on the theory of hydraulics and on the principles of hydraulic machinery. This book aims to show the student of hydraulics and irrigation how problems in hydraulic engineering can be reasoned out and solved by practical appeal to first principles.

348 pages. 5¾ by 9. Fully illustrated with diagrams and charts. All orders should be accompanied with cash. Allow ample time for shipment from the publishers. $3.00 postpaid.

Los Angeles, California

Legal and Judicial

(*Continued from Page 44*)

Supreme Court Rules on Appropriation of Spring Water

Waters of a spring flowing down a well defined stream are subject to appropriation.

In the case of Allison v. Linn, 247 Pac. Rep. 730 (Wash. July 8th, 1926) the Supreme Court of Washington reverses a finding of the trial court concerning the appropriation of water from a spring.

The trial court stated in its opinion: "My conclusion is that there is not a flowing stream. It does not lead to anywhere. . . . . A small stream of water from the spring comes over onto the land of appellant for a certain distance . . . and seeps away into the ground at that point . . . . I think a flowing stream must flow on down to a certain place and have a mouth somewhere. . . . . ."

The Supreme Court in answer to the remarks of the trial court says:

We are afraid the learned trial court was guided too much by what he saw at the dry season of the year, and was temporarily misled by the idea that in order for there to be a stream in a legal sense it must flow on down to a certain place and have a mouth somewhere. But even if we take its view of the flow, it would seem that at the time he visited the premises there was a well defined stream for about 200 feet in appellant's lands. The fact, if it be such, that the waters then disappeared into the ground, or that there was no mouth to the stream, as suggested by the court, ought, it seems to us, make no difference . . . . All . . . these facts, together with what the court found by a view of the spring, would seem to require a holding that there was a well defined stream running upon and over at least a portion of appellant's land. . . . ."

Supreme Court Rules on Springer Ditch Co. Case

Owner of a reservoir is required to use ordinary care in inspecting and maintaining a dam.

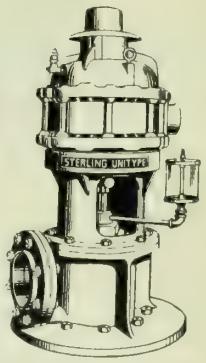
In the case of Springer Ditch Co. v. Wright, 247 Pac. 270, the Supreme Court of New Mexico holds that the case being based upon the question of negligence in inspecting and maintaining a dam and the court finding such negligence, the question of the rule of liability applicable to one who stores waters for irrigation, and as to whether the doctrine of res ipsa loquitur may be invoked cannot be considered by the Supreme Court.

The Supreme Court stated:

"Rulings excluding, as mere offers of settlement, evidence relied upon as admissions were considered in two recent decisions of the court. . . . . It is quite apparent that the exclusion of the conversation was warranted under these decisions. We think also that the exclusion of the writing must be sustained. . . . ."

Sterling Quality CENTRIFUGAL PUMPS

VERTICAL PUMPS for Surface or Pit Pumping. Same construction features as the split case Centrifugal Pump. Sizes—1½ in., 2 in., 3 in., 4 in., 5 in., 6 in., & 8 in. Send for bulletin No. 21.



Sterling Unitype Drive
The Original

Deep Well Turbine Pumps

Made for the following well diams.: 4 in., 6 in., 7 in., 8 in., 10 in., 12 in., 14 in., 16 in., 18 in. and 20 in. Capacities 20 G.P.M. to 4,000 G.P.M. Send for Bulletin No. 16.

NOTE—The motor drive for this vertical pump interchanges with the deep well Turbine Drive.

Manufactured by

Sterling Pump Works, Inc.

Stockton, California

Member of Western Irrigation Equipment Association.

AMONG OUR CONTRIBUTORS

Editorial Jottings About Current and Forthcoming Feature Articles, Dealing With Practical Problems of Hydraulics, and the Men Who Have Written Them

THE COLLEGE PROFESSOR holds the most prominent place in this issue of MODERN IRRIGATION, and he shows himself not the visionary, absent-minded fellow he is represented to be in the humor columns and sometimes in literature, but rather the alert, practical man ready and able to cope with the perplexities that meet the irrigators in their work.

S. H. Beckett, author of "Anticipating the Problems of Tomorrow's Irrigators," is Associate Professor of Irrigation Investigations and Practice, College of Agriculture, University of California. He is a former member of the U. S. Reclamation Service and just prior to his association with the university, was identified with the Department of Agriculture. Professor Beckett keeps in unusually close touch with the irrigators of the west and is especially fitted to write of their needs. His article is the first that MODERN IRRIGATION is presenting to give its readers an outline of what the western colleges are doing for the industry.

W. L. POWERS, who writes the article on feasibility surveys in connection with irrigation projects, is no stranger to the readers of MODERN IRRIGATION. Not only has he been presented as one of the advisors of the journal, but he also contributed last fall a very able article on "A Constructive Irrigation Program for Oregon." Professor Powers is Chief of the Division of Soils at the Oregon State Agricultural College. He has been an active member of the Oregon Reclamation Congress since its beginning in 1910 and is at present its secretary. He has also been secretary of the Oregon State Drainage Association since its formation ten years ago.

H. E. ERDMAN, who discusses the question of farm tenancy, is a member of the faculty of the College of Agriculture, University of California, in the department of Agricultural Economics. He is a graduate of the South Dakota College of Agriculture and Mechanical Arts, and has a Ph. D. degree from the University of Wisconsin. From 1912 to 1914 he was deputy state dairy expert in South Dakota. In 1917 he went to the Ohio State University as Assistant Professor of Rural Economics. He remained there until 1922, and during part of this time, in addition to his teaching, had charge of the Costs of Marketing Division of the Bureau of Markets and Crop Estimates, a bureau of the U. S. Department of Agriculture. In 1922 he came to the University of California as Associate Professor of Rural Institutions and was appointed to his present position there as Professor of Agricultural Economics during this year. Professor Erdman was one of the lecturers at the first session of the American Institute of Co-operation, held during July and August, 1925.

F. W. SLATTERY, who tells of some of the problems encountered in the drainage of the Imperial Valley, is the engineer in charge of the very extensive drainage operations there. MODERN IRRIGATION hopes to have an account of other phases of Mr. Slattery's work in some future issue of the journal.

RAYMOND A. HILL graduated from the University of Michigan in 1914 with the degree of Bachelor of Civil Engineering, and was given the degree of Civil Engineer in the same university in 1922.

From 1909 until 1917, except while at the university, he was with the U. S. Reclamation Service in various capacities including surveys, design, special investigations, and supervision of construction of irrigation works in Colorado, Utah and Arizona.

From May, 1917, to August, 1919, he served in the United States and France as an engineer officer in the United States Army.

Since 1917 he has been associated with Quinton, Code and Hill, Consulting Engineers of Los Angeles, and has been engaged principally upon various irrigation projects in the Southwest and Mexico. During the last year he made a detailed investigation of the irrigation requirements and the economic feasibility of the project on the Rio Mayo in Sonora, Mexico, which has been fathered by Ex-President Obregon, and upon which the Federal Government anticipates spending about $10,000,000 in accordance with its program of irrigation development. In connection with this work, Mr. Hill was thrown in close contact with the members and engineers of the Comision Nacional de Irrigacion of Mexico, and had the opportunity to have several conferences with President Calles.

Mr. Hill is a member of the American Society of Civil Engineers and is president of the Los Angeles section of the society.

JAMES GRAVES SCRUGHAM is more popularly know as the "engineer governor" of Nevada. He received his B. M. E. from the University of Kentucky in 1900, finishing with his M. E. in 1906. He then went into the professional engineering field with a group of three different organizations. From 1903 till 1914 he was professor of mechanical engineering at the University of Nevada. Since 1914 he has been the dean of the Engineering College of the University of Nevada. In 1917 he became state engineer of Nevada, and in 1919 he was made Public Service Commissioner. During the war he served as chief of carriage section, production and artillery divisions of the Ordinance department in 1918. That he has had a wide range of experience in public affairs is further shown by the fact that he served on boards of the San Francisco and San Diego expositions of 1915. In 1916 he was made an associate member of the U. S. Naval Consulting Board. The American Legion made him national vice-commander for 1920-21. Since his election to the governorship of Nevada he has given his time to bring Nevada from a state that people used to dread to cross to a veritable land of comforts through his engineering knowledge and application.

THIS MONTH'S COVER has a particular appeal to the waterworks engineer. The photograph shows the Soledad siphon section of the Los Angeles aqueduct. Countless difficulties were encountered in laying this giant pipe line and engineering problems apparently insurmountable were solved. MODERN IRRIGATION is indebted to the U. S. Electrical Manufacturing Company, Los Angeles, for this illustration.

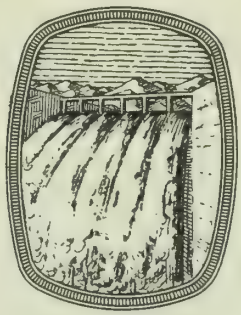
C. B. JACKSON

Chairman of the California Section of the American Water Works Association, which is holding its seventh annual convention at San Diego October 28, 29 and 30. Mr. Jackson has for many years been general manager of the Fresno City Water Corporation, which was recently purchased, with the Chico Water Supply Company, Bakersfield Water Supply Company and Visalia Water Supply Company, all of California, by the Federal Water Service Corporation of New York. Mr. Jackson was elected vice president and general manager of the combined properties in October.

MODERN Irrigation
The Magazine of Applied Hydraulics



Volume II OCTOBER, 1926 Number 10

Our Debt to Water Works

WHILE the function of this department of the magazine is, as its usual monthly title line indicates, to report the "progress of irrigation," it seems fitting that no little space in this issue should be devoted to a discussion of the progress of *water works*. As a matter of fact, development in the two fields is, to a large extent, interrelated in the west, as pointed out on another page of this issue; and whether the subject matter be water works or irrigation and reclamation the story should be of interest to nearly all readers of the magazine.

Climaxing seven years of co-ordinated effort and co-operation in all matters affecting water works development, the California Section of the American Water Works Association is meeting at San Diego in annual convention Oct. 28, 29 and 30. That the purposes of the association have been and are being accomplished, in large measure, insofar as the Pacific Coast is concerned, will be evident to those who attend the convention and follow its program closely; for that program will constitute a symposium of western water works progress during the current and preceding years.

A glance backward is necessary to visualize in proper perspective the development of water works in this country. Until 1870 there were no water filtration plants in the United States as the term is now understood, although some of the surface supplies then in use were passed through so-called filters or strainers of gravel, charcoal or sponge. Bridging fifty-five years of progress and reviewing developments of the last year, one learns that there were about 587 rapid and about 47 slow sand filters in use, with a total capacity of approximately 5,000 million gallons a day.

Chlorination dates from 1908. It is now used on nearly all surface supplies, whether filtered or not. Credit for the first systematic use of chlorine for treatment of a large supply of water is due to Sir Alexander Houston when, in 1904 and 1905, a dosage of one part per million of chlorine was applied in the form of sodium hypochlorite. In 1913 apparatus for applying liquid chlorine from cylinders had been perfected and put on the market. In 1924 over 3,750,000,000 gallons per day were being treated in more than three thousand cities and towns in the United States. There are now 6,000 installations of chlorinating equipment in use in the country and it is estimated

See Page 33 for First Issue of "Western Waterworks" ☛

that 70 per cent of the population of North America are drinking water treated with liquid chlorine.

The great service to mankind involved in this development is of course well known to the water works and sanitary engineers. The large reduction in typhoid fever in the United States has been largely due to the measures for safeguarding domestic water supplies described in the foregoing paragraphs. To the introduction of new water supplies and the improvement of both old and new systems by means of sanitary protection, filtration and chlorination the heavy reduction —and in many places the virtual disappearance— of typhoid fever is largely due. It is well to recall that no longer than 30 years ago typhoid death rates of 20 to 100 per 100,000 were common with rates in bad years in the most afflicted cities running higher.

The visitor at the San Diego convention of the California Section of the American Water Works Association will not only be impressed with the way in which the water works have made good with mankind in lessening the death rate of urban communities, but he will—if his experience in the profession dates back many years—be impressed with the purely physical development of water works; as, for instance, the development in pumping equipment, the wonders that research on pipe protection has wrought, the development of the water meter and other accessories to the modern water supply system. A panorama of this kind of development will unfold before the visitor to the exhibits of manufacturers. These will form an important educational adjunct to the convention.

Waterworks officials find that a part of the value of attendance at the annual meetings comes from this exhibition of waterworks equipment and supplies. It is an old feature with the parent organization and is of such demonstrated usefulness to the buyer and maker alike that an ernest endeavor, helped by long experience, results annually in an exhibit surprising to those who see for the first time, brought together in one place, the industrial products now available for waterworks plants.

Without doubt the American Water Works Association performs a real service for the most important public utility business in America. The demand for water is growing even faster than the increase in the population of the country would indicate, because a steadily increasing proportion of the population is living in communities served by waterworks and with more industries and better living conditions the consumption per consumer is mounting continuously. The association is serving a big purpose in meeting the demands of this growth "through the advancement of knowledge of the design, construction, operation and management of waterworks, and the encouragement by social intercourse among its members of a friendly exchange of information and experience.

One of the biggest consolidations of recent years affecting California water companies was announced at press time. Reports from New York City state that for an estimated consideration of $3,500,000 the Federal Water Service Corporation has acquired the Fresno Water Corporation, Chico Water Supply Company, Bakersfield Water Supply Company, and the Visalia Water Supply Company.

These four water companies were actively connected with the pioneer struggles of these San Joaquin Valley cities in their development from the plains. The largest company of the four is the Fresno City Water Corporation, formerly a part of the Western Power System, and the consideration for the transfer of this property alone was said to be $2,500,000.

WESTERN WATERWORKS

IS HERE

WITH this issue MODERN IRRIGATION introduces the new publication WESTERN WATERWORKS—a magazine within a magazine—devoted solely to the interests of the waterworks industry of the west. It will appear, for the time being, as a supplement to MODERN IRRIGATION.

Turn to Page Thirty-three

See Page 33 for First Issue of "Western Waterworks"

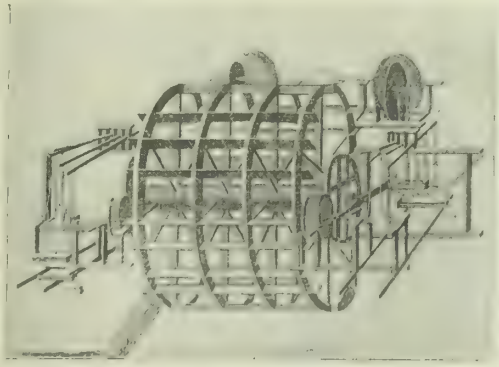
Water works under the Ancient London Bridge, 1588, from an old print

Looking Backward

Over 344 Years of Waterworks History

IN 1852, Peter Morris, a free citizen of Holland, went to London and designed and built a water works which was put under the arches of Old London Bridge which at that time was a roadway with houses built on each side like a city street. This water works was operated by undershot water wheels that drove four pump cylinders from each end of the wheels. The design has come down to us in its original form as shown in the illustration copied from the original copper plate. The exact specifications to which the pump cylinders were made have been hidden by the dust of the intervening years.

This water works pumped water from the Thames through pipes of lead and supplied various houses in the ancient city. It required, however, four more relay pumps worked by horses to supply the outlying districts. This works was enlarged from time to time until it became, by successive improvements, a unique and truly ingenious and powerful piece of mechanism—wonderful for that age. The city of London was chiefly supplied with water by this works for a long period of time, until it was removed by Act of Parliament in 1822.



Water wheel of the London Water Works

A Snowball Growth

THERE has been a tremendous effect produced by the development of water works systems, and a glance backward will show how comparatively rapid this development has been. At the close of 1800 there were seventeen waterworks in the United States; this doubled to 34 in 1825 and there were 100 in 1850. This had increased to 243 in 1875, after which there was a very rapid growth and 1000 waterworks were recorded in 1885. In the next ten years this had tripled and by 1925 over 10,000 water works were registered. The accompanying illustrated article, secured through the courtesy and co-operation of "Oil-Power," published by the Standard Oil Company of New York, gives briefly some of the outstanding events in early water works development. The reader will be impressed with and feel grateful for the early work of the men who not only developed this art, but who worked on the early steam engines and in the machine shops in which these aids to civilization were produced.

First Water Works in America

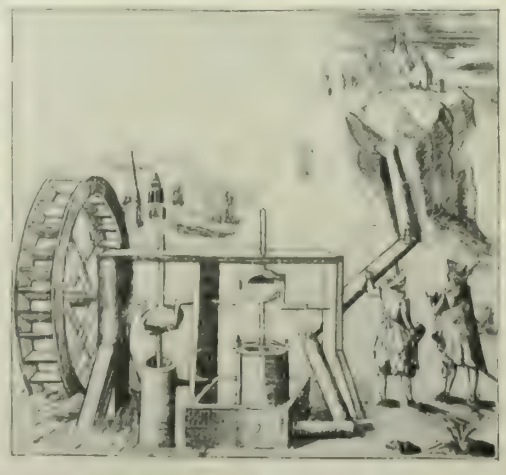
The early settlers who founded Bethlehem, Pa., in 1741, selected a site near a sparkling spring to insure a convenient and abundant supply of pure cool water. When the first log cabins were built each family supplied itself by hand with its water requirements, but later, as the settlement grew, the water distribution was organized and individual needs were distributed to the log cabins of the community by water carriers or haulers formally delegated for the purpose, one of whom, history relates, in the faithful discharge of his duties had the mishap to upset his cart and fracture his arm.

In 1751, a new settler arrived by the name of Hans Christopher Christiansen, a millwright by profession and by nature a mechanical genius. In 1754, due to the inventive ability of this young Dane, he was given the job of supplying the community with water otherwise than by manual distribution. A building 19x22 feet was built to house a pump made of lignum-vitae with a cylinder 5 inches in diameter. This pump was driven by an undershot water wheel. The water supply was forced through pipes up a hill to a reservoir. The pipes were hemlock logs with a hole bored through them.

When the pump was first started water was thrown over the adjoining houses much to the wonder and admiration of the members of the community and of visitors who came for the occasion. Many interruptions in the service were caused by bursting wooden pipes, and to overcome this difficulty a 1½-inch lead pipe was made of sheet metal, soldered along the edges and imbedded in a cement of pitch and brick dust and all laid in a gutter of burnt brick.

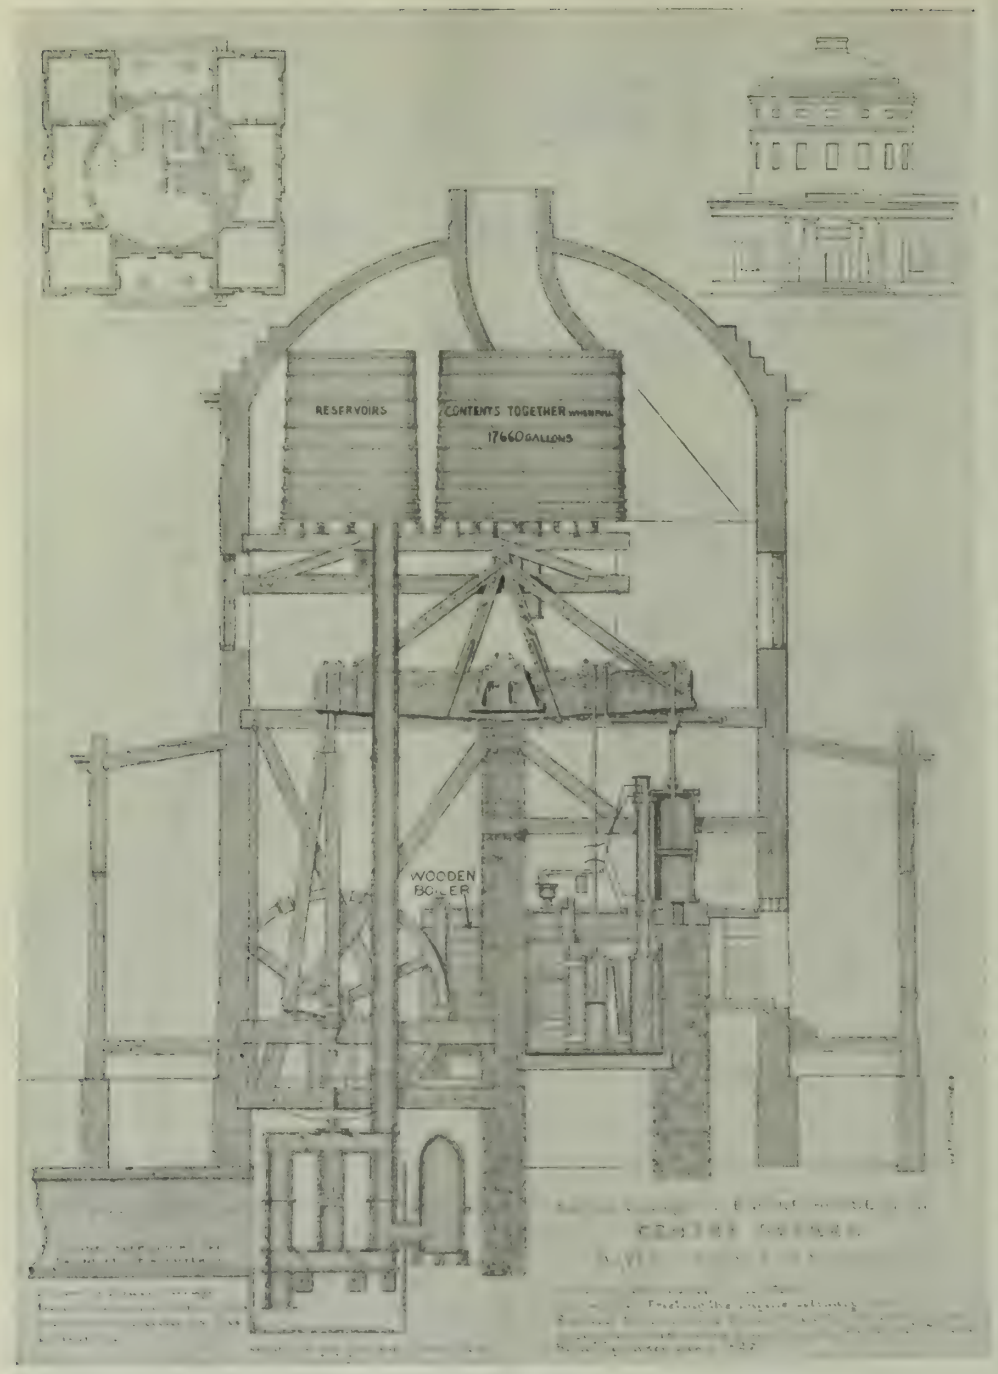
Improves on Original

Christiansen commenced a second and



Undershot water wheel working two stage force pump for supplying water to a town. From Zeising, 1607.

See Page 33 for First Issue of "Western Waterworks"



Plan of the Centre Square Water Works, Philadelphia, 1799. From the Transactions of the Franklin Institute, Philadelphia, Vol. 25, 1853

more powerful pump in 1761. This consisted of three single acting force pumps of iron 4-inch "caliber" and 18-inch stroke worked by a triple crank which was forged by the resident blacksmith, Stephen Blum. This triple throw shaft was ever the just subject of pride as to ingenuity of workmanship. The undershot water wheel was 18 feet in diameter and 2 feet clear in the buckets.

On the water wheel shaft was a "wallower of 33 rounds" which geared into a spur wheel of 52 cogs attached to the crankshaft of the triple pump. The crossheads were made of wood and worked in a vertical grooved wooden frame. This pump could force water 112 feet and it supplied water to 7 reservoirs placed at strategic places around the little town, such as in front of the Widow's house, in front of the Sun Tavern, at the apothecary's, at the stable and hattery in the rear.

Thus was maintained a very complete system of water delivery in Bethlehem during the early days of the Republic which impressed visitors with astonishment and admiration. This first pumping station was visited by the Governor of the State, by the Governor of South Carolina, by the Governor-General of the Danish West Indies, by John Adams, General Washington and many other distinguished men of the day.

Iron pipes were introduced in 1813. In 1832 the triple pumps after a service of 70 years were supplanted by a double acting pump of large dimensions, being 5-inch caliber and 36-inch stroke, and this in turn was replaced by a steam pump in 1868.

Water Works of New York

During the days of the Indians and the first Dutch settlers in Manhattan fresh water was secured from numerous springs, ponds and brooks on the island and from shallow wells by means of buckets raised by ropes or pulleys, or by long balanced poles. The water thus secured was pure except near the shores of the island where salt water percolated through, rendering it unfit for cooking and drinking purposes. As the colony grew, public wells were sunk in the middle of the most important streets, the first well being sunk about 1658.

In 1731 when the town consisted of 1,200 houses and 8,628 people, the Council purchased its first fire engine from England, two of them being ordered. This raised the important question of adequate water supply in order to meet the demands of these engines for fire fighting purposes and this led to sinking an additional number of wells to furnish water for domestic purposes and also for use in case of fire.

The primitive buckets at the wells were gradually replaced by pumps. One of the most famous of these was known as the "Old Tea Water Pump," first mentioned in 1748. This pump was placed over a spring of pure water and the surroundings became famous as a resort where tea and

Bored logs which carried Manhattan water

See Page 33 for First Issue of "Western Waterworks"

stronger beverages could be obtained.

New Water Works Proposed

In 1774 a proposal for constructing a water works was made to the Common Council; Christopher Colles, an English engineer drew plans for a reservoir into which water was to be pumped from wells by means of a steam engine, the water to be then distributed by pipes leading along the main street. The Common Council accepted this proposal. Some property at the corner of Broadway between Pearl and White Streets was set aside. A large well was sunk and a Newcomen engine was ordered from England.

This works was put in operation in 1776 at the opening of the Revolutionary War. The plant, however, was not large enough to supply the needs of the town—war demoralized everything and the entire enterprise was abandoned. After this early attempt several other proposals were made from time to time, but it was not until an epidemic of yellow fever forced the question of an adequate water supply that it was practically handled by the Manhattan Company, who secured a charter in 1799 to supply the City of New York with pure and wholesome water.

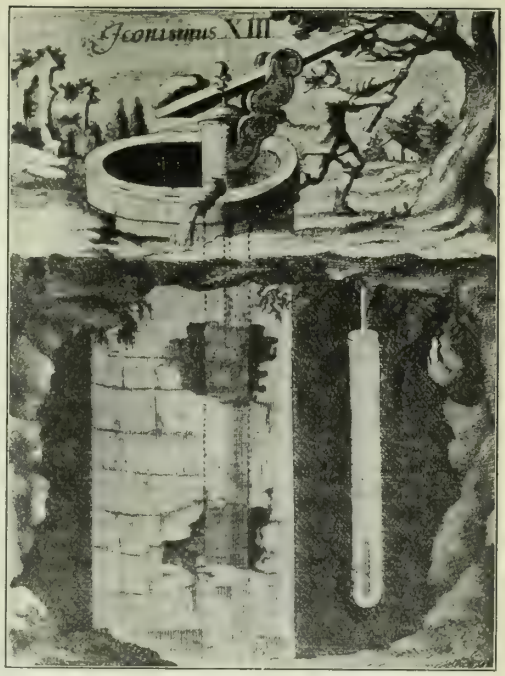
Steam Engine Rejected

The minute book of the Manhattan Company, which is now a valued relic in the possession of the Bank of the Manhattan Company of New York, shows the daily progress of putting in a water supply for the town. A survey of the Bronx was made to see if there was any possibility of bringing water from that source, which might also turn the water wheels to operate the force pumps. This project was not considered practical. On April 17, 1779, the minutes state that information was secured through an authorized source from Bolton and Watt showing the amount of water that could be pumped by various sizes of steam engines and further that an engine sufficient for the needs of the town could be purchased for $12,000.

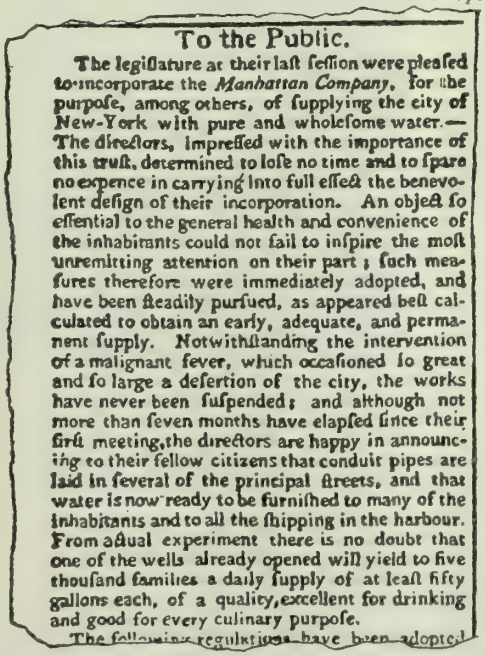
On June 10th of the same year the Board considered an offer made by Nicholas Roosevelt to purchase a steam engine. Nicholas Roosevelt at that time had built an engine from a model of Hornblower's atmospheric engine and had built steam engines for various other purposes. The offer for this engine was not accepted by the Board although Roosevelt undertook to operate his engine for a period of time.

On June 17th of the same year the Board authorized that horses be used to work the pumps. These pumps were later placed in a house 12 feet square fronting on Cross Street on the corner of Little Ann and Reade Streets; eight horses were purchased and a plant was put in operation during 1800 at which time New York had a population of 56,000 people. Water was delivered to houses of subscribers through wooden pipes used as mains to which were connected lead pipes that ran into the individual houses. The water rate for each house was $5.00 per year for each fireplace in the house. Vessels in the harbor were supplied at 20 cents per hogshead.

After this horse operated plant had been in use for some months John Stevens offered to erect and maintain a steam engine in the house then occupied by the horse operated pumps. His proposition was accepted, the minutes specifically stating that the engine was on trial and could be removed at any time, and that the company was not obligated to purchase. This engine operated a pump that handled one-half million gallons in 24 hours. The engine having proven acceptable, the Board of Directors purchased it for $6,000. Six months' expense in operating this engine is shown by the following bill:



Hand operated water pump. From P. Gasparis Schotti, 1657



To the Public.

The legiſlature at their laſt ſeſſion were pleaſed to incorporate the *Manhattan Company*, for the purpoſe, among others, of ſupplying the city of New-York with pure and wholeſome water.—The directors, impreſſed with the importance of this truſt, determined to loſe no time and to ſpare no expence in carrying into full effect the benevolent deſign of their incorporation. An object ſo eſſential to the general health and convenience of the inhabitants could not fail to inſpire the moſt unremitting attention on their part; ſuch meaſures therefore were immediately adopted, and have been ſteadily purſued, as appeared beſt calculated to obtain an early, adequate, and permanent ſupply. Notwithſtanding the intervention of a malignant fever, which occaſioned ſo great and ſo large a deſertion of the city, the works have never been ſuſpended; and although not more than ſeven months have elapſed ſince their firſt meeting, the directors are happy in announcing to their fellow citizens that conduit pipes are laid in ſeveral of the principal ſtreets, and that water is now ready to be furniſhed to many of the inhabitants and to all the ſhipping in the harbour. From actual experiment there is no doubt that one of the wells already opened will yield to five thouſand families a daily ſupply of at leaſt fifty gallons each, of a quality, excellent for drinking and good for every culinary purpoſe.

The following regulations have been adopted

Newspaper notice of formation, about April, 1799, of the Manhattan Company (predecessor of the Bank of the Manhattan Company) to supply water service to New York City.

May 1st to Nov. 1st, 1802	
Coal and carting, etc., (supposed sufficient for nine months)	$2,888.39
Attending to engine	823.70
Blacksmith's bill for repairs of horse pumps, pumps, engine, etc.	129.29
Tallow, spun yarn, leather, candles, etc.	143.28
Making a total of	$3,983.66

Used Tallow Lubricant

This last item is of particular interest as it includes the tallow lubricant for the engine. The spun yarn was used for packing the joints of the pipes and possibly also for stuffing box glands. Leather could have been used for repairing the harness and could also have been used for packing the steam piston as well as water plunger, a method in use in the early days of James Watt.

The first chief engineer of the Philadelphia Water Works reported this information: "This New York Water Works engine has been built upon the principle of Bolton and Watts double engine without any variation. It has

Irrigation and *Waterworks*

Go Hand in Hand in the Forward March of Civilization

An Article About the "California Section"

By HINDA TEAGUE HILL

WATER, and still more water, has been the ever-increasing demand that has marked the first quarter of the twentieth century. Farm lands and cities alike call for water. With the passage of the National Reclamation Act, in 1902, the government undertook the development of projects not feasible by private, corporate, district or state enterprise, leaving to these smaller organizations the projects within their financial reach.

Just as the irrigation projects have reclaimed desert lands and have made homes possible in sections hitherto given over to the snake and coyote, so the water works companies have made living easier for the inhabitants of towns and cities. The smaller towns have recognized the fact that they cannot attract larger populations except as they are prepared to furnish water for them. The cities have realized that water mains must be extended to new sections, that existing mains must be replaced by larger ones. According to figures given by the American Water Works Association in 1925, water works investments in the United States are now increasing at the rate of $100,000,000 to $125,000,000 or more a year.

In this great increase the western states have a large share. For the state of California, and to a certain extent for neighboring states, one of the most important factors in recent growth has been the California Section of the American Water Works Association.

S. B. MORRIS
Vice-chairman for 1926 of the California Section, American Water Works Association. Mr. Morris served as secretary and treasurer of the section during 1925.

The American Water Works Association, which had been founded in 1881 and was a flourishing institution, had a gradually growing membership in California—enthusiastic men who felt the need of a state organization as a section of the parent association. They realized what was taking place about them and they had a vision of the future. They wanted an opportunity to meet together, to become acquainted, and to talk over their problems to see if by chance the other fellow had found a solution.

One of the men most closely associated with the present California Section, and perhaps the outstanding figure in its organization and development, a man who for the first six years was a member of its executive board in one capacity or another, is George W. Pracy, now Superintendent of the Spring Valley Water Company, San Francisco. In 1915, while discussing a water problem with two of his associates, he brought up the question of a California section of the American Water Works Association. Shortly after, he learned that still another member of the association, Kenneth Shibley, had the same idea and was waiting for an opportune moment to put it into effect.

During the year these men talked with other available members of the association and found that they were unanimous in their desire to call a meeting and organize a California section. The plan was cut short by the entrance of America into the World War. The matter was dropped for the moment and the organizers all turned their energies to the needs of the country.

First Meeting in 1919

In 1919 the war had come to an end and the leaders of the west were again looking to the development of a great program for their land. It was in that year that all members of the American

PAUL E. MAGERSTADT
The present secretary and treasurer of the California Section, American Water Works Association.

See Page 33 for First Issue of "Western Waterworks"

Water Works Association in the vicinity of San Francisco Bay were called to a preliminary meeting held in San Francisco, and the California Section became a reality. By-laws were drawn up and officers were elected. G. A. Elliott, vice president and chief engineer of the Spring Valley Water Company, San Francisco, was elected the first chairman; Charles Gilman Hyde, professor of Sanitary Engineering, University of California, was made vice-chairman; and George W. Pracy was elected secretary-treasurer.

The first annual convention of the California Section of the American Water Works Association was held in San Francisco, November 13, 1920, with seventy-five present from all parts of the state. It was a one-day session. At the morning meeting E. P. McMurtry, chief engineer of the Krogh Pump and Machinery Company, read a paper on "The Centrifugal Pump;" Ralph Hilscher, of the California State Board of Health, discussed "Chlorination in California;' and O. E. Clemens, water sales manager of the Spring Valley Water Company, presented some very practical ideas on the "Business End of Water Works."

Luncheon was served at the Engineers' Club, and in the afternoon the delegates inspected the properties of the Spring Valley Water Company. At the evening session M. M. O'Shaughnessy, city engineer of San Francisco, discussed the formation of the Marin Municipal Water District, a combination of some twelve towns, united to provide themselves with a domestic water supply. The officers elected for the following year were: Chairman, G. A. Elliott; Vice-Chairman, L. M. Anderson, Comptroller, Public Service Commissoin; Secretary-Treasurer, George W. Pracy.

Los Angeles Host in 1921

Los Angeles entertained the California Section at its second annual convention, October 1 and 2, 1921. Seventy-two were present from all parts of the state. R. E. Andrews, assistant chief engineer, National Board of Fire Underwriters, read a paper on "Fire Protection." "Causes and Prevention of Electrolysis Troubles in Underground Pipe Systems," was the subject of a paper prepared by E. B. Stewart, and read by H. Reinhardt, assistant chief engineer of the East Bay Water Company, Oakland. George Read, superintendent of the Service and Meter Department, Los Angeles, discussed "Water Meters." Then followed a helpful general discussion of water works problems in which a great number of the delegates took part.

In the evening the delegates were entertained at a dinner served at the City Club of Los Angeles, after which William Mulholland, chief engineer of the Los Angeles Bureau of Water Works and Supply, spoke on the "Los Angeles Water Supply." Saturday, the 2nd, was given over to a trip to points of interest in the Los Angeles water system, and luncheon was served in the construction camp at the San Fernando dam. The officers in charge were re-elected, and C. G. Gillespie and F. N. Isaacs were added to the executive committee.

For its third annual session the California Section met with the East Bay Water Company, Oakland, California, on October 26, 27, and 28, 1922, with an increased attendance of 142 "members and guests" registered from all parts of the state. For the first time there was a three-day session, and for the first time, too, the manufacturers, who form the associate membership of the Section,

P. DIEDERICH
Member of the executive Committee, California Section, American Water Works Association.

staged an exhibit of their products. This exhibit has become one of the important features of the conventions in that it has an unusual educational value. The manufacturers have made a point of showing the very latest improvements along all lines, and not only have their equipment there for inspection, but give a demonstration of its application.

The additional sessions in 1922 gave an opportunity for a more varied program and in all eight pepers were presented. Edward F. O'Day, director of publicity, Spring Valley Water Company, discussed "Publicity"; P. W. Stamps, president of the Purchasing Agents Association of Northern California, gave many pointers on "Purchasing"; and Chester Loveland, consulting

JOHN BURT
Member of the executive committee, California Section, American Water Works Association.

engineer, read a paper on "Valuations and Rates."

"Pumping Machinery" was presented by B. R. Vanleer, assistant professor of Mechanical Engineering, University of California, and Charles H. Lee, consulting Engineer, San Francisco, spoke of "Underground Waters." W. F. Langelier, associate professor of Sanitary Engineering, University of California, described the "East Bay Filter Plant"; Charles Gilman Hyde discussed "Standards of Water Bacteria," and C. A. Kofoid, professor of Zoology, University of California, read a paper on "Microscopic Animalculae."

Besides the program there were many delightful entertainment features. The officers elected for the following year were: Chairman, L. M. Anderson, Comptroller, Public Service Commission; Vice-Chairman, Fred J. Klaus, assistant chief engineer, East Bay Water Company; Secretary-Treasurer, S. B. Morris, superintendent and chief engineer, water department, Pasadena; Executive Committee, C. B. Jackson, superintendent, Fresno City Water Corporation, Fresno, and George W. Pracy.

Fresno Gets the Convention

At the fourth annual convention the Association was the guest of the Fresno City Water Corporation, meeting in the American Legion Hall, Fresno, on October 25, 26, and 27, 1923. One hundred and forty-three members and guests registered. The program committee had prepared an even greater variety of subjects for papers and discussions. Ed-

In the Delta County of the Sacramento River. Here water means transportation, irrigation, and protection against the encroaching tides of the sea. This region is famed for its production of fruits and vegetables. Shipping on the waterways of the delta in 1925 was valued at $127,693,000. With water playing so dominant a part in the economic scheme of things, it is no wonder that problems of the sort presented in this article are occupying the forefront of attention among water users along these streams.

Not Half Enough Water, Where Water is *Everything!*—Two Rivers' Epic Problem

By HARLOWE M. STAFFORD

Nothing theoretical or academic about this article! —written for MODERN IRRIGATION *by Water Supervisor Stafford as one of a series being published to show what the California Division of Water Rights is doing for irrigation in the leading irrigation state. In it he has shown how the water users of these two rivers are waging an epochal battle against the lowering water. An intensely interesting document from a human standpoint, it is a revealing description as well of how the State is aiding the water users to work out their problems.*

APPROPRIATIVE and other vested water rights on the Sacramento River between the city of Sacramento and Red Bluff, California, total 6000 second-feet. Water requirements both for irrigation and salinity control in the great and fertile delta of the Sacramento and San Joaquin Rivers, amount to 3500 second-feet or more. An estimated flow of from 3000 to 3500 second-feet in the Sacramento River above Sacramento is needed merely to satisfy navigation requirements. Yet there was an actual available flow in the river at Red Bluff of only 3000 to 3500 second-feet after July first in four of the last seven seasons and a summer flow of the San Joaquin River to the delta of less than 1000 second-feet! This, briefly, tells the story of the Sacramento-San Joaquin water problems.

At this writing, (early autumn in the 1926 season) there is an irrigation draft of close to 4000 second-feet between Red Bluff and Sacramento. With only 3000 second-feet at Red Bluff the excess demands are met by a combined inflow of 500 second-feet from the Feather and American Rivers and a return water inflow sufficient in amount that there still remains about 1300 second-feet passing the city of Sacramento. Navigation in the upper river is greatly impaired and salt water from San Francisco Bay is rapidly encroaching into the delta channels.

These problems are serious and are demanding earnest thought and endeavor from the various interests involved and from the State, for an early solution. The first acute situation to arise was that in 1920. In that year, with the run-off of the San Francisco Bay drainage area only 48 per cent of normal and the largest rice planting in the Sacramento Valley in the history of the industry, the situation was saved through the Emergency Water Conservation Conference, a voluntary organization of water users and state officials, and a Water Master appointed by the conference to regulate the Sacramento River diversions of those signing a Water Users' Agreement prepared by the conference. It was in this year, however, that, as a result of the salinity encroachment in the delta, the famous Antioch suit was instituted. This cost the valley some hundred of thousands of dollars but did not result in a solution or even a basis for a solution of the problem.

1924 Sees Emergency

Following years of more normal stream flow in 1921, 1922 and 1923 came the extremely dry year of 1924, when the

See Page 33 for First Issue of "Western Waterworks"

run-off of the San Francisco Bay drainage was 27 per cent of normal. With the probability for a critical season evident as early as January in that year, a pressure for the initiation of a definite constructive program in the solution of the problems was felt on all sides. This found expression in the first Sacramento-San Joaquin River Problems Conference, which was held in Sacramento January 25th and 26th, 1924, under the auspices of the California Division of Water Rights and the Sacramento Chamber of Commerce.

Through the medium of authoritative papers presented by experts this conference brought out clearly for discussion the many angles to the problems from the standpoint of the up-river water users, the delta irrigators and the navigation, power and industrial interests. A committee known as the Permanent Committee of the Sacramento-San Joaquin River Problems Conference was appointed to "—prepare a program for the co-operation, adjustment, and development of all irrigation, power and navigation interests, with a view to securing the utmost conservation and use of the waters of the Sacramento and San Joaquin Rivers and their tributaries for the protection and benefit of all."

Since the first conference this committee has functioned actively and has proved to be a powerful influence in welding together the divergent interests involved, in bringing about constructive co-operative effort and in preventing litigation in the face of critical situations that have arisen.

Early in 1924 the Permanent Committee, in co-operation with the Division of Water Rights, instituted a definite plan of action to carry through the irrigation season. This called for an agreement among the water users and other interests to provide for a Water

THE SACRAMENTO
Provider—and puzzle of an empire.

Supervisor to be appointed by and work under the direction of the division.

In specifying the functions of such an official there were certain considerations which should be clear. In a previous article of this series* it has been brought out that the ultimate objective of all water legislation and administrative effort is the distribution of the water itself to those having a valid claim upon it; that where the water titles on a stream have been definitely adjudicated, this is readily accomplished through a State Water Master; and that, in striving to consummate the prerequisite clearing of water titles, three courses are open: (1) litigation, (2) the code provisions of the Water Commission Act, and (3) mutual agreement based upon investigations and determination of physical fact.

*See December, 1925, issue of "Modern Irrigation."

In 1925, in the Sacramento-San Joaquin territory, the use of water under the various classes of water rights was about as follows:

For the Sacramento River and tributaries in the valley above Sacramento, old appropriative rights (initiated prior to the Water Commission Act) 620,700 acre-feet.

Appropriative rights under applications to and permits from the Division of Water Rights, 610,200 acre-feet.

Presumably riparian rights 66,100 acre-feet.

Of 227,000 acres irrigated in the delta in 1925, a considerable portion is covered by appropriative filings before the division and practically the entire delta area of more than 400,000 acres claims water under riparian rights. Under such conditions, with litigation naturally repellent, the third of the above mentioned courses becomes the one most practical and applicable to the present case at least for some time to come.

With the facts of water supply, actual water requirements and use definitely established through engineering investigation, experience has proven it perfectly feasible to base thereon mutual agreements, either temporary to tide over an immediate crisis or more or less permanent, under which a Water Master or Water Supervisor may successfully distribute and conserve for the best interests of all, a deficient water supply. The Water Supervisor's authority and bene-

(*Continued on Page 22*)

One of the largest irrigation pumping plants on the Sacramento is this Tisdale plant of the Sutter Basin Company, near Grimes. Its average capacity is 600 second-feet. Records of the Water Supervisor show a diversion of 136,000 acre-feet at this plant in 1925.

"Winning of the West" League Is Answer to Hoover's Plea for Reclamation Team Work

Delegates from All the Western States Meet in Los Angeles and Effect Organization to Promote Broad Program of Water Development

A MODERN IRRIGATION STAFF REPORT

THE challenge that Herbert Hoover so recently flung to the west has been accepted. On October 15, in response to Hoover's plea for a broad, national program of reclamation, delegates from all the western states met in Los Angeles and founded the "Winning of the West" league, hoping that it will later become the western section of a nation-wide organization for the development of the country's resources.

Secretary Hoover, it will be recalled, was the guest of honor at a Chamber of Commerce luncheon in Los Angeles on September 8. His address dealt chiefly with the development of the nation's water resources. "Water is the greatest undeveloped resource in America today," he declared. "There are 25,000 miles of inland waterways of which less than 6,000 is in use. There are also 30,000,000 acres of land that may be reclaimed by proper water development. The undeveloped resources now going to waste each year amount to billions of dollars. . . . We must no longer think in terms of single power sites or single storage dams or single land projects, or single irrigation improvements; we must think in terms of the co-ordinated, long-view development of the national resources."

The Seed Germinates

As in the parable of the sower, some of the seed may have fallen by the wayside, some upon stony places, and some among thorns, but certain it is that some fell into good ground and sprang up and give every promise of bringing forth fruit a hundredfold.

Arthur S. Bent, president of the Los Angeles Chamber of Commerce, began immediately to consider what could be done to get action on the Secretary's suggestions. The result was an invitation sent out to the governors of all the Pacific and Rocky Mountain states, to the presidents of the various irrigation projects and development leagues, and to any others known to be actively interested in water development questions, asking their co-operation in a conference for "Winning the West," to be held in Los Angeles, October 14 and 15.

In response to this invitation some two hundred delegates assembled in Los Angeles for the purpose of discussing those matters of moment that were of more than local importance. One of the noticeable features of the meeting was the spirit of friendly co-operation prevailing.

THOMAS E. CAMPBELL
Ex-Governor of Arizona and chairman of the committee appointed by the newly-organized "Winning of the West" League to confer with Herbert Hoover on reclamation problems.

There was "no set program to be put through, and nothing to be put over," as one speaker expressed it. The meeting was an open forum in which all the delegates sought to gain information regarding each others' projects.

Ex-Governor Campbell Presides

Thomas E. Campbell, ex-governor of Arizona, was elected chairman of the meeting. He emphasized that the conference was no place for controversy—that they were come together to ascertain the wishes and views of the various states for the use and development of their mutual resources, and that their desire was to discuss what could be done for the common good of all. Mr. Campbell stressed the fact that this movement could not be local nor even western, but that the west must join with all sections of the country. "I hope," said he, "that this convention will be the birthplace of one of the big movements of the age."

With the purpose of putting before the convention the facts regarding the different projects, representatives of the various sections were asked to tell of their problems and of the plans that were being made for solution. Hervey Lindley, of Seattle, president of the Columbia Basin League, and I. E. Vining, of Portland, president of the Oregon State Chamber of Commerce, told of the Columbia Basin project.

Mr. Vining's speech was a plea for action. "Too often," he said, "meetings of this kind are merely an emotional outlet. We come here full of our subject, and when we have talked everything over and discussed all our problems, our minds are relieved and we go home feeling as satisfied as if we had accomplished something. The question is whether there will be an organization effected following this meeting that will make it possible for Oregon to co-operate in this movement. If there is to be launched a permanent organization by which the people of the west can as brothers work together for the common good instead of each for his own benefit, Oregon wants a part in it. If Columbia Basin can join with the Sacramento-San Joaquin Valley and with the Colorado River, we will meet with you in the committee rooms of Washington and plan legislation for the work to be done. Oregon wants to co-operate—will you make it possible on a working basis?"

Speaks for Imperial Valley

John L. Bacon, mayor of San Diego and president of the Boulder Dam Association, spoke of the conditions in Imperial Valley that make immediate relief necessary. The inhabitants, Mayor Bacon said, face the danger of floods part of the year and water famine the rest, while what they need is a steady flow all the time.

"The East," he said, "is not interested in irrigation because it knows nothing about the need of water. It cannot realize that there are sections of this country in which *no rain falls at all.* Yet the State of New York has more votes in the House of Representatives than has the entire section represented by the Pacific and Rocky Mountain States."

The speaker outlined briefly the Boul-

Keeping Out of the Red With *Vegetable* Crops

Thorough Understanding of the Practices and Principles of Irrigation Will Turn the Trick

By R. G. RISSER

PROPER irrigation is a most important factor in the production of high yields and superior quality in vegetable crops and it may also have an important bearing upon earliness, size of product, carrying quality, and cost of production. Yet the irrigation of such crops is not rigidly standardized and it requires the watchful attention of the producer for best results.

The ability of the grower to maintain an adequate but not an excessive supply of moisture is often plainly reflected in the success of the crop and sometimes in the manner in which the product carries to destination when shipped. On the other hand failures in growing vegetables may frequently be traced to insufficient, irregular, excessive, or improper irrigation.

Soil a Big Factor

The frequency of irrigation and the size of the head in the furrows will depend largely upon the character of the soil and the lay of the land. More frequent irrigations are required on sandy soils than upon those composed of coarser particles. On such light porous soils the most common mistake is to irrigate too infrequently and too heavily, while on heavier soils the most general error consists of supplying insufficient water to wet the soil to a fair depth or allowing too little time for it to sub between the furrows.

The moisture holding capacity of one soil may be double the capacity of one of different type and for this reason, the two soils should receive quite different treatment in irrigation.

Weather Must Be Considered

Temperature, rainfall, high winds, humidity, sunshine, etc., should be thoroughly considered in connection with irrigation plans, especially if such conditions are out of the ordinary. General climatic conditions may properly be a guide as to the customary practice of a given district while the special weather conditions of a particular season should determine the deviations from the standard practice of the locality.

Cantaloupe field in the Imperial Valley showing the initial irrigation of beds to germinate the seed. The ability of the grower to maintain an adequate but not an excessive supply of moisture is often plainly reflected in the success of the crop.

Rates of transpiration and evaporation vary, being much greater in the interior sections and during hot weather than in the coastal districts or during cooler weather. On account of the higher vapor pressure of moist air surrounding the leaves, moist air retards transpiration of the plant while lower atmospheric humidity increases the transpiration rate. The velocity of the wind is also an important factor affecting the loss of moisture.

How Evaporation Takes Place

A large proportion of the moisture which escapes from the soil passes through the plants and their foliage, and a large proportion of the water which passes up from the roots into the tissues of the plants is passed off through the leaves and other green portions into the air. The rate at which plants exhaust

Vol. II OCTOBER, 1926 No. 10

For Waterworks

THE California Section of the American Water Works Association is meeting in annual session at San Diego on Oct. 28, 29 and 30. It is the seventh annual convention of the California body, although the parent organization has been in existence nearly half a century.

When the association was young it was written into the by-laws that "the object of this association shall be the advancement of knowledge of the design, construction, operation and management of waterworks, and the encouragement by social intercourse among its members of a friendly exchange of information and experience."

It would be well-nigh impossible to measure the benefits that have accrued to mankind through the carrying out of this objective by members of the American Water Works Association. Space cannot be given here to the progress of waterworks over the last half century, but the middle-aged adult may look back over the period of the past that his memory can encompass and come to some realization of that progress without our recounting it on this page.

The idea behind a professional association such as this is in large measure responsible for this progress. The American Water Works Association has learned from long experience that developments cannot come from the unco-ordinated efforts of individuals, no matter how great their abilities. Like other societies in the public utility field, it is looking to strong active committees to co-operate on waterworks developments and on solutions to problems that beset the engineer. The organization has the utmost flexibility and is able to accomplish with a minimum of effort and expense, and without duplication of work, all the results attainable through co-operation.

A GLANCE at the program for the California Section's convention, printed elsewhere in this magazine, will serve to give some idea of the immense practical value of the association's work. Members from all parts of the state gather at these conventions and exchange experiences and information to their mutual benefit. This year, happily, invitations were extended to members of the profession in other Pacific Coast states to attend the convention, an innovation that should become permanent. With the participation of waterworks engineers from other coast states in the California conventions it is not difficult to conceive of the possible extension of membership in the section to embrace the entire Pacific Coast.

WESTERN WATERWORKS, the new supplement to MODERN IRRIGATION which begins on page 32, is dedicated to the belief that an intelligently directed press can aid immeasurably in the dissemination of these ideas and experiences of the waterworks men. For the time being WESTERN WATERWORKS will be a magazine within a magazine, but will always have as its primary concern all matters having to do with problems of water conservation and development (as they relate especially to domestic and industrial supply) that are so peculiar to the west. It will be a clearing house of current information on western waterworks. If it can attain some success in this direction it will consider its existence well worth while.

The Sensible View

HERBERT HOOVER, whose broad vision, coupled with an engineering training, enables him to encompass huge undertakings in their entirety without getting out of focus, has, in the course of a recent trip through the west, given voice to thoughts about reclamation and irrigation that should be shared by every thinking person concerned with this country's future development.

Water development in the United States, Hoover said before a Chamber of Commerce luncheon in Los Angeles, must not be considered a series of sectional propositions, but as one comprehensive national undertaking, inasmuch as the far-reaching effects of such development must, necessarily, be national in scope. There are many ramifications to the problem, but the task can be performed if the public can be made to visualize it as a national enterprise.

Such a public viewpoint as Hoover hopes for, while it seems, in theory, to present no stumbling block, is not quite so easy to effect in practice. The Colorado development, for instance, which ultimately will reclaim between 5,000,000

See Page 33 for First Issue of "Western Waterworks"

POINT *Of* VIEW

and 6,000,000 acres of land, is the particular concern of the localities that will benefit directly from that development; but it is difficult to get anyone in the northwest greatly interested in it, just as it is no easy matter to arouse the interest of people in the southwest in projects that affect, more directly, the development of the northwest. And to make the problem yet more complex, the different communities involved in any large development, such as the Colorado River projects, can envision little else but their own interests and they generally fail to understand—or care to understand—the interests of their more remote neighbors.

The inevitable result is that the big projects which mean so much to the development of all the west, and to the United States at large, become snagged on petty sectional politics and in long drawn-out litigations. As Hoover puts it, "Politics and litigation create much feeling over water development, but not much development."

The sooner the Hoover attitude becomes that of every individual concerned, directly or indirectly, in the development of the nation's water resources, the sooner will that development be ushered forward on a scale that will insure not alone the prosperity of a particular locality, or of a certain state or group of states, but the nation as an economic whole. We shall stand socially, politically, economically, as our country does. There can be no mistake about that.

The Short-Sighted View

THE fact that Secretary Hoover has so recently been in the west and given voice again to his reclamation theories makes the jolt all the more severe when one picks up the October issue of *Farm and Fireside*, a widely read farm journal, and reads on the very first page that "Reclamation Has Failed."

The editor of this publication states that the "reclamation policy of the United States has been premature." "The nation has no need for new farm lands," he declares. "The government should complete its obligations to the settlers on established projects. The beginning of any new works before the nation requires more food supplies must not be permitted."

This expression accompanies an article in the magazine by Arthur P. Chew, of the Division of Information, Department of Agriculture, who says that the governernment's reclamation policy is a failure because reclamation isn't needed.

The view is not new, of course. It has been expressed again and again by disgruntled settlers, individually, and farm organizations of one kind and another, collectively. But appearing in black headlines in a magazine of the repute of *Farm and Fireside*, the statement that "reclamation has failed" can do much more harm than good. For, as a matter of fact, reclamation *has not* failed.

It is the easiest thing in the world for the swivel chair thinker to jump to the conclusion that additional farm land is not needed when he reads of failures on reclaimed lands in the west. It is the kindest view, perhaps. It spares the feelings of the individual settler, who has been coddled by the government from the time he set foot on his homestead and isn't used to criticism; and it spares the management of the projects that have shown up in the red. Uncle Sam has been criticized by experts. Blame him.

SOMEONE has been unkind enough to say that failures on reclamation projects have been due to the weakness of the settler who, unable to make a living at anything else, has turned to farming on government land because "it doesn't cost anything." In other words, the thought is that life is a survival of the fittest, and those who settle on federal projects just aren't fit.

We cannot subscribe to a view which not only does an injustice to the pioneers on reclamation projects, but is, as well, an implied slander on those earlier pioneers who first crossed the hot sands to initiate the settlement of the west. But we do feel that the failure has not been with the idea of reclamation, but rather with the individuals concerned with the settlement of these projects.

It is too much to expect to make a successful dry land farmer over night out of one who has lived all his life in a humid section or who never had any farming experience before taking up a homestead. But it is not too much to expect that the active management of government projects be blessed with a reasonable amount of intelligence and an understanding of the dry farmers' peculiar problems that would assure the latter of practical co-operation and advice and not hot air and indulgence.

THE view that "the beginning of any new reclamation works before the nation requires more food supplies must not be permitted," is entirely uneconomic, the answer to which is best expressed in Herbert Hoover's own words:

"I would," he declares, "be opposed to such development myself were it possible to bring it about in a few days. But it must be remembered that these projects take time. Even if the program I have outlined could be started tomorrow it would be at least fifteen years before it would affect agriculture. At this moment we could not make economic use of the whole of this power or all this land, or all these inland waterways—but we will need the whole of it within half a generation."

The opposition to reclamation and waterway development from the agriculturists on the one hand, who fear overproduction, and from the railroads on the other, who fear the competition of water shipping, may be a natural reaction, but it reflects a distressing lack of foresight. Those whose vision can hardly encompass the future beyond the setting of today's sun should bear in mind that careful estimates place the population increase of this country in the next quarter of a century at 40,000,000. Certainly efforts must be made during the next ten years to stimulate agricultural production to provide food for this increase.

See Page 33 for First Issue of "Western Waterworks" ☛

Two Rivers' Epic Problem

(*Continued from Page 17*)

fits to be derived from its exercise will extend only so far as the water users' mutual agreements permit it.

Mutual Settlement Works

In the 1924 agreement adopted by the Permanent Committee and signed by the water users, provision to meet the immediate season's crisis was made in specifying the duties of and delegating certain authority to the Water Supervisor as respecting conservation measures and waste prevention. Looking more to the future, however, and to the ultimate solution of the problems it was specified that the Water Supervisor should commence the engineering investigation, the collection and recording of the hydrographic facts, most essential to an intelligent and permanent settlement in water difficulties of this nature.

The success attendant upon the 1924 conservation efforts was most noteworthy. The water users acceded readily to requested measures and accomplished much in the way of waste prevention and a careful use of water. After June there was not sufficient flow in the Sacramento River above Sacramento to maintain navigation, and, taking a lenient attitude, no attempt was made on the part of the U. S. War Department officers, charged with the maintenance of navigation, arbitrarily to enforce the superior legal rights of the federal government in this respect by enjoining water diversions. This confined the problem chiefly to the irrigationists and the pressing necessity of keeping fresh water flowing to the delta to save great areas of valuable crops there from the salt water encroachment.

Through appeals made to the up-river water users by delta owners, members of the Permanent Committee and others at a meeting of water users called at Colusa by the committee at the time of the crisis in the last of July, the river flow was decidedly increased, and the salinity actually driven back many miles in the Sacramento Delta. The estimated saving to the delta resultant therefrom was decidedly worth while.

The engineering investigation commenced in 1924 and continued to date has included the following: measurements and records of all diversions of water from the Sacramento, Feather, Yuba, American and Lower San Joaquin Rivers within the valley floor and above the delta; stream flow measurements throughout the territory, partially in co-operation with the Water Resources Branch, U. S. Geological Survey; measurement and record of waters returned both to the Sacramento and San Joaquin Rivers; intensive studies of the duty of water on peat and sedimentary lands in the delta region in co-operation with the U. S. Department of Agriculture, Division of Agricultural Engineering and the University of California Agricultural Experiment Station; yearly census of irrigated areas and crops under all diversions recorded and throughout the delta; and investigation and study of the advance and retreat of salinity in the delta channels.

Pump Diversions Prevail

With the exception of four large gravity systems, all of the diversions recorded are by pumping. The diversion records obtained in 1925 included 194 on the Sacramento River above Sacramento, 31 on the Feather River, 5 on the Yuba, 28 on the American and 32 on San Joaquin River Channels diverting to the delta uplands. The Sacramento River records show that there was a draft above Sacramento amounting to 953,000 acre-feet in 1924 and 842,000 acre-feet in 1925. A considerable portion of this draft is returned to the river, however, and the return water is available for use in the lower river and delta. The flow of all channels carrying this return water to the river is measured and recorded. The 1924 measurements indicated a return above Sacramento for the four months, June to September, equal to 33 per cent of the draft. The 1925 figures showed a corresponding return for July to October equal to 40 per cent. Each season three complete series of return water measurements have been made on the San Joaquin River and tributaries.

Within the delta it is not feasible nor practical to measure and record the countless number of diversions by siphon, gravity and pumping as well as the concurrent drainage pumping, which is considerable. Here the consumptive use of water must be estimated by applying the best "duty of water" figures obtainable to the various areas irrigated and cropped as shown by the yearly census. The proper determination of the "duty of water" data for peat and sedimentary soils, for different crops, etc., is the somewhat difficult task here involved. The detailed and intensive investigations along this line to date have been conducted on Medford and King Islands near Stockton for the peat soils, and on Reclamation District Number 999 near Sacramento for the sedimentary soils. This work has required the installation and use of many different water measuring devices and calls for a considerable amount of ingenuity and skill upon the part of the engineers in getting reliable results.

The encroachment into the delta channels of salt water from San Francisco Bay when in dry seasons there is insufficient flow of fresh water in the rivers to hold it back is a serious problem. Each season investigations have been carried on to determine, by means of testing water samples taken at two or four day intervals at stations throughout the delta, the movements and behavior of the salinity. Chief of the objective in this work is the determination of the relation existing between the advance and retreat of the salt at various delta points and the discharge of the rivers to the delta. With records of the Sacramento River flow at Sacramento and the San Joaquin River flow near Vernalis available since 1924, the work to date has demonstrated this relation within somewhat wide limits. Should reservoir storage become available at some future time as a means of controlling the salinity, the value of a knowledge of the required discharge and proper time for storage release is obvious. As an aid to the delta irrigators in avoiding the use of water with too high a salt content, bulletins showing the results of the tests are mailed throughout the delta once a week or oftener during critical periods.

Approaching Danger Mark

In the present season, with the bay drainage run-off estimated at about 50 per cent of normal, the situation has closely approached that of 1924, principally due to this year's much greater rice acreage, about 150,000 acres. The 1924 acreage was about 100,000. A greater late Spring run-off helped considerably, however, and caused the salinity encroachment in the delta to be from 30 to 40 days later than in 1924. In early August, critical stages had been reached in the vicinity of Colusa and the salinity was advancing rapidly into the delta. Navigation above Sacramento became precarious in early July and at the instance of the U. S. War Department an appeal was made for conservation to assist in its maintenance. Excellent response from the water users was received and all that could be accomplished through waste prevention and voluntary diversion reductions was done. With river levels continuing to drop, however, and navigation suspended, it is evident, as this is written, that navigation could now be maintained only through the actual elimination of a considerable irrigated area.

At the close of the 1924 season's work which, it should be noted, was almost entirely financed by the water users

A dragline with features a dragline should have

Talk to contractors who have put Northwests on jobs where other machines were working. Many of them will tell you that Northwest draglines increase their output from 15 to 30 yards hourly. That is what comes with Northwest features, features a dragline should have.

Full traction while turning as well as while going straight ahead; ample clearance beneath the base casting, no low hung gears to catch on high centers; fair lead on the machine, not on the boom, bringing full value of the boom length and assuring the maximum cut; the "feather-touch" clutch control that takes the backache out of operation and assures speed; simplicity of design, no air compressors, tangled mess of pipe and gearing and easy convertibility that brings maximum versatility —these are the things that you need to meet competition in bidding.

Confer with us on your next job, our men will be glad to help you.

THE HYDRAULIC DIGEST

A Monthly Bulletin Board of Brief Facts and Events from Far and Near

Stony Gorge Dam Contracted

The Amburson Construction Co. of New York has been awarded the contract for the construction of the Stony Gorge Dam near Elk Creek, California. The Orland project water supply will be doubled by the completion of the dam.

McKay Dam Is Almost Ready

At McKay Dam, Umatilla project, Oregon, all concreting on the face of the dam has been completed, says a report from the bureau of reclamation, and the spillway gates and lifting devices have been installed. This dam will store 75,000 acre feet of water.

Redmond Looks to the Future

Redmond, Washington, has bought one hundred and sixty acres of land for future water development, according to the report made by the town council. The land purchased contains a natural flow of springs. Tests made of the water show it to be of excellent quality. They have been busy with the repair of water mains in the present system, and has laid considerable new pipe.

Turns Projects Over to Users

The bureau of reclamation has turned over to the water users the operation and maintenance of a number of federal irrigation projects and divisions, says a recent announcement from the Department of the Interior. The projects affected are located in Idaho and include several divisions of the Boise project, the King Hill project and the south side pumping division of the Minidoka project.

Ask Repair of System

The West Side Water Users Association, Lakeview, Oregon, has sent in a complaint to the officers of the Goose Lake Irrigation System, stating that the system was not in good repair and that it would not supply the water from the reservoirs without great waste. The irrigation company, it is reported, has assured the association that repairs will be made so that water can be distributed properly during the next irrigation season.

El Paso Boosts Water Charge

Due to $40.000 worth of flood prevention and corrective work done last year by the reclamation service, and to $17,000 suspended revenues, the minimum per acre charge for water in the El Paso, Texas, irrigation district will be increased 50 cents, making the minimum $2.60. There are 59,500 acres in the irrigation district now subject to repayment to the government of storage, irrigation and drainage costs, according to the statement recently sent out by the district.

Flood Control Office Closed

The flood control office of the California Department of Public Works was closed on October 1 because of lack of funds for its maintenance. State Engineer Paul Bailey reports that in the new budget for the department he is asking for an appropriation for the maintenance of the office, but he does not think it advisable to ask for an emergency appropriation for the conduct of the office until such time as the budget fund might become operative.

Power Plant for Cane Irrigation

Electric power is to be used for irrigation purposes in Honolulu, according to a report from the Chamber of Commerce of that city. The stockholders of the Pioneer Mill Co., in Honolulu, have voted to issue bonds for $1,500,000. A power plant with a 3,000-kilowatt steam turbine, which will supply power to operate high-lift pumps, will be built. Double the supply of irrigation water is needed for new varieties of cane which yield twice as much sugar as ordinary cane.

Saratoga Outlook Is Improved

The outlook for accomplishment of the Saratoga irrigation project (Wyoming) is more encouraging, according to a report from state engineer Frank C. Emerson on his return from an inspection of the project in company with representatives of the federal government. The project contemplates the reclamation of 38,000 acres in southern Carbon county, with water from the North Platte river.

Tule Lake Begins Overflow

Reports from Klamath Falls, Oregon, state that Tule Lake, on the Oregon-California boundary line, is undergoing its annual rise earlier than usual this year and has inundated nearly 200 hundred acres of wheat land. Due to an earlier harvest season the damage to crops will not be as great as that of last year. The reclamation service established a border around the lake for leased land, and those who go below this deadline to plant do so at their own risk of inundation.

Work OK's. Okanogan Contract

Hubert Work, secretary of the interior, has approved the government's proposed contract with the Okanogan irrigation district in Washington for the construction of a pumping plant to relieve a water shortage of several years duration, according to a report by B. E. Stoutemyer, district counsel for the United States bureau of reclamation. Residents of the district must approve the contract by vote before it becomes valid. If the contract is accepted by the district, the government will expend not to exceed $300,000 toward the construction of a plant to pump water from the Okanogan river. The district will repay the money in 30 annual installments without interest.

Bids Asked for Coolidge Dam

Bids for construction work on the Coolidge dam on the San Carlos irrigation project, Arizona, will be received at the Los Angeles office of the Indian Irrigation Service, according to the advertisements issued by the Interior Department on October 11.

The Coolidge dam is the main irrigation structure on the San Carlos project. The project will embrace approximately 100,000 acres of irrigable land in the Florence-Casa Grande Valley in Arizona, 50,000 acres of which belong to the Pima Indians of the Gila River Indian Reservation, the remainder comprising lands in public and private ownership. Construction of the dam was authorized by Congress at a cost not exceeding $5,500,000.

See Page 33 for First Issue of "Western Waterworks"

Two Rivers' Epic Problem

(*Continued from Page 22*)

themselves to the extent of some $17,000, a second River Problems Conference was called. This was held at Sacramento on December 12, 1924. The season's work was reviewed and the Permanent Committee presented its report and recommendations. This conference voted to continue the committee and recommended that the state legislature be asked to appropriate funds to continue the work of the Water Supervisor. This the legislature did and the appropriation made insures the continuation of the work until July 1, 1927.

Season's Work Surveyed

With the drawing to a close of the third season's operation under the methods and plans initiated by the 1924 Water Users Agreement, an outcome of the First River Problems Conference, an opportunity is presented to review such progress as may have been made in dealing with Sacramento-San Joaquin water problems.

Of prime importance, the efforts to date have come as a result of, and have strengthened, the spirit of co-operation, welding together the various diverse interests so as to make the best of the situation and avoid expensive and extended litigation. Following the Antioch Suit, one of much greater proportions was filed. The loss in time, money and retarded development which would be entailed by the trial of this suit is fearful to contemplate. But with the action of the River Problems Conference, the Permanent Committee and the State, this suit has not been pressed.

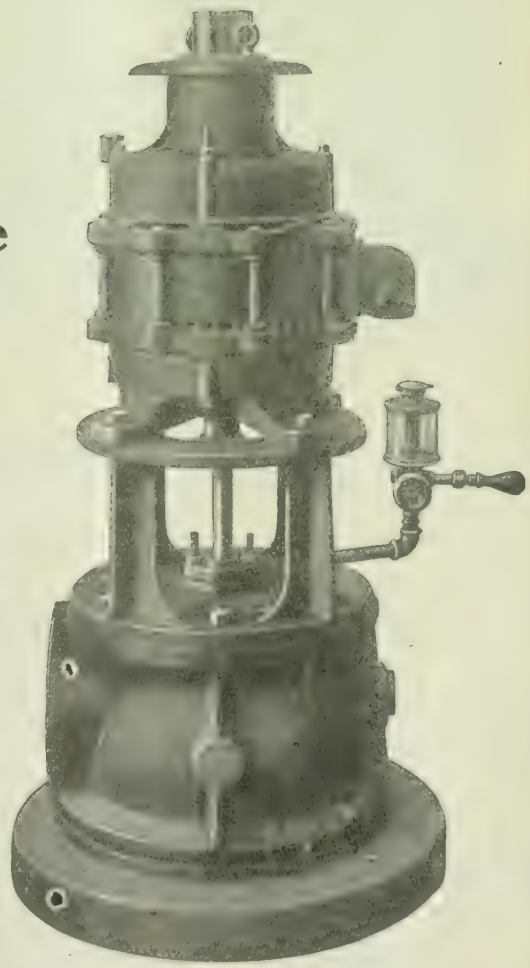
In the Permanent Committee and River Problems Conference there has been created a most fortunate medium for dealing with the problems involved; and at present, the committee, influential and representative, stands ready as the proper body to forward all constructive plans for bettering the river conditions.

In the collection of the three years' records of the use of water and other fundamental physical facts and data, a necessary and important step has been taken leading to ultimate adjudication, adjustment, mutual agreement or whatever will be consummated as a basis for water distribution.

The procedure to date has been to make the best of the situation through conservation. This includes Water Supervision or Water Master Service which is essentially a conservation feature. Until such time as additional water supplies are made available through storage or otherwise this will undoubtedly continue to be the best and only reasonable procedure.

Layne & Bowler
Turbine Centrifugal Pumps

—backed by 42 years of experience



More than 8000 pumps in successful operation testify to the reliability of Layne & Bowler Pumps. They have gained an enviable reputation for doing everything we represent them to do. Incorporate many superior improvements backed by 42 years experience.

The cost of Layne & Bowler Pumps is no higher. We have prepared an interesting catalog giving full information. Ask for a copy.

RECLAMATION

Unified Program of *Orderly Reclamation* Is Keynote of Oregon Reclamation Congress

A WARNING against overemphasizing production in devising farm aid, with a resultant neglect of marketing, was sounded by Dr. Richard T. Ely in addressing the 16th Oregon irrigation congress, held at Hood River, Oregon, Oct. 14, 15 and 16. Dr. Ely, who spoke on "The Utilization of Land," is a professor of economics at Northwestern University and is in charge of the national bureau of land economics and public utilities.

Dr. Ely declared that the ills of the farmer have come from an over-abundance of cultivated land. Quoting Adam Smith, the noted Scotch economist, Dr. Ely said that the farmers of America today are the living examples of that axiom that those engaged in any line of activity which has obtained special favors, are certain to find their services receiving low pay. He cited how farmers throughout the land have been receiving aid from the federal and state governments, railways and numerous other sources.

Sees No Early Famine

Dr. Ely declared that agricultural colleges have directed their curricula disproportionately toward aiding farmers in ways and methods of bringing about production instead of providing studies that would result in farmers' profits.

He minimized the forecasts of those economists who foresee an early famine of foodstuffs. Dr. Ely cited the great reduction of animal population as a result of the introduction of motor propelled vehicles, and the release of land formerly utilized for feeding such stock, for production of foodstuffs for human consumption. He declared that at present the products of 61,000,000 American acres are being exported. However, said the speaker, investigation revealed that numerous foreign countries, to which America has been exporting were developing export surpluses of their own.

Dr. Ely expressed the belief that predictions of a population of 200,000,000 in America by 1959 are far from correct. His forecast is that the nation will have less than 150,000,000 and that the worries of a lack of food will not be apparent for several generations.

Urges Land Reclassification

As a remedy for the present disproportionate status of agriculture, Dr. Ely suggested a reclassification of lands and that all be put to those particular uses for which they are fitted. The state of Michigan, he said, has inaugurated such a system with the result that 6,000,000 acres of land have been purchased for reforestation. He declared that the policy of settling much of the cut-over or logged-off land of the country is detrimental to best interest of agriculture, but that state and nation should co-operate on a broad scale in a scheme of reforestation. Vaster tracts of land the speaker declared, should be utilized for recreational purposes.

Dr. Ely during the course of his address praised both the University of Oregon and Oregon Agricultural college for their efforts in aiding in the solution of agricultural and economic problems. He urged that the institutions be given larger appropriations for research work.

"Where you are now providing $1," he said, "you should be making available $20."

President Makes Address

Other speakers and topics on the first day of the session were: James T. Jardine, director of the Oregon experiment station, "The Use and Misuse of Water," and "Land Settlement," W. G. Ide, secretary of the Oregon state Chamber of Commerce.

President Wilfred Allen in his annual address, said: "While we have been most concerned as regards irrigation projects organized under state law with the rehabilitation and settlement of those already constructed, there is a general rejoicing that Oregon will get some measure of justice from the federal program. The announcement of approval of the great Owyhee project means that nearly $18,000,000 of federal money will come into Oregon to reclaim 124,000 acres of fertile soil. The federal authorities have been slow to recognize the demands of this state, and let us hope that a more liberal policy may now be maintained toward Oregon. The national government is always slow in development work of this character and by the time the projects can be ready for settlement there will be a crying need for the production of the area. Settlement will then come as a matter of course."

The address of welcome was delivered by Mayor Bennett.

The congress, it was declared, has the best representation from irrigated areas in its history, the registration included:

Mr. and Mrs. Z. O. Powell of Prineville;D, J. McLellan, Tumalo; E. T. Newby and O. Arnspiger, Talent; Ralph Cowgill, F. C. Dillard and John H. Carkin, Medford; Henry J. Kennard, Vale; Gail A. Hathaway, Thomas B. Kay, Fred H. Coshow, Salem; E. M. Wright, Bend; W. G. Ide, Portland; R. H. Dearmond, Warm Springs; Percy Purvis, Vale; C. C. Cignoux, Portland; Leslie Butler, George E. Goodwin, George R. Wilbur, J. H. Hazlett, Roy Hays, C. M. Hurlburt, E. E. Lage, Nels C. Hagen and John Plog, Hood River; R. H. Townsend, Portland; Walter E. Meacham, Baker; L. K. Cramb, Bend; H. A. Walthers, Medford; Marshall N. Dana, Portland; N. G. Wallace, Prineville; Walter A. Holt, Pendleton; George N. Angell, Portland; W. L. Powers, Corvallis; George Huntington Curry, La Grande; John S. Beal, Portland; P. Nelson, Redmond; W. A. Steward, Baker; E. T. Slayton, T. E. Thompson and W. B. Tucker, Prineville; H. R. Christensen, West Side, Lake county; Lester E. Elder, Summer Lake; P. G. Fortner, Lakeview; E. C. van Patten, Bruce R. Kester and W. J. Pinney, Ontario; E. M. Blodgett, Nyssa; C. H. Oxman, Vale; W. L. Shovell, Ontario; Willford Allen,

Grants Pass; Delbert Utter, Portland; and L. R. Breithaupt, Corvallis.

Refunding Attempt Seen

State Treasurer Kay, addressing the congress, predicted a strong effort will be made to induce the next legislature to pass a measure authorizing the state to refund outstanding irrigation bonds amounting to $12,000,000 or $13,000,000. Such a measure, he prophesied, would not receive the necessary approval of a popular vote. He said he would strongly oppose such a move himself, and intimated many leading business men throughout the state had expressed similar sentiment.

As a substitute plan, Mr. Kay suggested the appointment of a commission to make a survey to determine actual value of the outstanding bonds, the bondholders placing the securities in escrow with the state until such valuation had been arrived at, when the state would reimburse the bondholders on the basis recommended by the commission.

Under this plan, Mr. Kay pointed out, the bondholders would share equitably in the losses suffered by the settlers. He said he believed the plan, if authorized by the legislature, would carry at the polls, the vote of the people being necessary under the 6 per cent limitation law.

Need for Industrial Growth

While favoring strong support of existing projects, Mr. Kay said he disapproved of launching new irrigation projects in Oregon for some time to come, declaring "more lands are available now than can be settled."

"Forget all plans for horticultural and agricultural expansion for the present," he urged, "and concentrate effort on encouraging industrial expansion. Only in this way can we create a greater consuming public to take care of the large surplus of farm productions which is keeping prices down and cutting into the profits of the producer."

Mr. Kay said he was not speaking officially in his capacity as state treasurer and ex-officio member of the land board, but chiefly to guide members of the congress in making suggestions for legislative improvements when the legislative committee meets.

Another View

Legislation alone will never cure the troubles of irrigation, Paul V. Maris, director of the extension service of Oregon Agricultural college, declared at the banquet of the congress. Much more, he said, is to be accomplished through scientific and intelligent use of the land. He cited the fruit industry of the Hood River and Rogue River valleys and the dairy industry of Tillamook county as examples of intelligent intensive farming.

Water
at lowest cost

Inspect any F-M equipped pumping plant and you will not find it difficult to account for the low cost per gallon of water pumped.

You will trace the higher efficiency in many cases to the use of Fairbanks-Morse "unit-built" equipment—pump and motor combinations, for example, in which both pumping and power ends are designed and built by one manufacturer.

You will find another contributing factor in the use of F-M Ball-Bearing Motors —either horizontal or vertical shaft— which combine the reliability of F-M full-measure design with the many advantages and the minimum attendance requirements of ball-bearing construction.

The Brownstone Mutual Water Co. plant, illustrated above, is typical of many F-M equipped plants enjoying low pumping costs. F-M engineers will gladly help you plan equally efficient pumping layouts.

Mr. Maris' department of the agricultural college, he told the banqueters, conducted during the last year an economic survey of the Umatilla reclamation project which resulted in a reclassification of the lands and brought the settlers on that project to the point of success. He invited the other irrigation districts represented at the congress to avail themselves of the various services of the college.

L. P. Jessup, drainage engineer for the United States department of agriculture, said in an address that the full significance of drainage had not been realized in the adaptation of waste lands and declared that full success would be realized only through joint use of drainage and irrigation.

More About Legislation

John Carkin of Medford, voiced the hope that from this congress would result workable remedial legislation for presentation at the next session of the legislature.

"Even though we had ready to place before this organization laws, fully drafted—and we haven't—I would recommend that they be withheld until after the November election," said Percy Cupper, ex-state engineer and member of the Oregon Reclamation congress. "We have kept Oregon irrigation out of politics in the past and we do not wish to throw it into politics now."

Walter E. Meacham of Baker expressed disapproval of the attitude of the committee, declaring that Mr. Cupper and his associates should have ready for presentation some actual definite recommendations on which the delegates to the congress might act in ratification or rejection.

Mr. Cupper said that his committee had reached the conclusion that the state should not be held responsible for the refunding of the irrigation bonds; that no moral responsibility attached.

Mr. Cupper proposed the appointment of some responsible commission with enlarged powers, the chief function of which would be to obtain responsibility of individuals in irrigated districts. He declared that legislation alone would not solve the irrigation problem, but that the settlers, the state and the bondholders must co-operate in an acceptance of losses.

Rhea Luper Speaks

Rhea Luper, state engineer, cited that ten of the state irrigation projects were in distress. The total bonded indebtedness of these reaches $6,014,000. Four of the ten districts in trouble are in permanent default. In some cases, he said, the taxes exceed the rental value of the land.

Mr. Luper recommended that Oregon irrigation laws be so revised that provisions similar to the Bancoft bonding act, under which the improvement of city streets in the state is conducted, be applied in such wise that blanket mortgages on systems be eliminated. Under such a system the settler who pays his assessments would be eliminated from assumption of the responsibility of other land owners who allow assessments to grow delinquent.

Imperial Profits by Water Sales

That American ranchers in Imperial Valley derived a substantial profit from the sale of water to farmers on the Mexican side of the boundary, is disclosed by the report of the Imperial Irrigation District engineer for the past year.

The report shows that the gross income from the sale of water to users in Mexican Imperial Valley was $630,258.64.

This sum not only paid for all canal operating costs in Mexico, but covered the administration expense for the headquarters office on the American side of the line, amounting to $96,693.39, canal-maintenance charges of $134,897.30, Boulder dam legislative expense amounting to $26,310.66, and all costs in connection with the diversion of water at the heading, and left a net profit to the district of $84,371.84.

The figures show that if Mexican users were charged only with their prorata of the total expense of the district the profit to the American owners of the system would be in excess of $400,000.

If it were not for the income from the sale of water to Mexican lands, the tax rate in American Imperial Valley would be approximately 50 per cent higher than it is, according to the assertion of local engineers.

Studies Irrigation Projects

A committee of three, according to an announcement made by the Bureau of Reclamation, has begun an inspection of representative irrigation projects in the West in connection with a study in progress into the operation and maintenance methods on irrigation projects. The inspection trip was begun September 22 and is expected to be completed by December 5, the bureau said. The purpose of the study is to determine what, if any, improvements can be made in the Federal reclamation service.

The committee is composed of Porter J. Preston, representing the Bureau of Reclamation; L. M. Holt, representing the Bureau of Indian Affairs; and R. S. Carberry, representing private irrigation projects. Headquarters have been es-

See Page 33 for First Issue of "Western Waterworks"

tablished at Denver, Colo., where preliminary surveys have been made.

The projects to be inspected are: Uncompahgre project, in Colorado; Blackfoot and Ft. Hall Indian projects, in Idaho and Montana, respectively; a Yakima project, in Washington; Newlands project, in Nevada; Turlock project, a private undertaking in California; Yuma project, in Arizona-California; and Rio Grande project in Texas.

Clear Away 30 Miles of Logs

Opening of the Colorado River to its normal flow by clearing it of the great raft of logs which extended from its mouth up-stream for thirty miles is regarded as one of the most remarkable feats of its kind ever known in contracting circles, according to a report from Matagorda, Texas. For more than thirty years the river was blocked by this almost solid mass of timber, and with each flood the raft was extended up the river farther and farther.

The obstruction caused disastrous overflows of an enormous area in time of flood. In 1922 an overflow occurred which caused losses aggregating more than $3,000,000 to farmers and other interests.

The task was begun by dynamiting the raft at the mouth of the river and slowly progressed up-stream until the channel was opened a few days ago. For the first time in thirty years the river was opened and it is possible for small boats to traverse its entire lower course.

Besides obviating the dangers of overflow of a large area of rich land and the flooding of several towns, the removal of the raft will reclaim more than 100,000 acres of farm land that was under water by reason of the great log dam. This land will be planted to cotton, sugar cane, and other products, it is stated.

Studies Routes for Canal

A consulting board of United States reclamation engineers met in Ellensburg, Washington, on October 20, to recommend as to which of several alternate routes would be adopted for the main High Line canal for 12 miles above the Yakima river siphon. The first four miles of the main canal from Easton down are now under construction by the General Construction Co. of Spokane. Plans for the next ten miles have been completed and it is expected that bids for this section will be opened toward the end of November. For the last twelve miles of the main canal, the section above the siphon and the most difficult on the entire canal, plans will be completed and bids called for before winter breaks up so that work may be begun in the early spring.

HYDRAULIC ENGINEERING

Dealing with the Practical Problems of the Operating and the Consulting Engineer

Interior Department Describes Engineering Aspects of Vale Irrigation Project

THE Vale Irrigation project, in the state of Oregon, is one of the six for which Congress, at its sixty-ninth session, made appropriations, and which, when completed, will cost approximately $54,000,000. The Department of the Interior has just made public a statement describing the proposed plan of construction of this project, as proposed by R. F. Walter, chief engineer of the bureau of reclamation.

The proposed Vale project contemplates the irrigation of 28,350 acres of bench and valley land lying mainly along the north side of the Malheur River in eastern Oregon, centering around the towns of Harper and Vale, above the present Warmsprings project.

The irrigation plan for this project is closely related to that of the Warmsprings irrigation district, which has constructed a reservoir on the Malheur River about 60 miles west of Vale with a surplus capacity over that required for the district lands. One-half of the present capacity of 170,000 acre-feet is to be purchased for the Vale project at a cost of $8 per acre-foot.

Raise Water Level

The installation of gates on the crest of the dam, which was provided for in the original plan, will permit the maximum water surface of the reservoir to be raised four feet and provide an additional 20,000 acre-feet of storage. This additional cost and capacity will be apportioned equally to each district.

Water released from the reservoir will flow in the channel of the Malheur River to a point about one mile west of Namorf. At this point a simple diversion weir, 12 feet high and 150 feet long, resting on rock, will be constructed.

This weir will require 4,000 cubic yards of excavation and 300 cubic yards of concrete. The canal head gates will be set at right angles to the crest of the weir at the left or north abutment.

From this point to the upper end of Harper Valley, a distance of about six miles, the main canal will have a capacity of 646 second-feet and construction will be difficult owing to the presence of rock, steep cross slopes, and conflict with the Ontario-Burns branch of the O. S. L. Railroad, which crosses the Malheur River immediately below the proposed point of diversion.

THE contract approved by the Department of the Interior provides for the expenditure by the United States of not to exceed $4,500,000 for (a) the purchase of a one-half interest in Warmsprings Reservoir from the Warmsprings irrigation district, (b) the construction of a diversion dam in the Malheur River in Sec. 6, T. 21 S., R. 41 E., Willamette meridian, (c) extending therefrom a canal system consisting of a main canal and branch canals and structures, and (d) the necessary drainage works, as found by the Secretary.

Upon the completion or termination of the construction program the Secretary of the Interior is to furnish the district a statement of the total amount of the construction costs payable by the district to the United States under the contract. The district is to pay the construction cost as stated by the Secretary.

If water becomes available for any part of the project before the completion or termination of the construction program as a whole, the Secretary is to give notice to the district to that effect, describing the legal subdivisions of land for which water is available, and giving the tentative per irrigable acre construction charge payable by the district on behalf of such completed portion of the project.

The canal will be carried under the railroad by means of a concrete culvert. For approximately one mile the canal will follow the north side of the river and will then be carried to the south side by means of a flume 800 feet long, of which 100 feet would be on a steel bridge.

For the next four miles the canal parallels the river on the south side to a point which is favorable for a siphon location, and where conflict with the railroad does not occur. At this point the canal is to be returned to the north side by means of a concrete siphon 1,015 feet long.

Engineering Problem

Owing to the difficult territory traversed by the canal a large amount of steel and concrete bench flume will be required. In this six-mile canyon section immediately below the point of diversion the aggregate length of steel and concrete flumes and siphons will be 14,000 feet.

After leaving the canyon the canal supplies water for the Harper tract. This is an area of 3,735 acres of bench and bottom land north of the Malheur River contiguous to the town of Harper.

Across the river from the lower end of the Harper tract is an area of 675 acres known as Little Valley. Water for this area is to be carried across the river by means of a second siphon. This is the only area south of the Malheur River for which works will be constructed.

Separating the Harper tract from the Vale Valley is a canyon about 6 miles in length. The conditions here are very similar to those encountered in the first six miles below the point of the diversion. Between the Harper and Vale Valleys the aggregate length of flumes and siphons will be 13,000 feet, in addition to which there is required 572 feet of concrete-lined tunnel 11 feet in diameter.

Vale Valley is reached at the end of this canyon, and the main canal thereafter has but one structure of importance, namely a 70-inch reinforced concrete siphon 6,200 feet long across Bully Creek.

Drainage is expected to be required on only a small part of the total area, principally in the Willow and Bully Creek bottoms.

The surplus storage capacity of the

See Page 33 for First Issue of "Western Waterworks"

THESE power heads are totally enclosed, self-lubricating, with gears operating immersed in a bath of oil, making a very quiet and smooth running power head.

The massive main frame serves as a complete housing and a rigid support for all working parts. The main gear is driven through a pinion which actuates a crank shaft, which in turn actuates an all-steel walking beam which operates the crosshead. This power head may be slid back upon its base, which permits the removal of the rods and drop pipe without tearing down the installation or disturbing pipe connections.

While illustration shows motor drive, these power heads can also be successfully operated with a gasoline engine.

They are made in both 18-in. and 24-in. stroke

These heads are more fully described in bulletins, sent on request.

WESTERN Waterworks

Supplement to Modern Irrigation

Of Interest Expressly to Waterworks Executives, Contractors, and Municipal Engineers

California Section, A. W. W. A., Faces South for Its Seventh Annual Convention

MEMBERS of the California Section of the Water Works Association and others interested in the annual convention at San Diego, Calif., Oct. 28, 29, and 30, are, as this is written, packing their grips for the journey southward. The meeting will, without a doubt, be the largest of all the annual conventions that have been held by the state body.

Not only will the three-day session call to San Diego a representative gathering from the water works field in California, but there is a strong probability that Washington, Oregon, Arizona, and perhaps one or two other Pacific Coast states will be represented through the attendance of water works authorities from these sections. Special invitations have been sent out to water works officials in several of the Pacific Coast states outside California, and it looks as though Arizona will probably be especially well represented.

The point has been stressed by the officers of the California Section that while this is primarily a convention of the California group, all water works men and others interested in the topics to be discussed are cordially invited to be present and to participate in the discussion. Here is the way Paul Magerstadt, secretary of the section, puts it in his latest bulletin on the convention:

"You and your associates are invited to come, renew and add to your acquaintances among the water works fraternity. The personal contact will benefit you, your business and profession. Pass the invitation along. If you are interested, come. You are welcome whether you are a member or not, and lastly, remember the ladies are invited. It will be a splendid trip for them and special arrangements have been made for their entertainment."

The San Diego Hotel is the official headquarters of the convention and word has come from the manager of the hotel that accommodations at the hostelry were sold out for the convention early in October. It is, of course, desirable to keep the delegates together, but San Diego has a number of other first class hotels where accommodations are available. The San Diego Hotel will, however, be the scene of the official dinner and dinner dance.

A bang-up good entertainment program has been arranged by those in charge of this feature of the convention. Dudley's famous "Orpheus Four" whose singing gave the convention so much pleasure at Sacramento two years ago and again at Santa Cruz last year will again entertain at San Diego.

Here are the officers of the California Section of the association and the committees that, with the co-operation of the general membership, are going to put the 1926 convention down in history as the lucky seventh—the best ever:

The Program

THURSDAY, OCTOBER 28

Forenoon, 10:00 A.M.: General Get-together Registration and Review of Exhibits.

Afternoon, 2:00 P.M.: Address of Welcome by Hon. John L. Bacon, Mayor of San Diego.

2:15 P.M.: "Description of the Impounding Works of the San Diego Water System" by R. C. Wueste, Supervisor of Impounding System, San Diego Water Department (Questions).

2:45 P.M.: "The Biological Control of Impounding Reservoirs" by Dr. Carl Wilson, Director of Biological Laboratory, Bureau of Water Works and Supply, City of Los Angeles (Questions).

3:15 P.M.: "Report on Water Meter Maintenance Methods" by J. H. Flagg, District Manager, Pacific Gas and Electric, San Joaquin Division, (Discussion).

4:00 P.M.: Five minute papers and discussions.

Evening, 6:30 P.M.: Informal Dinner, Banquet Room, San Diego Hotel. Business Meeting; Report of retiring officers; Report of committees; Election of new officers; Selection of next place of meeting. Address by William Mulholland, chief engineer of the Department of Public Service of Los Angeles on "The Colorado River Project."

FRIDAY, OCTOBER 29

Forenoon, 10:00 A.M.: "Progress in Electrolytic Chlorination at Sacramento Filtration Plant" by Harry N. Jenks, sanitary engineer, City of Sacramento (Questions).

10:30 A.M.: "Corrosion Problems of a Water Supply System and Methods of Protection" by E. B. Stewart, electrolysis engineer, East Bay Water Company, Oakland (Questions).

11:00 A.M.: "Equitable Charges for Automatic Sprinkler Connections" by Major William Cartwright, automatic sprinkler engineer, National Board of Fire Underwriters (Questions).

11:30 A.M.: Five minute papers and discussions.

Afternoon, 2:00 P.M.: "Underground Waters and Pumping Therefrom" by George W. Trauger, superintendent, Lindsay Strathmore Irrigation District and Edmund K. Barnum, engineer, Fresno City Water Corporation. Presented by Mr. Trauger (Questions).

2:30 P.M.: "The Duty of Water in General Municipal Uses" by Charles Lee, consulting engineer, San Francisco (Questions).

3:00 P.M.: "Iodine in Drinking Water" by C. G. Gillespie, director of state board of health, Bureau of Sanitary Engineering (Questions).

3:30 P.M.: Five minute papers and discussions.

FRIDAY, OCTOBER 29

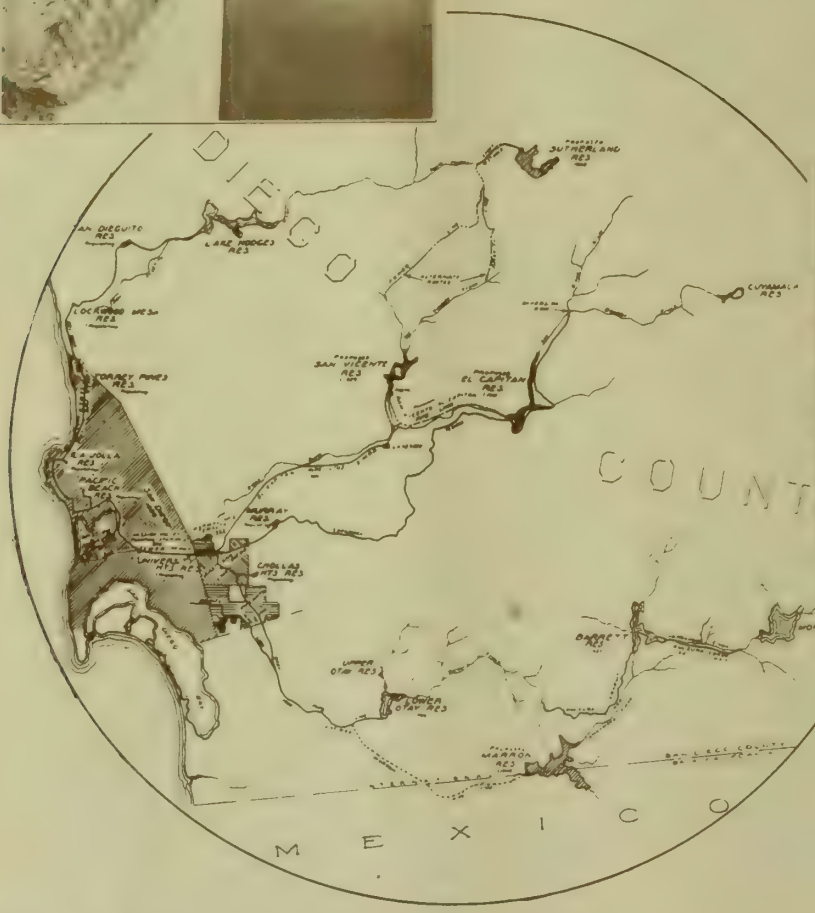
Evening, 6:30 P.M.: Dinner Dance, Informal, as guests of the Manufacturers in the banquet room, San Diego Hotel.

SATURDAY, OCTOBER 30

Morning, 10:00 A.M.: Leaving San Diego Hotel promptly at 10:00 A. M., automobiles will leave for trip to Lower Otay Dam and other points of interest of the San Diego Water System. Lunch will be served as guests of the City of San Diego at the Lower Otay Filter Plant. Return to hotel about 4:00 p.m. Ladies invited.

San Diego—the Host City Plans Its Water Supply for Decades Ahead

By FRED A. RHODES
City Manager of San Diego



This section of a map of San Diego County shows a comprehensive picture of the "Rhodes Plan" of water development for the city, by which it hopes to keep its water facilities a step in advance of population. Table I, on the following page, presents key facts respecting each of the projects represented on this map. INSET, LEFT: Barrett Dam, one of the largest projects in the plan, with a reservoir capacity of 14,498,000,000 gallons. INSET, RIGHT: Lake Hodges Dam, with its reservoir capacity of 12,000,000,000 gallons.

THERE is probably no other city of consequence in the United States, if not in the entire world, where such a peculiar combination of natural conditions and complications of circumstances unite to intrigue the ingenuity of the hydraulic engineer, as in the city of San Diego.

Time was when people up-state and elsewhere held the conviction that San Diego had plenty of climate and wonderful recreational facilities and scenic attractions—was a fine place to live in, but—*not enough water*. "Let San Diego get sufficient water and watch her grow!" was the exclamation of her well-wishers. Well, she is growing and she has the water. Now we'll go on with the story and prove it. And we'll tell what we are going to do.

Whenever the subject of water development is mentioned in connection with San Diego, one acquainted with the history of Southern California instinctively recalls the old romantic days of early Spanish settlements, and the pioneer struggles of the earnest Mission Fathers—history that extends back for more than a century and a half and embraces the earliest settlement in the United States. This was at 'Old Town' where, in the old halcyon days, ample water for the simple needs of the good people was readily obtained from convenient wells in the center of town.

First Irrigation System

From all accounts there were, even then, years when no rain came and periods when the nearby country was sadly in need of sufficient moisture to provide for stock and, as the community grew, it became necessary to sink additional wells in the bottom lands of Mission Valley, where the ground water was replenished by flood discharges of the San Diego River.

Later, but still more than a century ago, when the mission was established at Alta, by Father Junipero Serra, irrigation was conceived, and what is reputed to be the first irrigation project on American soil was instigated by the construction of the masonry dam across the channel of the San Diego River at Mission Gorge some ten miles upstream. From this diversion, well-constructed ditches, flumes and tunnels were built to convey the water over the fertile valley land theretofore unproductive for lack of moisture.

Such was the condition of affairs when "Father" (A. E.) Horton settled at the site of what is now San Diego—to the south of "Old Town" and on the shores of San Diego Bay. This new community at first depended on water hauled from wells at Old Town; later wells were sunk at more convenient places in the settlement itself; but the rapid growth in population soon required

a more substantial supply, and we come to the first organized effort to provide a water work system.

San Diego's Topography

Without attempting even a general description of the topographical and geological features of San Diego County it can be stated that it is divided into two principal districts; first, a series of terraces or mesas rising in steps from the ocean shore and extending from ten to twenty miles inland, gradually rising in elevation to a distance of as much as twelve hundred feet above sea level; second, a rugged mountainous area extending from the mesas easterly to the Imperial Valley. A considerable portion of this upland area rises to an elevation of four thousand feet or more above sea level, while an appreciable amount, around the higher peaks, reaches an elevation of six thousand feet, or higher.

The principal stream courses reach the sea through broad shallow valleys across the mesa lands, while in the mountainous area, with the exception of a few broad upland valleys, the streams flow in narrow precipitous canyons or between steep sloping hills. Occasionally, however, the larger water courses will broaden out into fair-sized valleys for an appreciable distance, and it is at these places that the good reservoir sites exist.

One of the outstanding features affecting the general water situation in San Diego County is the peculiarity of the climatic conditions, particularly the manner in which rainfall occurs from year to year. The average annual rainfall in the county varies from about nine or ten inches along the coastal belt, gradually increasing as higher elevations above sea level are reached, to fifteen inches and even twenty inches on the mesa land, and finally reaching as much as forty inches in the still higher mountainous area. The fairly steep slopes, found altogether in the mountainous area, combined with the rather barren character of a large portion of the catchment basins, are conducive to flashy runoffs and rapid accumulation of precipitation in the drainage channels.

Hydrography Records Interesting

Historical records indicate that the years of 1811, 1822, 1832 and 1842 stood out noticeably as flood years. The many recent records of the United States Weather Bureau show that 1874, 1884, 1895 and 1906 were all years of high flood discharge, while 1926 has again been a fairly high flood year. Saving floods can be relied upon to replenish the water supply at least once in ten years. The problem of providing a water supply and utilizing to the best advantage all the resources available to the city, while in no way a simple one, therefore narrows down to the construction of ample storage reservoirs to obtain the water when it is available, for use during the extended periods when the annual runoff is small.

TABLE 1—GENERAL RESERVOIR STATISTICS

Date Available to City	Name	Type	Stream	Height Above Stream Bed in Feet	Area of Water Shed in Sq. Miles	Area of Reservoir in Acres	Maximum Capacity Gallons	Net Safe Yield Gallons Per Day
1906	Upper Otay	Concrete Arch	Otay River	70.5	20	139.50	835,700,000	500,000
1906	Original Lower Otay	Rock Fill Steel Core	Otay River	132.0	85.7	809.2	11,638,300,000	1,900,000
1913	Original Morena	Rock Fill Concrete Face	Cottonwood Creek	146.0	119.5	1284.0	13,443,800,000	
1919	Rebuilt Lower Otay	Gravity Arch	Otay River	149.0	85.7	1301.1	18,979,500,000	3,300,000
1920	Hodges	Multiple Arch	San Dieguito River	130.0	300.0	1317.0	12,316,500,000	3,000,000 (to city)
1922	Barrett	Gravity Arch	Cottonwood Creek	170.00	130.05	881.6	14,512,200,000	4,400,000
1923	Enlarged Morena	Concrete Top Wall	Cottonwood Creek	155.0	119.5	1475.0	17,492,800,000	4,000,000
1925	Cuyamaca	Earth Fill	Boulder Creek	93.5	1.0	978	3,777,000,000	1,000,000 (to city)
1928	Sutherland		Santa Ysabel Creek	160	33.0	330	8,749,340,000	6,000,000
1929	San Vicente		San Vicente Creek		74.9			13,000,000
1931	El Capitan		San Diego River		190.0			12,000,000
1940	Marron		Cottonwood Creek		220.0			10,000,000

NOTE: Above given Net Safe Yields are at reservoir and do not include Transmission Losses

Any discussion of San Diego's water supply would be incomplete without at least some mention of the underground water in Southern California. The scarcity of perennial streams and the flashy runoff of the principal water courses has led to the exploitation of underground water resources to a degree not exceeded in any section of the United States.

Extensive studies of this source of supply have been carried on for years, and it is now well recognized that, at least within certain limits, the gravel filled valleys along the natural streams constitute more or less perfectly defined storage reservoirs; basins which are replenished annually by the stream discharge and surface runoff, and which are capable of being controlled in much the same manner as reservoirs above the ground.

To a certain extent, anyway, rights can be and have been established to the water supply thus afforded, and any contemplated control of stream runoff that might affect the replenishment of these basins must take into consideration the resulting consequences. This introduces still another feature that must be considered in connection with the development of water.

That the underground basins are valuable sources of water supply is well recognized by the city, which has already invested approximately one hundred thousand dollars in a series of wells, a battery of deep well turbines and a booster plant located in Mission Valley. A further development is now contemplated in the vicinity of Riverview, farther upstream on the San Diego River. Both of these plants promise to be vital safeguards in time of water shortage.

Water Rights and Lands

No attempt can be made to discuss in a brief manner the many complications arising from conflicting water rights. Like the poor man's dog, they seem to be ever present, especially in a community where water is valuable, and San Diego County is no exception.

Of all the western states, California is the only one where riparian rights receive much recognition, but in view of their standing in this state they must always be given consideration in planning a development. Thus the construction of storage reservoirs, or the diversion of water from one stream drainage into another, may seriously affect the water supply for riparian lands.

On this account the city has already purchased a considerable acreage of land in connection with the system now developed and is constantly purchasing additional land to safeguard future developments. Without attempting to cover this subject in detail it can be said that, at the present stage of procedure, the city has established what is believed to be unassailable title to all water necessary for many years to come and has successfully defended its interests against all adverse claimants that materially affect future development. Also, through the purchases of land now made and the options now held on additional lands, the principal interests of riparian water necessary for carrying out future development are under control.

Some Charts and Tables

Before proceeding further, reference is made to the several charts, maps, and diagrams presented herewith. On the

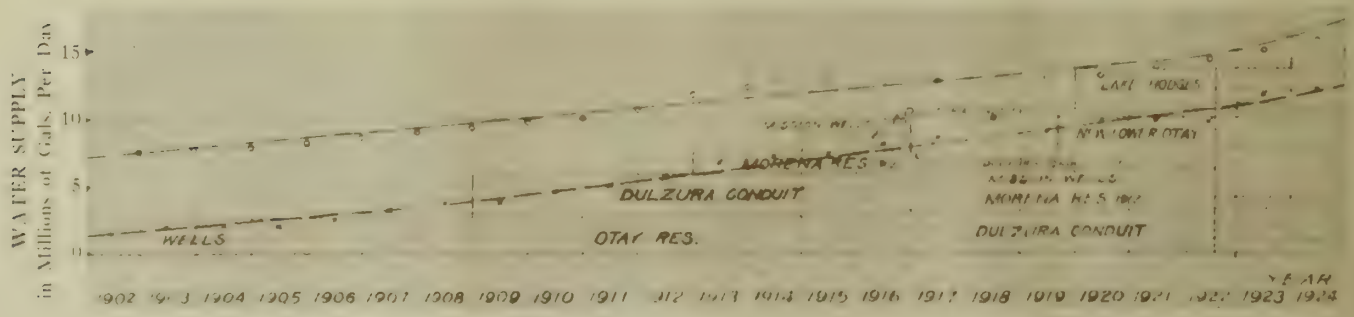
map reproduced on the first page of this article is shown the constructed water supply system to date, including the various reservoirs and conduits; also the proposed future development, under the plan of procedure now deemed most advisable. The years in which constructed units became available as sources of supply to the city, and the dates of completion proposed for the new work are also indicated in Table I. This table also gives the essential features of the different dams and reservoirs, both constructed and proposed.

Table II, entitled, "Net Safe Yields of Water Supply, Water Consumption and Population Statistics" shows the population which the net safe yield of the developed system would provide for, at any period, on the basis of one hundred gallons per day per capita; the actual consumption records, as compiled by the city's Operating Department; and the estimated population of the city, as derived from the different sources indicated.

On the chart appearing on the second and third pages of this article, bearing the title "Population, Average Daily Water Consumption and Available Water Supply Developed, and Proposed Future Development under Rhodes Plan," is shown, graphically, how the increase in demand for water can be aproximated by a curve based on past records; how the future population can also be estimated in a similar manner, particular attention being called to the experience of the City of Los Angeles, which has been incorporated into the study of future population for San Diego; and finally, the manner in which the different stages of past development combine to increase the total safe net yields at different periods, and how the future development will continue to add to the city's total supply.

A Critical Period

Notwithstanding the improved water service after the city took over the system from the old Consolidated Water



Company, in 1906, the situation soon became critical on account of the rapid increase in population. In fact, the scarcity of water was so great that the future welfare of the city was seriously threatened.

In order to bring about a financially capable organization, the Mt. Tecate Land & Water Company and the Otay Water Company were consolidated, in 1906, and taken over under the name of the Southern California Mountain Water Company. The late John D. Spreckels was induced to become actively interested in a financial way, and with characteristic energy, proceeded to rehabilitate the enterprise.

Negotiations were entered into for the purchase of the project by the city, and in the fall of 1912 the city exercised its option, taking over the entire system with the exception of Morena Dam and the lands connected therewith. The city later, in 1914, took over the balance of the system, consisting of the Morena Dam and a considerable acreage of land adjacent to Morena Reservoir.

Having finally taken over the development of its water supply as a municipal enterprise, the city at once voted several bond issues for the purpose of further development and improvement.

Extensive investigations had been carried on for some time past and were still being made, for the purpose of formulating some general program that would provide more adequately for future requirements. Numerous plans for combining various reservoir sites into a new system were given consideration, and the best engineering talent of the country was called into consultation.

Special attention was given to the construction of dams at Mission Gorge and at the El Capitan dam site, on San Diego River, also to the construction of dams on San Vicente Creek and on Santa Ysabel River at the Sutherland site.

Recent Developments

In the meantime, the demands of the city were constantly growing, and to provide an increased supply during the interval necessary for bringing about the construction of new reservoirs, negotiations were entered into for the purchase of water from the Lake Hodges Reservoir, on San Dieguito River, which had already been constructed by the San Dieguito Mutual Water Company.

An agreement was entered into in January, 1920, whereby the city was to be furnished with a maximum draft of three million gallons daily for a stipulated rate of payment, and suitable transmission works were built to convey this supply to the city's distribution system. This transmission works involved the use of San Dieguito, Rockwood, Mesa, Torrey Pines, La Jolla and Pacific Beach Reservoirs, for control purposes between Lake Hodges and different portions of the city's distribution system. A booster station was also necessary at Torrey Pines. With this 3 m.g.d. addition to the city's water supply the total net safe yield available was increased to 13.72 m.g.d.

In 1924, arrangements were made for reclaiming the wash water from the Lower Otay filtration plant, which heretofore had gone to waste. This improvement restored .30 m.g.d. to the net safe yield of the city system and brought the total supply available up to 14.47 m.g.d.

On December 1, 1925, the city acquired title to the entire San Dieguito system and to all excess water appurtenant thereto over the requirements of the vested irrigation rights.

Again referring to the water furnished to East San Diego by the Cuyamaca Water Company, the 1.0 m.g.d. available from this source has been in reality an additional supply over and above all water heretofore given consideration. Thus, since East San Diego came into the city proper, the total safe net yield available to the city at the end of 1925 can be given as 15.47 m.g.d.

The 1926 program, which is already

Water Survey of San Francisco District Shows Urgency of Providing for Future

Many Peninsula Towns Have Reservoir Capacity for But a Few Hours' Supply, and Must Depend Entirely on Pumps

By CHARLES H. LEE

THE provision of an adequate supply of water for all purposes is a fundamental requirement of community life. Pure water is necessary for elemental domestic needs, and under modern conditions a plentiful supply is indispensable for the upkeep of municipal improvements, industry, and especially for fire protection. The schedule of the National Board of Fire Underwriters for grading cities with reference to fire hazard assumes a standard city with deficiency charges for departure from the standard. The absence of a water supply is represented by a charge of 1,700 points out of the total possible deficiency points of 5,000 provided in the schedule. The major importance of water supply from the fire-risk standpoint is thus apparent.

Among the requirements for a continued supply of water are a dependable source, unbroken supply mains, and reliable pumping equipment. As these are all more or less likely to suffer damage in an earthquake region, special precau-

tions should be taken to insure their safety from injury and to provide auxiliary supplies for use in case of damage.

Sources of Supply

The communities of the metropolitan area of San Francisco are at present supplied entirely from local sources, partly from surface streams direct, but mostly from winter runoff held in storage reservoirs, or from wells. The principal agencies supplying water within the metropolitan district with the approximate amounts now being delivered to city distribution systems are as follows:

	Million Gallons Per Day
Spring Water Co. (w. and r.)	41
East Bay Water Co. (w. and r.)	30
Marin Municipal Water District (r.)**	6
San Lorenzo Water Co. (wells)	3.4
Peninsula Water Co. (w. and r.)	
South San Francisco Water Co. (w. and r.)	
City of San Bruno (wells)	
City of Burlingame (wells)	
Total	80.4

*Wells and reservoirs.
**Reservoirs.

San Francisco is supplied by the Spring Valley Water Company from storage reservoirs on the Peninsula and at Calaveras in Alameda County, together with the flow of Alameda Creek supplemented by wells in Livermore Valley. The supply, as now augmented by additional storage at Calaveras, is adequate for present needs.

In one respect, however, the present water system of San Francisco is incomplete. The volume of reservoir storage available within the city is inadequate, as it represents but three days' supply. In the event of damage to the long pipeline from the Peninsula or the main pumping plants by earthquake or other cause, a serious shortage of drinking water might occur within the city, which it would be difficult to meet. This is a situation which the City Engineer has pointed out in official reports and in public statements, but no action has been taken to remedy it.

Ample Fire Protection

The fresh-water distribution system in San Francisco, together with the auxiliary salt-water fire-protection system covering the congested-value area of the city, affords ample fire protection. The lessons derived from the earthquake and fire of April, 1906, have been incorporated in the high-pressure salt-water distribution system, and the latter represents one of the best of its kind. Special features are included which adapt it to earthquake conditions, one of which is the well-maintained system of cisterns located in portions of the city where distribution pipes may suffer damage by earthquake.

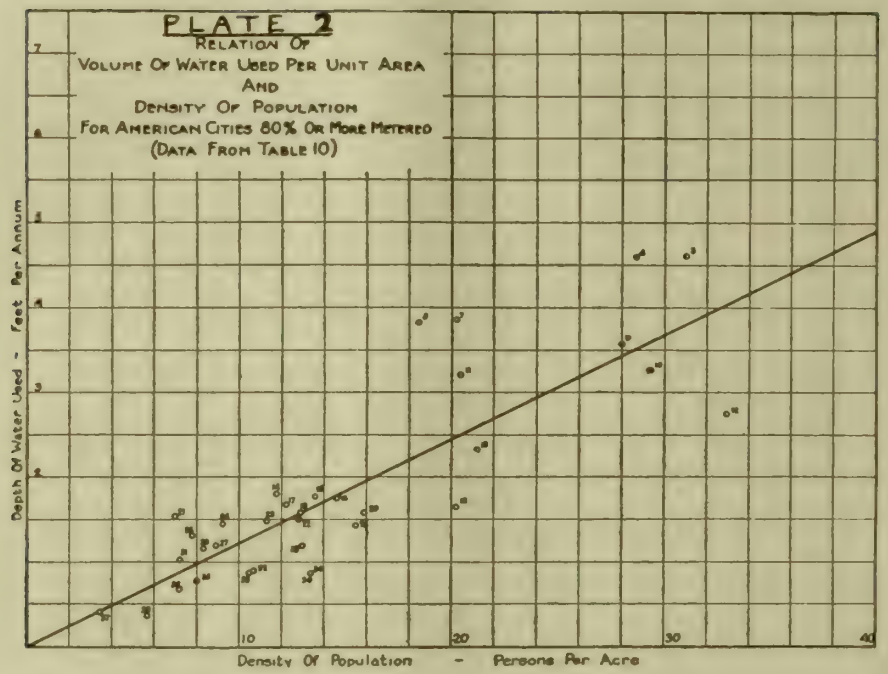
* Less than eighty per cent metered.
† Municipal boundary except as noted.
‡ Domestic service area.
§ Data from records published by American Water Works Association.

The nine East Bay cities are served by the East Bay Water Company. The supply is derived from storage reservoirs in the hills back of Oakland and Berkeley, and from wells along the shore of the Bay. With the recent rapid growth of the East Bay region and the long period of sub-normal rainfall extending over several years, this supply is no longer adequate. The East Bay Municipal Utility District is now actively engaged in bringing in an emergency supply from the lower San Joaquin River, and ultimately plans to extend its pipeline to a storage reservoir to be constructed on the Mokelumne River in the Sierra Nevada foothills. This system when completed should fully meet all local requirements.

Much of the built-up area of the East Bay region has not had adequate fire protection because of small distribution pipe capacities. Steps are now being taken partially to remedy this condition. A small capacity auxiliary salt-water system serves the congested value area of Oakland, but no other area is thus served. In case of a long interruption of flow through the main supply lines, due to a break or injury to pumps, a serious shortage of water for all purposes would occur. This is due to insufficient storage capacity at points within the service area, especially within the higher service zones. There are twenty-seven pressure zones, and pumping from main supply lines through equalizing reservoirs is required to serve the higher levels, as well as to maintain flow in the supply



lines themselves. In some instances water is pumped seven times before reaching consumers. Although the combined capacity of all reservoirs within the distribution system is sufficient to furnish nine days' supply, yet the actual supply in storage at any time is seldom up to full capacity. Furthermore more than eighty per cent of the capacity is represented by three reservoirs. Many of the pressure zones have barely a day's supply in storage, and, in case of serious crippling of pumping plants, would soon be without water.

The Marin County towns are well supplied by the Marin Municipal Water District, which obtains most of its water from storage reservoirs on the north slope of Mount Tamalpais. The District is developing its sources and extending its lines to meet all demands.

Situation on the Peninsula

Communities on the Peninsula, taken generally, are at present inadequately supplied with water, and are doing little to provide for the future. This region is building up rapidly, and is already beginning to feel the effects of inadequate water supply. Most of the towns draw their water from wells. The absence of normal replenishment of the underground supply from local rainfall and stream flow during the past eight years, combined with greatly increased drafts upon the supply, have caused the water level to drop many feet below the lowest stage ever previously experienced. The pumping level over large areas in some of the most highly developed portions of the Peninsula is nearly one hundred feet below the surface of the Bay, and in some districts exceeds this.

The varied demands upon the supply made by municipalities, industries, commercial agriculture, and private estates, have increased so rapidly the past few years that a return of normal winter rainfall will do little more than slightly retard the lowering of the water level. Conditions are rapidly approaching a point where the water-bearing gravels will either be completely drained to bedrock or pumping will become too expensive. In addition, there is the constant menace of salt water being drawn into the gravels from the Bay and rendering the water unfit for use. The date is past due in this area when definite steps should be taken to provide for future needs.

Many of the Peninsula towns have reservoir capacity for but a few hours' supply, and depend entirely upon pumps. In case of damage to pumping plants by earthquake, the supply might be cut off for a considerable period of time with serious consequences to the inhabitants.

Future Demand Discussed

The climate of the Bay region is almost semi-arid, rainfall being relatively small in amount and its occurrence confined to a few months of the year. Occasional years are also experienced when the rainfall is far below normal, sometimes several such years occurring in succession. The available natural water supply of the Bay region is therefore less than in humid regions, and more expensive to develop. The potential demand for water is also greater than in humid regions. This results from its greater use for domestic and municipal purposes, and its widespread use for home gardens and field irrigation. It is therefore important, in looking into the future of the Bay region, to ascertain the probable demand for water and its relation to the available supply.

The common method in use among hydraulic engineers for determining the future demand for water, is to analyze statistics of past daily per capita consumption for the community and similar communities comparably situated. This procedure, while satisfactory for single communities obtaining water from a common system, is not so well adapted to a metropolitan area including a number of separately served communities with diverse characteristics, as well as irrigated agricultural lands and industrial districts. For such areas it is more practicable to determine the volume of water

TABLE 2

consumed per unit of area such as the acre, or the depth of solid water delivered to the area in a given time if accumulated upon the surface.

Analysis of statistics of general municipal use on the latter basis furnishes a more logical basis for comparison of the amounts of water used by different communities, and also gives opportunity for direct comparison with use for irrigation which is always expressed as depth applied to the land. The writer for a number of years has been studying the use of water from this standpoint. He has had available the large amount of water-works data which have been assembled in recent years through the activities of the New England and the American Water Works associations and other similar organizations. He has obtained also many data direct from water-works officials, and has drawn from his personal observations.

Consumption Yardstick Evolved

These studies indicate that for American cities in which eighty or more per cent of the water is metered, there is a direct proportional relation between density of population and annual depth of water delivered to the service area. The general rule was found to apply in both eastern and western cities. The basis for this conclusion is indicated graphically on Plate 2, which was prepared from data assembled on Table 1. As is to be expected, there are departures from the average line, but the general trend is unmistakable. Los Angeles, for example, with its low water rates and extensive use of water for ornamental grounds and house gardens lies above the average line, while San Francisco, with its high rates and absence of gardens is considerably below. Similarly, Milwaukee with an unusually large consumption of water for industrial purposes is far above the line, while St. Paul, whose demand is mostly for municipal and domestic purposes, lies below.

In order to have a definite yardstick for comparison, the following tabulation has been prepared from Plate 2, and may be considered as representative for the average American city eighty per cent or more metered:

GENERAL MUNICIPAL USE

Density of Population Persons Per Acre	Feet Per Annum of Water Used	Density of Population Persons Per Acre	Feet Per Annum of Water Used
5	0.60	25	3.05
10	1.22	30	3.67
15	1.83	35	4.30
20	2.45	40	4.90

Corresponding data for net delivery of water for irrigation of general crops in various parts of California, as adopted by the State Engineer after a review of all available data,[1] are as follows:

County	Use of Water Depth in Feet Per Annum
Los Angeles and Ventura	1.75
Santa Clara, San Mateo, Alameda, and Contra Costa	1.50
Marin, Sonoma, Napa, and Solano	1.25

The following table gives additional data for individual communities in California and for different uses of water. The figures are determined for the actual area covered by each distribution system:

An interesting conclusion to be drawn from the data above is that California cities such as Los Angeles, San Jose, Palo Alto, Santa Rosa, etc., which are predominantly residential in character, with a large use for irrigation of house gardens and beautified grounds, and having low or moderate charges for water, lie above the average line for American cities (Plate 2). The East Bay cities, although residential in character, are an exception, being below the average. This is probably due to the high water rates and past shortages in water supply which have impressed the habit of frugal use upon consumers. These cities would doubtless come up to the average if provided with ample water supply at lower rates. San Francisco is also considerably below the average, due in a large part to the absence of gardens from the homes and the large apartment-house population, as well as high water rates (see Table 2).

Los Angeles' Experience

The experience at Los Angeles has been that, as irrigated lands are subdivided and become built-up residential prop-

Totals and average	876,600	6.5	5,690,500		1,074

* Thirty-three per cent of area deducted for dry farming and uncultivated land in determining water requirements; in other irrigated areas assumed uncultivated lands would be offset by losses in transmission systems and local storage.

† Golden Gate Park, Presidio, and roughest portions of Twin Peaks and Mount Davidson not included

STORAGE & DISTRIBUTION

Periodical Cleaning of Water Mains Saves Many a Bill for Replacements

Simple Cleaning Method is Tried with Considerable Success in Eastern Cities; Restores Carrying Capacity to within 5 Per Cent of New Pipe

By BURT B. HODGMAN, C. E.

EFFICIENCY of the underground water system involves two general topics. First the engineering study preliminary to the design, and after the design and installation, the up-keep, and the up-keep is just as necessary as the proper design. This up-keep or maintenance is most important to the safety of the community both for health and for fire protection.

If the future should develop science to the extent that instead of taking X-ray photographs of some of the unseen things, we were enabled to look into the earth and see the condition of the water system on which we have spent large sums of money, probably many superintendents would make haste to have them cleaned, but of course, out of sight out of mind controls this situation in many places, until necessity or the Board of Fire Underwriters appears. This board makes an examination and presto, the system is found wanting.

Whenever a large fire occurs in the city we frequently hear the report "lack of water pressure." What is this lack of water pressure? Usually it is nothing more than excessive friction due to corrosion or sediment in the mains which could be removed at a small cost.

Scale Reduces Capacity

What is the effect of the scale that is found in water mains? The first effect is reduction in the carrying capacity. Scale on the inside of the mains where the individual tubercles reach one-half inch in thickness will reduce the carrying capacity of 6-inch and 8-inch mains approximately 50 per cent or in other words you are getting one-half the value you would get if the mains were clean. Who would be content to get 7½ miles to the gallon with their automobile if at a small expenditure they would get 15 miles, but that is not all. When the Board of Fire Underwriters make their examination they say replace the 6-inch or 8-inch mains with 12-inch and 16-inch or perhaps larger or they will raise the premium rates of your insurance. Now in many cases if the present mains were kept in good condition there would be little cause for replacing or raising the premium rates.

OUT of sight, out of mind, is the way Mr. Hodgman describes the mental attitude of many water works engineers toward underground water systems—an attitude, he continues, that receives a severe jolt when dire necessity or the Board of Fire Underwriters intervene and call attention to lack of water pressure due to excessive friction from corrosion or sediment in the mains. The remedy then is not replacement, the writer asserts, but a thorough cleaning of the offending mains by methods found highly effective in many eastern localities, but little understood on the Pacific Coast. Mr. Hodgman, who is vice president and general manager of the National Water Main Cleaning Company, describes these methods in the accompanying paper, which was read at the Southwest Water Works convention at Shreveport, La., on October 12.

I know of one large city where the Board of Fire Underwriters laid out an extensive program for replacement in their heavy risk district and said if this program was not followed out their rates would be raised. Not one foot of these replacements was made, but they had my company clean the mains and after another examination they were given a clean bill of helth and no increase in rates.

Another Source of Saving

Another source of saving due to the cleaning of mains can be effected by reducing the power cost for pumping. An excess of friction in a pumping main increases the department's operation cost either in excessive cost of coal or other power.

Now what are the results from a sanitary standpoint? Investigation has shown that bacteria live and continue in sediment and scale in the mains in various places. When a city puts in a filtration plant and their mains are dirty, they seem satisfied to turn the clear water on and run it through these mains and so long as the water is clear everything seems to be satisfactory; but when there is a fire which creates increased velocity in the mains or perhaps changes the direction of flow, it stirs up the mud or scale and the citizens complain of the inefficiency of the filter plant while they may be getting bacteria also.

Cleaning Method Described

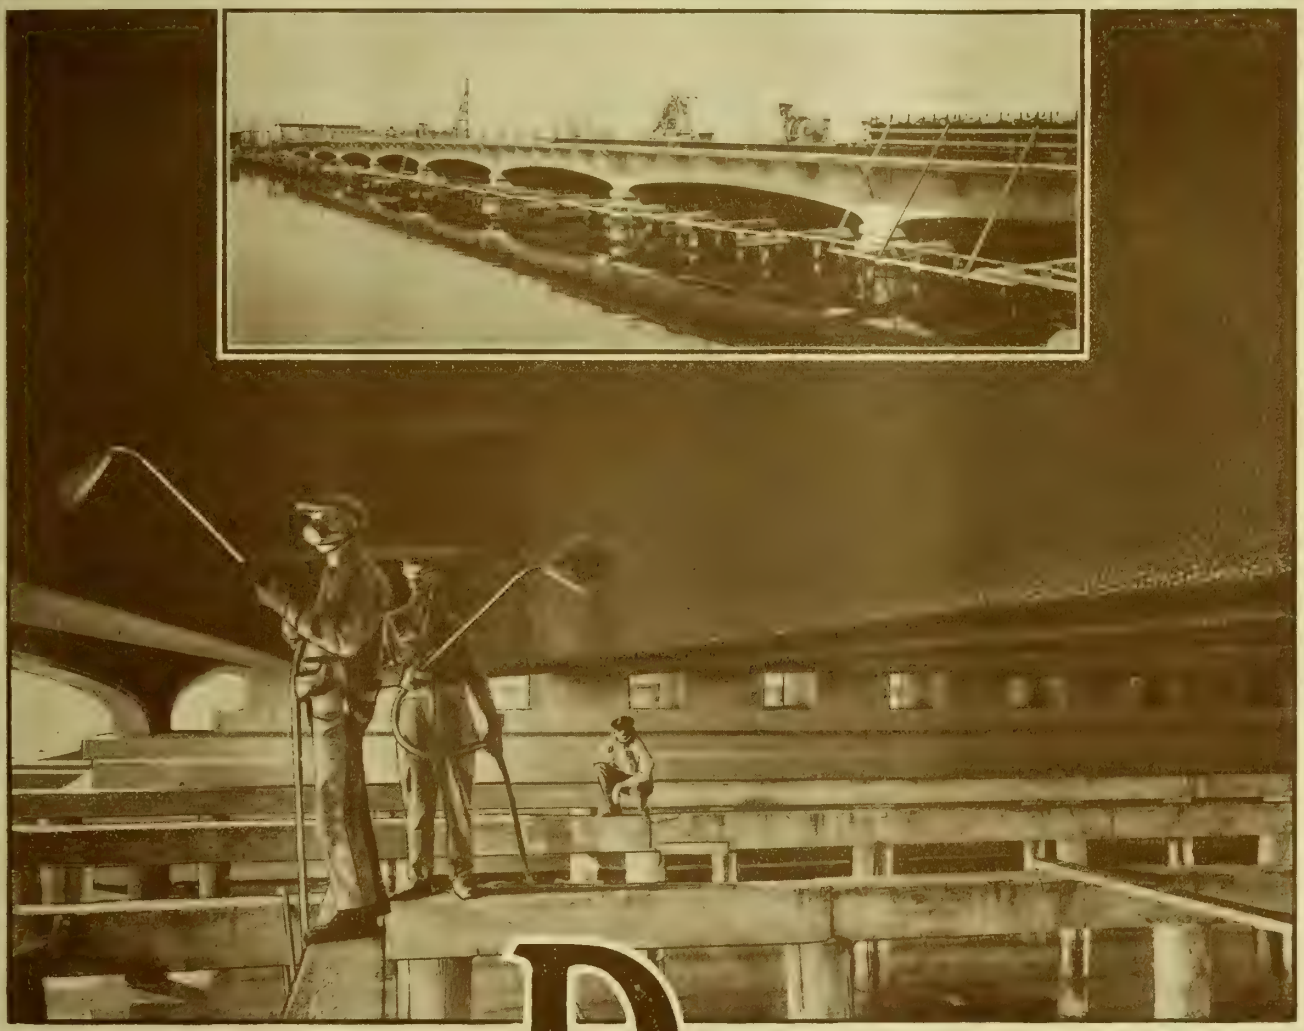
Several cities, when they have gotten a new water supply, have taken the precaution to clean out their entire system. This not only gives them adequate carrying capacity but cleans mains to transport potable water.

The method of cleaning is comparatively simple for those experienced in the art. It consists in cutting the main at two points, perhaps, 500, 1,000, or 1500 feet apart. In small mains a float is put through by the flow of the water and a cable is drawn through following the float. The cleaning machine is attached to the cable. This machine is pulled through the main with the water running to the riser pipe, giving the main a good flushing as well as scraping at the same time. The operation in larger mains is very similar except that no cable is needed because the machine is propelled by water pressure. Experience has taught us how to scrape mains to a degree where all of the foreign matter is removed but none of the tar coating is disturbed by the process.

Restore Original Capacity

We can guarantee to restore the carrying capacity of any main, which has originally been tar coated, to within 5 per cent of that of new pipe, but actually we restore the original carrying capacity of the main. The 5 per cent allowance is not for any dirt left in the main but is for irregularities of laying, special fittings, corporations cocks extending into the mains, etc.

A great deal of experience is required to learn this art as we know only too well. We have a force of superintendents who have been with us from eight to twenty years doing nothing but this type of work. We feel, therefore, that we are eminently qualified to meet every situation which comes up in water main cleaning and by our experience we have saved many cities a large outlay for replacements and for coal to pump against excess friction.



Damp Proof

Protecting the West Broadway Viaduct, Long Beach, from the ravages of salt air and moisture. This concrete viaduct is built over a portion of the harbor and is subject to a continual tidal wash. By the application of—

"McEVERLAST"
PROTECTIVE COATINGS

an absolute water-proof seal is obtained. These new coatings penetrate concrete to an unusual depth, forming an elastic coating unaffected by contraction or expansion. They repel acids, alkalies, salt air and water as well as all forms of sea life.

"McEVERLAST" Protective Coatings are applied cold, by brush, spray or dipping, as they are received in their containers. They are manufactured for application on metal, concrete, stone, clay products and wood.

Visit the McEVERLAST Booth. Mr. Logan Thomas will explain the HUNT Patented Process for curing concrete—one of the most revolutionary and "common-sense" developments in the history of concrete.

How San Diego Plans Its Water Supply

(Continued from Page 37)

well under way, consists of the construction of the so-called El Capitan pipe line, originally designed to extend from the University Heights Reservoir, the central distibuting point of the city's system, some twenty-five miles easterly to El Capitan Reservoir. The present construction contemplates the completion of the line as far as Lakeside, a distance of approximately seventeen miles. This line is to be 36-inch Lock Bar steel pipe, buried at all places except where it is carried on supports over coulees and across canyons, and equipped throughout with the latest type of appurtenances. All of the concrete piers have now been completed, and a substantial part of the trench work is finished.

Irrigation Water

Realizing the desirability of encouraging all possible farm development in the vicinity of San Diego, as well as in the entire county, and in order to promote a spirit of cooperation and harmony with the people of Riverview, the city has agreed to sell irrigation water to all land owners whose water supply may be in any manner impaired by the operation of the city's pumping plant. Future development by the city, therefore, will have the effect of insuring a bountiful water supply to the farmers, at all seasons of the year. At the same time the lowering of the water table and consequent improvement in under drainage will materially enhance the value of the land.

In connection with this development a filter plant, having a capacity of at least ten million gallons daily, will be installed at or near the booster pumps. The design of this unit will be such that it can be readily enlarged to handle all water ultimately developed about Riverview.

Further Dam Sites

Careful and lengthy consideration of many factors, and of a vast amount of data bearing upon the situation, conclusively indicates the most logical undertaking under the circumstances to be the construction of a dam at the Sutherland site, a conduit to carry the water from Sutherland Reservoir to San Vicente drainage, a diversion dam to take the water out of San Vicente Creek at Foster and a pipe line to connect the diversion dam with the El Capitan pipe line at Lakeside.

The available finances will permit constructing Sutherland Dam to its ultimate height and building the necessary conduit and other works, so that water can be at once conveyed through the connection with El Capitan pipe line into the University Heights Reservoir.

Therefore, instead of waiting upon the settlement of legal matters pertaining to the El Capitan development and the additional time required for the construction of the El Capitan Dam, or waiting until there are sufficient funds to undertake the construction of both Sutherland and San Vicente Dams, it appears most advisable to follow the program as indicated in the foregoing.

The development at Sutherland contemplates a dam approximately one hundred and sixty feet high. Some of the best known designers of dams in the country, such as Lars Jorgensen, Fred A. Noetzli, the Ambureen Dam Company, and others, have been called upon for designs; and, to insure the selection of the most economical, feasible and substantial structure, Arthur P. Davis, formerly head of the United States Reclamation Service and now Chief Engineer of the East Bay Municipal Utilities District at Oakland, California, has been retained, in a consulting capacity, to advise with the city officials in the selection of the most economical type of structure.

Carrying on as we are and up to the time San Vicente Dam is built, it is estimated that the city's water supply will be increased by approximately 6.0 m.g.d., which will then bring the total safe net yield up to 22.47 m.g.d.

At the close of the "ninth period of development" (1930-1931) the net safe yield of the city's supply should be 43.97 m.g.d., while at the end of the last period considered in the planning, 1931-1940) the total supply available would be 53.97 million gallons daily.

In conclusion, it seems pertinent to mention that, besides a definite program, hereinabove outlined, the city is constantly conducting studies and securing data relative to a number of other possible reservoir sites and water supplies. Long before the present program is carried to completion plans for further additions to the city's water system will have been perfected.

Mention may also be made of the well known and much advocated Colorado River development, which contemplates a water supply that will be available to all Southern California. Needless to say, San Diego officials are actively interested in this enterprise and are taking all steps necessary to safeguard the city's rights and interests.

Owing to the magnitude of the developments under way and contemplated, and to the importance of the work involved, a separate bureau has been organized to handle all matters pertaining to the city's water development program. The bureau is known as the Department of Water Development, Robert F. Cowles being the engineer in charge and Geo. B. Archibald being assistant engineer. Acknowledgment is duly made this department for the preparation of the preceding article and for the compilation of the several maps, charts and diagrams presented herewith. It is also desired to acknowledge the hearty cooperation and valuable assistance of R. C. Wueste, for many years supervisor of the city's impounding system, in furnishing operation data and other records of importance.

Review of California Section

(Continued from Page 15)

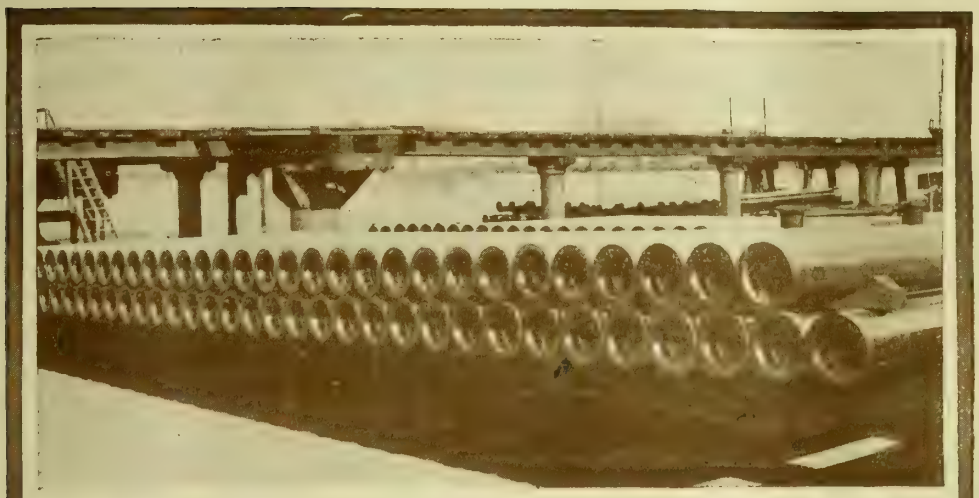
mund K. Barnum, engineer of the Fresno City Water Corporation, told the association about the Fresno system. Problems of design and distribution were discussed by George Read, of Los Angeles, in his paper on "Proper Arrangement of Plumbing for Buildings Higher Than Can Be Adequately Served Direct from Distributing System"; by J. E. Phillips, also of Los Angeles, who spoke on "Use of Balancing Reservoirs in Water Distributing Systems," and by Louis Stocklmeir, engineer, Pacific Board of Fire Underwriters, on the "Effect of Distributing Design Upon Fire Insurance Rates." S. B. Morris, of Pasadena, read a paper on "Types of Pipe and Water Main Construction," and R. L. Daugherty, professor of Mechanical Engineering and Hydraulics, of the California School of Technology, spoke on "Water Measuring Devices."

For those whose special problem was sanitary engineering, Dr. Carl Wilson, bacteriologist of the Los Angeles Bureau of Water Works and Supply, read a paper on "Reasonable Water Sanitation Requirements," and Gale S. Strout, Consulting Engineer of San Francisco, spoke on "Softening of Public Water Supplies." Charles Gilman Hyde gave an interesting recital of some of his European experiences, and Al C. Joy, publicity manager of the San Joaquin Light and Power Corporation, spoke on "Public Relations."

Officers were elected as follows: Chairman, Fred J. Klaus; Vice-Chairman, George W. Pracy; Secretary-Treasurer, S. B. Morris; Members of the Executive Committee, C. B. Jackson and P. Diederich, superintendent of the Public Service Department, Glendale.

Last Year's Meeting

Last year the California section met in its sixth annual convention at Santa



deLavaud Centrifugal Cast Iron Pipe

—is now ready to ship in sizes from 4″ to 20″

The principal features of deLavaud Centrifugal Pipe are:

1—Lower cost per foot.
2—Greater carrying capacity due to larger inside diameter. Its smooth surface produces less friction.
3—An even greater resistance to corrosion owing to its finer granular structure.
4—Cheaper to install owing to its uniform lead space and self centering bell.
5—It is easier to cut and tap.
6—Its greater strength and uniform section makes it valuable for use for higher pressures.
7—Adaptability to special joints due to its smooth exterior and uniform circumference.
8—It is made to be used with standard fittings and specials.
9—Annealing gives a uniform metal with no casting strains.
10—This method of casting leaves no possibility for sand holes or gas pockets.

Taking a National Treatment

THIS sounds much like a patent medicine advertisement. Why shouldn't it, for the National Water Main Cleaning Company has the remedy for inefficient water mains.

If the above 6-inch line could testify it would say that its carrying capacity had been increased three times after the many cubic feet of incrustation had been removed from its interior.

Let the NATIONAL METHOD doctor your municipality's sickly mains.

4360 WORTH ST. Ph: ANgelus 3331 LOS ANGELES

Cruz, on October 15, 16, 17. An attendance of 247 interested delegates from all parts of the state, combined with the excellent program, made the occasion a notable one. One of the most interesting features was the presentation of the Nicholas S. Hill cup, an annual award offered by a former president of the American Water Works Association to that regional section which has shown, during the year, the greatest growth in membership. F. M. Randlett, National Director of the A.W.W.A., attended the convention for the purpose of presenting this trophy to the California section, but the cup had been mysteriously mislaid in transit, and when every effort to locate it failed, Mr. Randlett made a graceful presentation speech, congratulating the Section upon its growth, and urging the organization to still further expansion, and awarding the cup as a recognition of the 1925 record—although no cup was at hand. The secretary reported that during the year twenty-eight members were added to the Section, of whom 22 were active, 2 corporate, and 4 associate members, bringing the total membership of the organization to 125.

Three Symposiums in 1925

The 1925 program was marked by three symposium discussions: "Service Installation Methods and Standards," "Meter Maintenance Methods," and "Jointing Methods for Water Mains." One of the noticeable features of these discussions was the freedom with which the delegates participated, exchanging experiences and comparing notes without restraint. The various papers read were noted for their practical ideas and the clearness with which they were treated. New officers elected for 1926 were: Chairman, C. B. Jackson; Vice-Chairman, S. B. Morris; Secretary-Treasurer, Paul E. Magerstadt, designing engineer, East Bay Water Company, Oakland; Members of the Executive Committee, John Burt and P. Diederich.

The great value of the organization, according to the members who have given their opinion, is that above all it has given an opportunity for the water works men to get better acquainted, to trade ideas and solutions to problems. As George W. Pracy expressed it, "These early meetings have given the waterworks men of California an opportunity to learn new tricks, to gain by the experience of others, to take action when necessary for the good of the business as a whole, and to work out plans for standardization which will benefit both the manufacturers and the buyers. If the association will continue to help the individuals in the waterworks business, I feel sure that it has ahead of it a long and useful life."

To prevent Corrosion, Tuberculation, Electrolysis

Corrosion-proofing in the Hetch Hetchy Water System with Biturine Enamel

DUMBARTON Aqueduct over S. F. Bay, a part of the Hetch Hetchy, the largest Water System in this country. Here the corrosive tendency of salt air and salt water had to be overcome. Both the steel bridge and the pipe line have been coated with Biturine Enamel.

BITURINE was also used extensively in other parts of the Hetch Hetchy project, including (as completed to date) 20 miles of 60″ riveted steel pipe, ¾ mile 42″ cast iron submarine pipe, and the penstocks of the 100,000 H. P. Moccasin Creek Power House, the largest hydro-electric plant in the world.

With the California Railroad Commission

Will Operate Domestic System

E. J. Whitney has applied to the California Railroad Commission for a certificate to operate a domestic water system in Tract 4782, Los Angeles County.

Pomona Will Take Over System

Consolidated Water Company of Pomona, California, has applied to the Railroad Commission for permission to sell its water system to the City of Pomona.

Grants New Rate Schedule

Fay Water Company, operating in the vicinity of Port San Luis, San Luis Obispo County, has been authorized by the California Railroad Commission to establish a new schedule of rates sufficient to permit proper maintenance of the plant.

Grants Maturity Date Change

In a supplemental order the California Railroad Commission today authorized Los Angeles Water Service Company to issue $385,000 of its six and a half bonds, maturing August 1, 1946, instead of June 1, 1946, as originally authorized.

Seeks to Issue Bonds

Roseville Water Company has applied to the California Railroad Commission for authority to create a bonded indebtedness of $200,000, and to issue and sell $180,000 of such bonds for the purpose of financing additions and betterments and to refund outstanding bonds.

Asks to Renew Loan

San Dimas-Charter Oak Domestic Water Company has applied to the California Railroad Commission for permission to renew a loan of $10,000, and issue notes to the San Dimas Water Company for $15,000 with interest at 7 per cent per annum, for a period of three years.

Asks Permit for System

H. T. Robinson, operating under the name of Ocean Park Heights Land and Water Company, has applied to the Railroad Commission for a certificate authorizing him to exercise a franchise to operate a public utility water system in the territory between Culver City and the Venice district of Los Angeles.

Authorizes Amended Mortgage

North Sacramento Light and Water Company has been authorized by the California Railroad Commission in a supplemental order to execute an amended mortgage and/or deed of trust guaranteeing payment of $60,000 of first mortgage six and a half per cent gold bonds heretofore authorized by the Commission.

Asks Meter Rates

Thomas Parkhill, operating a domestic water system in the Ridge Park Tract, Contra Costa County, has applied to the California Railroad Commission for permission to establish meter rates and for the Commission to prescribe its uniform Rules and Regulations for water service, and the limits of the service area of that utility.

Must Cut Officers' Salaries

Los Altos Water Company has been authorized by the California Railroad Commission to establish a new schedule of rates sufficient to meet maintenance and operating expenses, depreciation annuity, and a reasonable return on its investment under existing circumstances, providing that the allowance for salaries of its officers is substantially reduced.

Will Sell Land for Pipe Line

Port Costa Water Company has applied to the California Railroad Commission for authority to sell to East Bay Municipal Utility District a strip of land 100 feet wide beginning at Bates avenue in the Government or Gwin ranch and extending 2417.3 feet to Tormey avenue to be used as a right of way for a pipe line and other work of the Utility District, for the sum of $5,250.

Sells Plant at San Juan

Aaron Buchheim, operating a public utility water plant in the townsite of San Juan-by-the-Sea, Orange County, California, under the name of Buchheim Water Company, has been authorized by the Railroad Commission to sell and transfer said system for the sum of $15,000 to San Juan Water Company, and the latter company has been authorized to issue and sell at par, for cash, three shares of its capital stock of the aggregate par value of $300, and use the proceeds to pay organization and incorporation expenses.

Acquires Deer Creek Reservoirs

Nevada Irrigation District, comprising upwards of 200,000 acres of foothill and valley lands in Nevada County, has applied to the California Railroad Commission to fix the compensation to be paid Pacific Gas and Electric Company for the acquisition by the district of the so-called Deer Creek reservoirs and water ditches of Pacific Gas and Electric Company.

As the result of informal negotiations conducted by the Railroad Commission between the two principals, the utility company agreed to sell its water works to the district when organized, which proposes to extend an irrigation system throughout the territory of the district, thereby bringing under cultivation a large area of productive territory now without adequate water service.

Orders Service Restored

After an investigation into the operations of a public utility water system operated by E. L. McCapes in the town of Raymond, Madera County, the California Railroad Commission has ordered McCapes to reconnect and resume service to the premises of T. M. Nicolas, whose service has been discontinued by McCapes. Evidence produced at the hearing conducted by the Commission showed that service to Nicolas was discontinued by McCapes without warrant, despite the fact that Nicolas had been served continuously for twelve years. Nicolas appealed to the Railroad Commission for relief and the Commission directed McCapes to restore service to Nicolas pending an investigation. McCapes having disregarding the Commission's instructions the Commission began an investigation on its own motion with the result that a peremptory order to McCapes to restore service to Nicolas, was issued.

WHY LUITWIELERS FOR WATER WORKS?

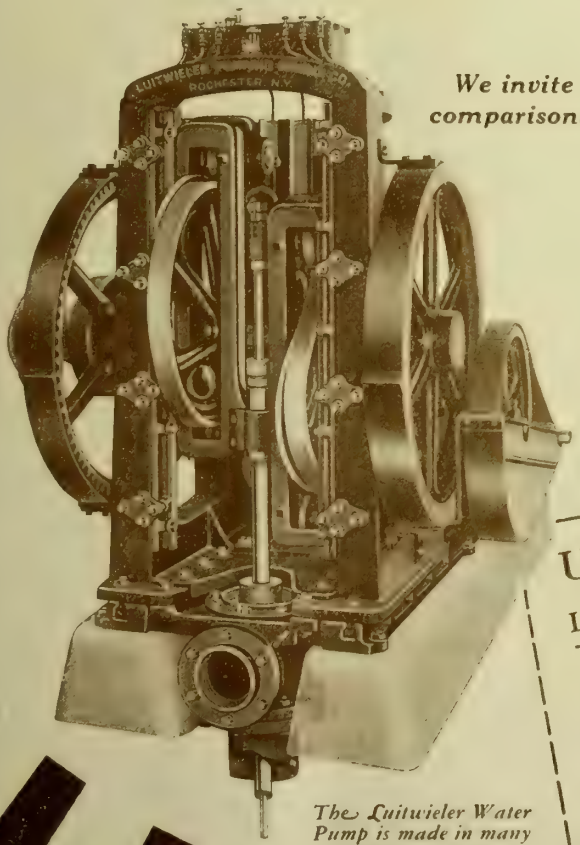
WE have a message of prime importance to water companies furnishing water to municipalities and communities, as well as to cities and towns developing their own supply.

Because first, the Luitwieler Pump, unit against unit, has no equal for efficiency-and we say this with full regard for the many good pumps on the market. And second, because water profits are the difference between water costs and the selling price regulated by the State. Every expense item lowered or eliminated makes this difference greater.

Mailing the coupon below can be the first step in adding to your revenue.

We speak with the authority derived from fifty years of pump experience.

Our engineers are at your service without obligation of any kind.



We invite comparisons

METERS & METERING

How the Los Angeles Water Department Is Solving Its Meter Problems

An Article That Discusses Many Phases of the Subject, Including Testing, Methods of Setting, and Repairing; Policy of Fairness to Users

By GEORGE READ*

WHILE anyone who follows the subject closely will agree that details of meter design and general practice do change with some frequency, it is possible there are not so many in the profession who realize that the basic principles of design and practice have remained practically unchanged for many years.

This fact was impressed on the writer not so long ago when he brought down from the files a paper on metering in Los Angeles that he had read before one of the early conventions of the California Section of the American Water Works Association. A rereading of the paper brought the realization that it was as up-to-date as though written the day before.

Of course, Los Angeles, which has established a world's record in its remarkable growth in population, has had and will continue to have its metering problems; but these, for the most part, are of a superficial nature, and the municipality, which purchased the properties of the old City Water Company back in 1902, can be said to have established a meter policy that might well serve as a model for other communities in the west. A discussion of some of the practices of the Los Angeles Bureau of Water Works and Supply might prove of interest to readers of this department of WESTERN WATERWORKS.

Store room and meter repair department of the Los Angeles Bureau of Water Works and Supply. The city uses several types of meters, two or three of which are shown in the foreground.

High Per Capita Use

Los Angeles always will have a higher per capita consumption than most eastern cities on account of its being a city of lawns and shrubbery which need watering about ten months out of the year. This per capita referred to covers metered services only. There is considerable water used outside of these for street washing and flushing, etc., and today this combined is estimated to make an average daily per capita consumption of 130 gallons, and reaches a high peak at times of 160 gallons. Due to the increase of apartment houses the number of consumers per service today is about 5.4.

During the first five years of public ownership of the water works, the city purchased several makes of meters, and from knowledge gained during this time the first set of specifications covering water meters for the city was written in March, 1907. From then on specifications have always been written and every improvement that would be advantageous to the city in prolonging the life of the meter has been embodied in these specifications.

In March, 1908, the Department purchased two 5/8 inch meters of all the different makes that could be had, and commenced a durability test. (The reason of the 5/8 inch size being chosen is that about 81% of the meters in service are of that size.) These meters were thoroughly tested before placing for the test, on two flows, one at the rate of two cubic feet per minute, and one at the rate of ten cubic feet per hour. They were then run steadily, night and day, at the rate of one cubic foot per minute, one-half their rated capacity. This rate was chosen so that no manufacturer could claim that the meters were being run beyond their rated capacity.

Test Took Over 2 Years

When the meters reached a registration of 25,000 cubic feet, they were taken off the line and again tested on the two flows, two cubic feet per minute and ten cubic feet per hour. The next test was made at 50,000 cubic feet recorded, the next at 75,000, and so on until the meter reached a registration of one million cubic feet. The meter was then taken off the line, ovehauled and made practically as good as when new. All the parts, etc., that were necessary to make the meter practically as good as when new plus the parts, etc., that were needed to keep the meter running to reach a registration of one million cubic feet, were charged up to the meter.

It took about two and one-half years to complete this test, and by means of it several weak spots were overcome. A meter under this kind of a test does not show the effects of corrosion as it would have if it had been in actual service, because water passing through the meter continuously tends to retard corrosion. Also the wear throughout the meter is not as great as if it had been in actual service, because the meter is running continuously at a steady pace and not subjected to hydraulic shocks through

*Superintendent Meter and Service Department, Bureau of Water Works and Supply, Los Angeles.

"Save the Surface and You Save All!"

EVERY Superintendent should keep this slogan in mind when buying water meters.

A thick, durable coat of tin protects the surface — external and internal — of every Hersey Domestic Water Meter. This protective coating is applied by dipping meter parts in a molten bath—not by the cheaper process of electro-tinning. It adds years of life to Hersey Meters. It is another proof of Hersey quality.

A Balanced Disc Piston which eliminates friction and accounts for the almost perfect accuracy of Hersey registration is another feature only to be found in Hersey Meters. These details of construction are of vital importance when you come to invest in new equipment.

turning off and on all the time.

All the makes of meters were working, however, under the same conditions, and the showings made were quite different in some cases. We consider that the knowledge gained paid well for the time and trouble and today we are still testing the same way.

Disk piston meters are used from ⅝-inch to 2-inch inclusive. For large office buildings, etc., requiring 3 and 4-inch meters, where the consumption as a rule is steady and where sensibility is the important factor, an oscillating piston type of meter is used. So far this type of meter has given the city the best service for this kind of use. It is expensive but dependable. Large services for fire protection, supplying only sprinkling systems, are not metered.

We consider it an imposition upon the consumer to install at his expense a large costly meter which might do harm and certainly do no good as far as the consumer is concerned. We insist on the piping from fire services being entirely separate from the domestic supply and we endeavor to inspect these services yearly, by shutting off the domestic supply and going through the premises. If we find water anywhere, it must be coming from the fire service. To date we have found only one case where this was really abused, and in that case the department imposed a pretty stiff penalty.

We are at this date strongly contemplating the use of check valves equipped with a regular 5-8-inch meter on a by pass for dection purposes on account it has become difficult, expensive and inconvenient to shut off the Domestic supply of a large building to make an inspection.

Services supplying sewer flush tanks are being metered with Jet meters as fast as time and funds will permit. We have 6841 of these connections, including San Pedro, and at this date 3948 are Jet metered.

The water is discharged into the tank through a hard vulcanized rubber disc and is calibrated to discharge as nearly as possible 300 gallons in twenty-four hours. It is impossible to make the calibration perfect for this amount in a given time, due to pressure variation.

There are several good water meters on the market today and, in fact, all meters are better than they were a few years ago.

As we are not bothered with freezing, our meters as a rule are set just inside the curb. They are placed on a riser from the service so that the face of the register is about 3 inches from the surface. This makes the reading of the meters and the changing of inactive meters, etc., easy and quick, and it also allows the use of an inexpensive shallow meter box.

New meter repair shop of the meter and service department, Los Angeles Bureau of Water Works and Supply. The view shows a close-up of several types of meters used by the city, which up to this time has not standardized on any one type, experience having proven that certain types are more suitable for certain installations than they are for others.

We have a local building ordinance which prohibits basements under sidewalks extending further than 3 feet from the curb. This strip was reserved by the city for the installation of fire plugs, meters, electrical conduits, and other public utility equipment.

We have a few meters in basements where the basement extends to the curb. These basements wer made prior to this ordinance. The few that we have are a nuisance. The meter-readers must get permission to enter, hunt keys and carry flash lights. Stuffing boxes are likely to leak and to cause damage. There is also a likelihood of a meter bursting and causing a great deal of damage.

When a large service must be metered in a basement we prefer a battery of 2-inch all bronze meters with valves governing the inlet and outlet of each meter. We consider a 2-inch all bronze meter not near as likely to burst as a 3 or 4-inch meter with main casing made of cast iron. In addition, if one meter stops operating it can be changed without shutting off the entire supply. Batteries have advantages and also disadvantages.

On services supplying large industrial plants, where at times it would be inconvenient and costly to the consumer to have the water cut off while changing the meter for repairs, we place a valve on each side of the meter and run a bypass pipe equipped with a valve around the two valves governing the meter. The bypass valve is left closed and sealed and when it is necessary to change the meter for repairs, etc., we open this bypass valve and then close the two valves governing the meter, thereby not interrupting the service.

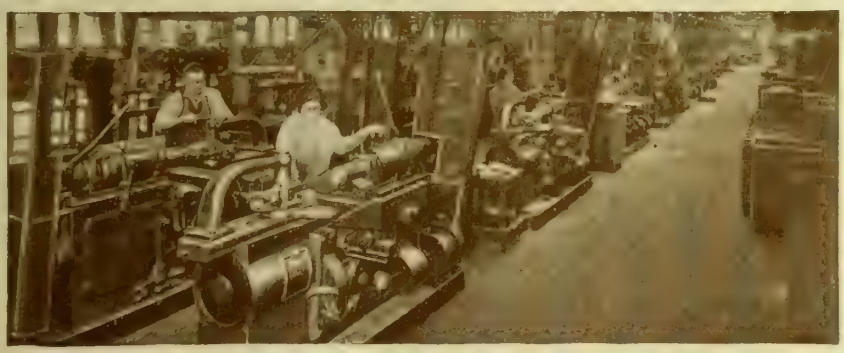
For covering meters in parkings, lawn or no lawn, a cement meter box 9 inches square by 11½ inches deep, is used—what we call our No. 1 meter box.

This box does not cover the curb cock and in fact we try to discourage the using of curb cocks by the consumer and recommend that they have a wheel valve placed by a plumber to control their water supply in case of needed repairs to leaky fixtures. The reason we try to discourage the consumer from using the curb cock is that in many cases they ruin them and frequently leave a hole dug out in front of the meter box which is a menace to the public.

We have specifications covering our curb cocks from one-half to 2-inch and they are standard all over the system. If any curb cock has to be renewed the space for the setting of the meter is retained. We also have a standard (fool proof) locking device for our curb cocks. By fool proof we mean that no curb cock can be clamped and sealed unless it is closed. Just before the world war broke out we were intending to cover meters in well kept lawns with a concrete meter box large enough to cover meter and curb cock both, and we still

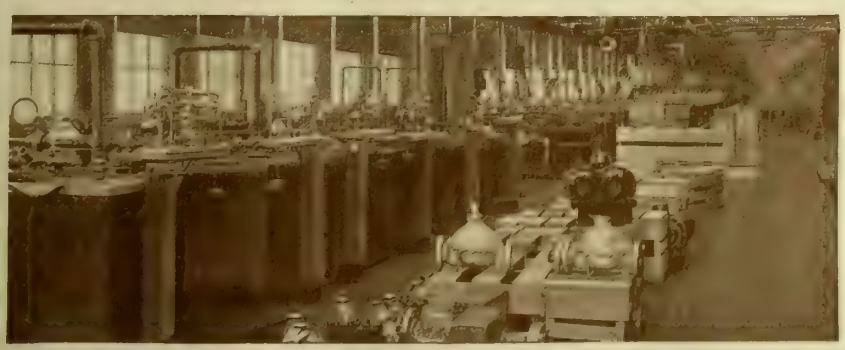
WORTHINGTON

A meter department ¼ mile long

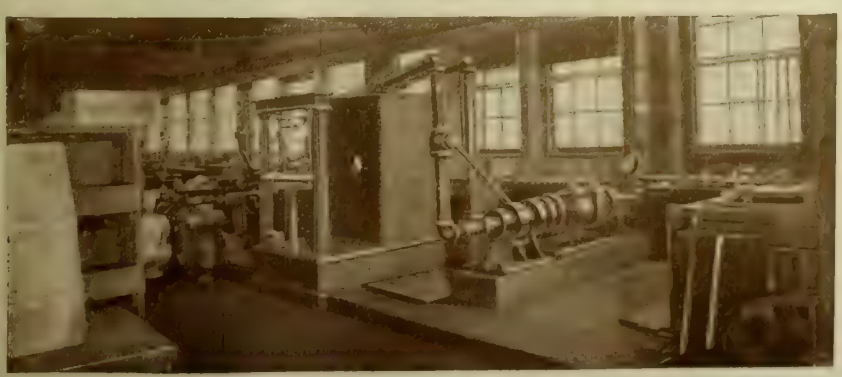


Turning brass parts for Worthington Meters

Large Meter Assembly Department



Small Meter Testing Department



Large Meter Test Stand

AN entire section — ¼ mile long — of Worthington's Harrison [N. J.] works is devoted exclusively to the manufacture of meters of all kinds.

That the demand for Worthington meters has necessitated a meter department of such extensive size is an indication of the widespread preference for Worthington Meters.

Stocks of meters and parts are carried in our branch houses in all parts of the country to insure prompt service.

intend to do this in the near future.

For housing meters set in cement walks we use a concrete well and a cast iron plate, large enough to house the meter and shut off. A wooden form made from 1x12 R. O. P. rabbited ¾x¾ is set in position and concrete poured around it. The plate then rests on the wooden form while the concrete is setting. Three sizes of plates are generally used as follows:

For covering ⅝ to 1-inch meters, the plate is 23½x15¾ inches, weighs 60 pounds and costs at this date $2.89 each. For covering 1½ and 2-inch meters, the plate is 30x22 inches, weighs 121 pounds and costs $4.35 each. For covering 3 and 4-inch meters, the plate is 46x26 inches, weighs 180 lbs. and costs $7.15 each. We also have a large plate, 64x26 inches, which we use at times to cover a fire-service gate and domestic meter.

When a sidewalk is being extended to the curb, taking in small concrete meter boxes that do not cover the curb cock, the Department requests the contractor to leave the top of the boxes level with the surface of the new walk and cement around them. Later on when the walk is thoroughly set, and it is convenient to the Department, a meter plate according to the size of the meter is laid on the sidewalk square with the curb, so that the meter register comes in the center of the plate. A hole in the sidewalk is then cut about a quarter of an inch larger than the plate, taking care not to crack the walk outside of the mark. The hole is excavated to about 3 inches below the bottom of the meter and the sides and ends of the hole extended about 2 inches under the walk. After the bottom of the hole is tamped, a wooden form is set covering the meter and the cut off. The plate is then set on the form and tamped down until the top of the same is level with the sidewalk. The plate is then removed and concrete is grouted all around the form to the surface. The plate is then put back and rests on the form while the concrete is setting. In time this wooden form rots away and leaves the plate resting on the concrete. A hole is left in the ends of boxes in case piping to the meter has to be renewed.

How Meters Are Tested

Meters are tested before they leave the factory, but to make sure they are correct the city again tests all meters before they are set. Our shop is equipped with modern testing benches for testing meters from 5-8-inch to 2-inch inclusive, and the water is discharged into tanks equipped with glass tubes on the outside. These glass tubes are equipped with buret floats on account of capillary attraction of water and are graduated in three stations, viz., beginning point, 5 cubic feet, and 10 cubic feet, which is stopping point. These buret floats have projections to keep them from adhering to the glass tube, and contain enough quick-silver to about half submerge them. The 5 and 10 feet stations are determined by weighing the water into the tank at 62½ pounds per cubic foot, so when a meter is tested the water is practically weighed through the tank readings.

These tanks were made tall and small in diameter to insure a big displacement for a small amount of water.

The register boxes of all meters are sealed after testing and no meter is taken from the meter shop for setting unless it is sealed.

We also have a large reinforced concrete tank which is also equipped with a glass tube and buret float and is used for the testing of larger meters, etc.

During the last fiscal year the Department tested an average of 3134 meters per month.

After meters are tested the water is pumped up to 100 lbs. per square inch to insure against leaking main casing gaskets and stuffing boxes.

When Customers Complain

A great many people really believe that water meters rob them by over-registering, and request that their meter be tested. We explain and try to talk them out of having it done, but sometimes the more we explain the more determined they are to have the test made. We then take their order and request that they or someone witness the test and tell them that if we find the meter over-registering, that there will be no charge for the test, and that we will rebate the back bills already paid. The charge for testing is as follows: ⅝ to 1-inch, $2.00; 1½ to 2-inch, $3.00; 3 and 4-inch, $6.00; 6 and 8-inch, $8.00.

The ⅝ and 1-inch meters are sometimes tested at the premises, by shutting off the water, taking the meter out and connecting it to the curb cock with a piece of hose. Then a meter of known registration on variable flows equipped with a valve on the outlet side is connected to the meter to be tested. Larger sizes are taken to the shop to be tested, leaving a new meter in its place, and if the meter being tested is low in registration or needs any repairing it is not put put back. In twenty years of experience I cannot recall over two cases where meters were found over-registering enough to warrant any rebate and those were very small.

We have yet to test a new meter that will describe an absolute straight line on variable flows. There is always a flow which shows a high peak of registration; because at this particular flow the meter is more positive in displacement than at any other; it does not show a loss through sensibility or a slippage by over-running. At high peak registration flows we aim to test and gear our meters and they usually leave the shop recording 98 to 101 per cent.

When a disk piston meter is new, one complete nutation or gyration of the disk means the passage of a quantity of water equal to the effective volume of the chamber. Any slight slippage due to the piston not perfectly fitting the chamber is taken care of by the change gears.

Vegetable Lubricant

After this meter has been in service for a few months and the draft has not been high and the water has been free from grit, etc., there appears a deposit of slick vegetable matter on the piston, and all over the inside of the measuring chamber. This deposit tends to lessen slippage and slightly reduce the quantity of water displaced by each nutation of the disk, hence the meter shows a slight increase of registration.

This kind of a deposit acts as a lubricant and tends to prolong the life of the meter. The increased registration through the meter is negligible and, as a rule, short lived, and the consumer has nothing to fear in this respect. On every meter that was taken out for not operating, due to being worn out, it is safe to say that the consumer got more water than he paid for.

The Department has some meters in service equipped with straight reading intermittent registers that require close watching. Most of these meters were acquired through the taking over of water companies by the city. This type of register can over-register at times, by one of the mutilated gears creeping back on its shaft and getting on the face of the counter wheel which drives it. This gear then becomes disengaged from the next higher counter-wheel which it should drive and leaves it free. The first counter-wheel is fastened on the shaft that the other wheels revolve upon and as this shaft revolves the disengaged counter-wheel at times creeps with it.

This intermittent straight reading register is gradually being replaced with the round dial constant moving type. This faulty construction, well known to us, is closely watched and before long will be a trouble of the past. If the consumer knew how careful the department is in regard to the testing of meters before they are set and what a remote chance there is for his meter to over-register, I think he would be perfectly satisfied.

Practically all meter repairing is done

WITH THE EXHIBITORS AT THE SAN DIEGO WATERWORKS CONVENTION

The exhibits of the manufacturers at the annual conventions of the California section of the American Water Works Association form one of the most impressive features of the meeting. Following is a list of those who will have exhibits at this year's convention at San Diego, Oct. 28 to 30, together with a brief description of their displays:

BYRON JACKSON PUMP COMPANY will have an interesting exhibit, showing a very modern built-in motor for deep-well pumping; a complete cut away section of deep well turbine pump; and a four-stage high duty bronze studded multiplex pump, with case opened up to show complete rotating element. L. A. Chenoweth will be in charge, and E. F. Lewis will also attend the convention.

CHAPMAN VALVE MANUFACTURING COMPANY will exhibit several different types of standard and low-pressure valves, which will be shown by Q. J. Magary, engineer of the Los Angeles office.

MUELLER MANUFACTURING COMPANY will feature in their exhibit copper service pipes and fittings. They will also have a full line of water pressure regulators and various water works fittings. W. L. Jett, manager of the Los Angeles plant, and T. F. Leary, manager of the San Francisco plant, will have charge.

WATER WORKS SUPPLY COMPANY, featuring especially the Leadite joint, will have on exhibit a Leadite joint that has been underground for 27 years. They will also show Simplex Air and Vacuum valves; Rensselaer gate valves, Corey fire hydrants; and Simplex Venturi meters. L. H. Chamberlain, manager of the Los Angeles office, will be in charge of the exhibit.

CALIFORNIA FILTER COMPANY, San Francisco, Los Angeles, and Seattle, will have on exhibition the various types of filters manufactured by them, as well as many photographs showing installations. Paul Bovard, assistant manager, will have charge of the exhibit.

FRANK J. KIMBALL PUMP COMPANY, Los Angeles, will feature in their exhibit samples and sectional parts of the Kimball direct flow turbine pump. J. K. Haigh, assistant sales manager, will have charge of the exhibit.

KENNEDY VALVE MANUFACTURING COMPANY. Kennedy valves and hydrants will be exhibited in detail, each sample showing the latest improvements. F. J. Henkenius, branch manager at San Francisco, and G. J. Reardon, the Los Angeles representative, will have charge.

McWANE CAST IRON PIPE COMPANY will feature their Pre-Calked Joint and will have pictures and models of cast iron pipe fittings and water works supplies. H. M. Dudley, Pacific Coast sales manager, with headquarters at Los Angeles, and A. Van Vechten, of San Francisco, will have charge of the exhibit.

MODERN IRRIGATION, published by Petroleum World Publishing Co., Los Angeles, will be represented at the convention by Owen Brown, president, W. C. Monroe, vice president, Russell R. Palmer, editor, and R. H. Thiess, special representative. Copies of the October issue, the special Waterworks Number, will be available.

NATIONAL METER COMPANY, New York, will show a full line of meters. One of their special exhibits will be a large displacement type meter, operating with water flowing through it, showing principle of operation of the meter mechanism. G. H. Bailey, Pacific Coast manager, Fred D. Webster, Sidney S. Small, Chas. P. Bergman, and M. J. Brooks will be in charge.

NEPTUNE METER COMPANY, manufacturers of the Trident Disc, Crest, Compound, and Protectus water meters, will have a complete line of meters on display. J. R. Barker, Pacific Coast manager, C. A. Braslan, T. J. Kells, A. H. Nye, and D. S. McFarland will be in attendance.

B. NICOLL & COMPANY, New York, will show samples of Pont-a-Mousson Cast Iron pipe and fittings. C. T. Claussen, Pacific Coast manager, and W. S. Conner, Los Angeles representative, will be in charge.

PACIFIC STATES CAST IRON PIPE COMPANY, will exhibit pictures and models of cast iron pipe, fittings, and water works supplies, which will be shown by H. M. Dudley and A. Van Vechten.

PHILBROOK SPRING PIPE CLAMP CO. will have on display the Philbrook bolted clamps and Stallard union. C. B. Meskimons and M. F. Prescott will have charge of the display.

UNITED STATES CAST IRON PIPE & FOUNDRY CO. will exhibit cement-lined pipe as well as deLavaud Centrifugal Cast Iron Pipe in a full line of sizes. They will also show various types of joints among which will be the Anthony joint which will be new to the trade. R. W. Martindale, Pacific Coast manager, A. R. Housmann, and Lee H. Chamberlain will have charge of the exhibit.

C. W. SIRCH, Los Angeles, will exhibit the Sirch filters and a line of swimming pool fittings, which will be shown by Chester D. Walz.

WALLACE & TIERNAN COMPANY will exhibit various types of Chlorine Control Apparatus for water purification, and Chemical Dry Feeder Apparatus. The operation of the equipment will be explained by Alexander Bell, Pacific Coast representative; Wm. J. O'Connell, Jr., engineer of the San Francisco office; G. T. Luippold, manager of the Los Angeles office, and A. L. Frick, Jr., engineer of the Los Angeles office.

WESTERN PIPE & STEEL COMPANY will have a large exhibit featuring Lock Bar, riveted, and welded steel pipe, Well casing, Tower tanks, Steel water tanks, and Storage tanks. They will also show different methods of protective pipe covering. A number of representatives of the company will be in charge, including L. N. Slater, W. B. Stanford, H. G. Tallerday, Roy Koster, H. A. Walter, W. G. Gates, and R. D. Plageman.

WAILES DOVE-HERMSITON CORPORATION, New York. S. J. Porter, Pacific Coast manager, will show samples of Bitumastic.

WORTHINGTON COMPANY, INC., will feature a complete line of cold water meters of Disc and Turbine type. The exhibit will be in charge of Arthur Crooke, of the Los Angeles office; F. T. Shoemaker, San Francisco, and Wm. Gustafson, Los Angeles.

R. W. SPARLING, Los Angeles, will have

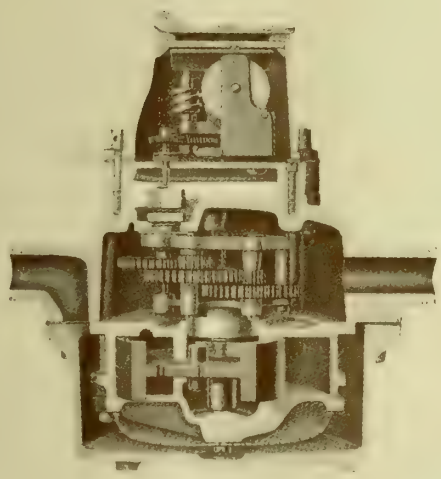
THE SUPREME METER

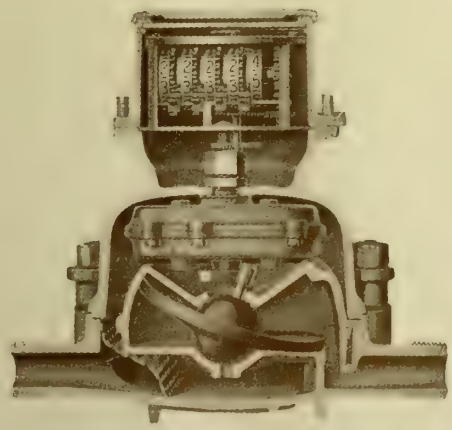
for water works service



EMPIRE METER

THE EMPIRE OSCILLATING PISTON type of meter is made in Sizes up to and including six inches. Their accuracy in even the largest sizes is often described as "astonishing." They are equally valuable for their lasting qualities and their low cost of upkeep.

We recommend the use of large EMPIRE METERS in place of batteries of small meters. First cost and maintenance lower—Accuracy greater.



NASH TYPE K METER

SIX TYPES IN ALL

With six distinct types, we are in a position to supply a meter for every exacting requirement. The Nash Disc Water Meter (shown at lower left) embodies every feature of merit to be found in any meter of this type. It is simple and substantial in construction. The excellence of this design has been proved by many years of successful service.

an interesting exhibit featuring recording gauges. One new to the trade is the Metrograph, to be used in connection with the meter to give a graphic record of the flow. They will show a Differential gauge, which records any loss of head through any orifice, and a Balance Flow regulating valve.

M. GREENBERG'S SONS, of San Francisco, will feature the following equipment: Greenberg standard single outlet hydrant; Greenberg steamer fire hydrants; Keystone type fire hydrants; Los Angeles new approved type iron body fire hydrants which can be repaired in the field; brass and iron fire valves and wharf hydrants; hydrant spanner wrenches and special hydrant connections, monitor nozzles, adapters, etc. The exhibit will be in charge of Stuart N. Greenberg, of San Francisco and Wm. S. Foster of the Los Angeles office.

GRINNELL COMPANY OF THE PACIFIC will have on exhibit the following: Grinnell detector check valve; cast iron pipe; underground socket fittings; hub-end gate valves; and Grinnell automatic sprinkler. J. S. Gibson, A. C. Hacker, and C. H. Chase will be in attendance.

HERSEY MFG. COMPANY, South Boston, Mass., will have on display their compounding valves and a full line of their meters as follows: Detector meter for fire service; compound meter; torrent meter and disc meters. The exhibit will be in charge of R. W. Keene and W. L. King, of the Los Angeles office, and Allen Jack of the San Francisco office.

HILL, HUBBELL & COMPANY, Technical Paint Specialists, will include in their exhibit specimen pieces of pipe and plates coated with their corrosion preventives—Biturine Pipe Dip, Biturine Enamel, Bitulumin (aluminum paint) and Number Two Fifty Iron Primer. The company believes this exhibit will have special educational value as these products have been widely used both in this country and abroad, in all sorts of climatic conditions. This company maintains offices in San Francisco, Los Angeles, Seattle, Portland, Baltimore, Tulsa, and New York City. The exhibition will be in charge of J. E. French and Francis Longley, from the San Francisco office, and Walter Ferem of the Los Angeles branch.

JAMES JONES COMPANY, Los Angeles, will have on display in their exhibit bronze corporation and service cocks, pipe clamps, gate valves, angle valves, and fire plug valves. W. W. Connor will be in charge of the exhibit.

AMERICAN BRASS COMPANY. The special feature of the exhibit will be Anaconda brass and copper pise for water services and Anaconda red brass flexible connections. A. W. Gruss, San Francisco agent, and G. T. Piersol will have charge of the exhibit.

COMMERCIAL IRON WORKS will show, in connection with Western Metal and Supply Co., a complete line of Butterfly valves, Flap valves, Check valves, and plugs and caps.

WESTERN WATERWORKS, Supplement of Modern Irrigation, published by Petroleum World Publishing Company, will be fully represented at the convention. Owen Brown, president, W. C. Monroe, vice president, and Robert H. Thiess, special representative, will represent the business organization, and Russell R. Palmer, editor, and Graydon Oliver, technical editor, will be on hand from the editorial department. Copies of the magazine will be available.

WESTERN METAL SUPPLY COMPANY, San Diego, will feature a full line of valves of Butterfly, Flap, and Check types, as well as plugs and caps.

WATER PURIFICATION

Contends Water Companies Cannot Make Own Chlorine to Advantage

Pacific Coast Authority Feels That Sacramento's Engineers Overlooked a Few Cost Items When They Figured It Was Cheaper to Make Own Chemical

By C. T. HENDERSON

IN THE July 29th issue of *Engineering News-Record* appears an article entitled "Home Electrolytic Chlorine at Sacramento," by Harry N. Jenks, Superintendent Pumping and Filtration Works, Sacramento, Calif.

If we take the figures stated in this article at their face value no municipality can possibly afford to buy liquid chlorine at 12½ cents per pound for water purification purposes but must, of necessity, produce its own chlorine on the premises.

Believing that the true facts were not altogether reflected in this article, or, in other words, feeling that Mr. Jenks' article represented one viewpoint rather than a bird's eye view of the situation, a complete investigation of the Sacramento installation was undertaken.

Question of Accounting

At the outset there was encountered the fact that municipal bookkeeping and bookkeeping as done by private enterprises are quite different, in that factors which are considered as expense items by those who must operate for stockholders' profits are entirely overlooked in municipal accounting.

The original Sacramento electrolytic installation consisted of Marsh cells which are said to have been totally unsatisfactory, and which were, consequently, scrapped. Of course, in private enterprise the capital invested in this original installation would have been charged up to experience, and interest on this capital would afterwards be carried forward as an item of cost in figuring unit prices of material produced until such time as the loss could be absorbed out of profits.

However, in municipal accounting the position is taken that the present operating staff cannot be held responsible for the mistakes of those who designed the plant; consequently the expense of installing and tearing out these Marsh cells is simply wiped off the slate and not taken into consideration in figuring present day costs of producing chlorine. While, of course, it is probable that such a mistake would not be made in subsequent installations, still, so far as the Sacramento installation is concerned, it cannot properly be said to be earning a profit for the municipality until such time as the cost of the discarded Marsh cell installation has been absorbed out of savings. These original Marsh cells were replaced with six diaphragm type cells designed and built by an employee of the filter plant, who had formerly been connected with the Hooker Electrochemical Co., and who was, consequently, familiar with the design and construction of chlorine cells. While no accurate data is available regarding the cost of these cells, it is probable their cost was not less than $300 each, making the investment in electrolytic cells now in use $1800.

CAN water companies and municipal water works manufacture their own chlorine cheaper than they can buy it? This is the question that has brought forth a spirited controversy in western water works circles since July last, following the publication of the article by Mr. Jenks (and mentioned herewith by Mr. Henderson) in the July 29th issue of Engineering News-Record. Mr. Jenks is slated to read a more lengthy report on this same subject at the San Diego convention and the topic bids fair to become one of the livest up for discussion on that occasion.

WESTERN WATERWORKS holds no brief for or against the proposition put forward by Mr. Jenks, believing that, in due course, it will be decided upon its own merits. At this time, however, in view of the prior publication of the article in question, and because of the great interest which it has aroused, we feel that readers of WESTERN WATERWORKS will welcome a full discussion of the matter by an authority who does not agree with Mr. Jenks' conclusions. Mr. Henderson, the author, is vice-president of the Great Western Electro-Chemical Company, and is well qualified to represent those who maintain that the Sacramento experiment is far from conclusive. Further data upon the subject of chlorine manufacture and costs will appear in a later issue.

—Editor.

Equipment Gets Good Care

The present cell equipment is operated under the most favorable conditions conceivable, in that it is being operated by its designer, who quite naturally bestows upon it the care and attention any man would bestow upon an equipment of his own design and construction. It is not probable that electrolytic cells in any ordinary installation would be as well looked after and maintained as are the electrolytic cells at Sacramento.

The motor generator equipment consists of 2300-ampere and 1600-ampere set, each set consisting of a Westinghouse 3-phase induction motor, direct connected to a 25 volt D. C. generator. While no accurate figures regarding the cost of these motor generator sets are available, it is probable that their total cost, delivered and erected, will not be less than $6,000.

The operating staff at Sacramento claims that 2½ KWH on the A. C. side of these motor generator sets will produce 1 pound of chlorine; the cost of electric power is 8½ mills per KWH. It is also stated that 4 pounds of salt at $7 per ton will produce 1 pound of chlorine. Further than this no specific statement is made regarding the details of the cost of production, nor any statement regarding the total cost of producing chlorine, other than the general statement contained in the article of July 29th that the total cost of producing varies from 5 to 7 cents per pound.

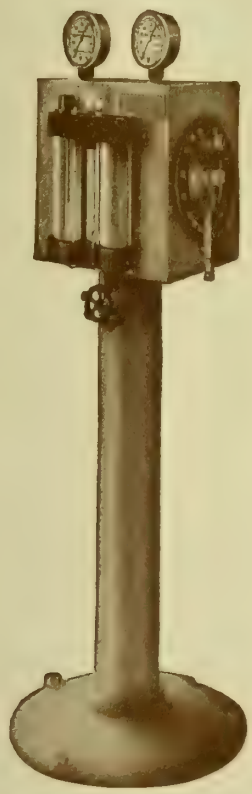
The annual production of chlorine at Sacramento amounts to approximately 15 tons.

Cost Items Omitted

Particular attention is called to the fact that no mention is made of the cost of diaphragms, which will amount to not less than $2 per ton of chlorine produced; nor is any mention made of the cost of anodes, which will probably amount to not less than $5 per ton of chlorine produced.

Again, nothing is said about the cost of labor, supervision or chemical control, apparently on the theory that labor, supervision and chemical control must be there for the operation of the filter plant, and no extra cost is involved in taking care of the electrolytic installation. The fallacy of this argument is so apparent as to call for no comment whatsoever. It is a mistake commonly made by those

Chlorination



Manual Control Solution Feed Chlorinator—Type MSP
A new rugged apparatus in which the Chlorine is measured under a Vacuum

has become standard practice for the sterilization of water,—the sanitation of swimming pools,—the disinfection of sewage,—the elimination of noxious odors,—and for many other purposes,—largely because of the accuracy and reliability of W&T Chlorine Control Apparatus.

¶ Chlorination of drinking water is not only unsurpassed community health insurance but it is downright good business insurance,—in view of the recent tendency of the Courts* to award damages to persons stricken with intestinal disease caused by polluted water.

*See Engineering News Record, Vol. 97, No. 1, p. 30.

"The only safe water is a sterilized water"

WALLACE & TIERNAN
COMPANY, INCORPORATED
NEWARK · NEW JERSEY

NEW YORK CHICAGO KNOXVILLE SAN FRANCISCO MINNEAPOLIS PITTSBURGH DALLAS KANSAS CITY

unfamiliar with cost accounting practices.

If we take the statement of the operating staff as being correct, then the true picture of operating cost is about as follows:

Direct cost per pound of chlorine produced:		
4 lbs. of salt @ $7	1.4	
2½ KWH @ 8½ mills	2.125c	
Diaphragm renewals at $2 per ton of chlorine	.1	
Anode renewals @ $5 per ton of chlorine	.25	
Total		3.875c
Indirect expense may be figured as follows:		
Maintenance cost on electrolytic installation at 33 1-3% per year	$600.00	
10% depreciation on electrical equipment	600.00	
Interest on capital invested at 5%	390.00	
Insurance at 1%	78.00	
Total		$1668.00
With an annual production of 15 tons chlorine, this amounts to $11.20 per ton or, per lb.		5.56c
Added to the direct charge of 3.875c per lb. as itemized above, total cost becomes, per lb.		9.436c

Apparent Saving Is $819.50

The annual cost of operating the plant with a production of 15 tons of chlorine will, therefore, be $2830. Fifteen tons of chlorine purchased at 12½ cents per pound would cost $3750.00 and on this basis the city of Sacramento would seem to be saving $819.50 per year by producing its chlorine on the premises, rather than by buying it, but as already pointed out, they really should be deducting from this $819.50 a proper charge for labor, supervision, chemical control, etc.

If the municipality is willing to make an investment of capital in order to secure chlorine at the minimum cost, it would seem that the logical thing for them to do would be to invest in 18 one-tone chlorine containers, which the chlorine manufacturer would be glad to furnish for $3600 ($200 each) and which containers the chlorine manufacturer would be glad to take off their hands at any time at the full purchase price. The annual charge against these 18 one-ton containers would, therefore, be 5 per cent interest plus 1 per cent insurance, or $216.

City Is Losing

With these 18 one-ton containers available for the storage of liquid chlorine, the chlorine manufacturer could, and would be glad to, supply chlorine in multi-unit tank cars at a price not to exceed 6 cents per pound f.o.b. Sacramento, instead of 12½ cents per pound, the price charged for chlorine in 150-pound cylinders, or the 15-ton annual requirements for the sum of $1800. The cost of taking the 15 full containers off of a multi-unit tank car and replacing them with 15 empty ones once a year would be almost negligible; the three extra one-ton containers would be sufficient to take care of the needs of the municipality while a new supply was en route.

Adding the purchase price of 15 tons of chlorine in one-ton containers ($1800) to interest and insurance charges of $216, we arrive at a total cost for purchasing chlorine of $2016 annually, as against an operating charge for the production of home made chlorine of $2830.50, which means that the City of Sacramento is sustaining an annual loss of $814.50 by manufacturing chlorine on the premises, rather than by purchasing in one-ton containers.

All the foregoing statements have been predicated on the assumption that the figures given by the operating staff at Sacramento are entirely correct. However, these figures are somewhat inconsistent, and therefore, open to considerable question.

If an electrolytic cell producing chlorine could operate at 100 per cent current efficiency, then 342 ampere hours would produce 1 pound of chlorine.

Over All Efficiency 63.2%

The cells installed at Sacramento are designed for 600 amps. and would, therefore, at 100 per cent current efficiency, produce 42.1 pounds of chlorine daily, or the 6 cells would produce 252.6 pounds of chlorine daily. It is stated in *Engineering News-Record* that the 6 electrolytic cells installed will produce 228 pounds of chlorine daily; consequently, it must be assumed that the cells operate at a current efficiency of 90.3 per cent.

Figuring back from this same current efficiency of 90.3 per cent, and daily production of 228 pounds of chlorine, and 2½ KWH per pound of chlorine produced, the over all efficiency of the motor generator set must be 63.2 per cent, which figure will be used in subsequent calculations herein.

At the time the Sacramento plant was inspected, water was being filtered at the rate of 32 million gallons per 24 hours, and was said to be dosed with chlorine at the rate of one-half part per million, or at the rate of 132.8 pounds of chlorine per 24 hours. At the same time the electrolytic cell installation was operating at 600 amps. 25 volts, and was, therefore, if we take the figures of the operating department as being correct, producing 228 pounds of chlorine daily.

"Unbelievably High Dosage"

Two hundred and twenty-eight pounds of chlorine daily will dose 32 million gallons of water at the rate of .856 parts per million and not at the rate of ½ part per million. A dosage of .856 parts per million is an almost unbelievably high dosage, and certainly not a dosage which one would expect to be applied to raw water to be filtered and again chlorinated after filtration, as is the practice at Sacramento.

If we assume that raw water is being dosed at the rate of ½ part per million, then the daily chlorine production was only 132.8 pounds instead of 228 pounds and the current efficiency of the cells was only 52.6 per cent. If we assume that the dosage at the time of inspection was actually ½ part per million and that the current efficiency was 52.5 per cent, the power required to produce 1 pound of chlorine was 4.29 KWH and not 2.5 KWH, a difference of 1.79 KWH which at 8½ mills amounts to 1.52 cents per pound of chlorine produced, and makes the total cost of producing home made chlorine 10.956 cents, without charge for labor, supervision, etc.

Accounting Criticized

In conclusion, the figures given by the operating department at Sacramento do not check—the statements regarding cost of production given by Mr. Jenks are unsupported and consequently must be taken as his opinion rather than as a fact—so the plant may properly be criticized for having no accurate accounting system. Furthermore, it seems a fact that Sacramento could buy 15 tons of chlorine per year more cheaply than it can be produced "home made," even taking the more optimistic of the non-checking statements given by the operating department at the filter plant as the basis of calculation.

Again, if liquid chlorine were purchased there would be no possibility of capital loss through obsolescence for the chlorine cylinders could be turned into cash at any time, whereas, due to advances in the art of treating water, the present electrolytic plant may have to be scrapped at any time and the loss taken by the City of Sacramento.

Beverly Hills Water Safe

Beverly Hills, California, citizens have complained so much of the water that the chamber of commerce has sent out a report to all consumers explaining the situation. This report states that the water is entirely free from harmful bacteria and safe for domestic use, and says that the objectionable odor and taste are due to the presence of hydrogen sulphide and its resultants, which though disagreeable are harmless.

The cure for the situation lies in the following:

1. Additional water supply.
2. Filtration—probably mechanical sand filters.
3. Additional reservoirs.

KENNEDY

Hydrants and Valves

fully proven in municipal service

You can be sure of permanently satisfactory operation by specifying Kennedy Valves and Hydrants. They are time-tried and have proven their goodness in numerous important installations which have demanded the best sort of service.

The high pressure systems of New York and Boston include more than 6,000 Kennedy Gate Valves. Kennedy Hydraulically-operated Gate Valves form the main valve equipment of the Mayfair Pumping Station in Chicago, and many Kennedys of various types and sizes are in use in other pumping stations in Chicago, St. Louis, New York, Brooklyn, Cincinnati, and other cities throughout the country.

Kennedy has built over 10,000 Fire Hydrants for New York and St. Louis alone, and Chicago, Detroit, Jersey City, and Cincinnati are only a few of the many cities that are using Kennedy Hydrants with complete satisfaction.

These cities have tested Kennedy equipment, and their experience with Kennedy reliability is evidenced by numerous repeat orders. No matter what service requirements or money outlay may be involved in your valve needs, you will be fully protected by the Kennedy experience of 47 years and our guarantee of performance.

Pacific Coast States Boast Lowest Typhoid Death Rate

New Water Supplies, as well as Filtration and Chlorination, Spell Doom of the Germ

THE Pacific and Rocky Mountain states, together with the East North Central States, have the lowest typhoid death rate of any of the geographic sections, according to figures compiled by the American Medical Association in 1925, with a score of 2.22 per 100,000 in cities of 100,000 or more. (Table 1).

TABLE 1

TYPHOID DEATH RATES IN THE VARIOUS GEOGRAPHIC DIVISIONS IN 1925

Cities of more than 100,000 population in	Population	Typhoid Deaths	Rate
New England states	2,308,266	56	2.42
Middle Atlantic states	11,279,063	333	2.95
South Atlantic states	1,354,748	110	8.12
East North Central states	7,344,968	163	2.22
East South Central states	570,012	92	16.14
West North Central states	2,072,228	64	3.09
West South Central states	717,491	103	14.36
Mountain and Pacific states	3,235,255	72	2.22

The Journal of the American Medical Association published in March, 1926, its fourteenth annual survey of typhoid fever mortality in the seventy-seven cities of the United States with more than 100,000 population in 1925. These cities have been grouped according to the recognized geographic divisions of the U. S. census bureau. In the Pacific-Rocky Mountain section ten cities (Table 2) are included; of these

*Rate calculated on population figures furnished by the health department.
†December 1, 1924, to November 30, 1925.
‡Rate calculated on figures for population in 1924 with same annual increment added as 1922-1923 and 1923-1924.

San Diego is reported for the first time. Each of these ten showed less typhoid in 1925 than in 1924. The decrease was especially noticeable in Los Angeles and Portland. All the five-year averages, too, with one exception (Tacoma) show a reduction from each preceding five-year record. The five-year averages show a decided improvement all over the country, though for every section except the Pacific and Mountain states the record was higher for 1925 than it had been in 1924. It seems to be true that for most of the country 1925, like 1921 and 1913, was what might be termed a "typhoid year."

Cause for Good Record

To the introduction of new water supplies and the improvement of both new and old by means of sanitary protection, filtration and chlorination the heavy reduction and in many places the virtual disappearance of typhoid fever is largely due. No longer than 30 years ago typhoid death rates of 20 to 100 per 100,000 were common, with rates in bad years in the most afflicted cities running much higher. In 1925 there were two cities of more than 100,000 population (Lowell, Mass. and Scranton, Pa.) with no death from typhoid, and there were twenty-eight other cities with a rate of less than 2 per 100,000. Of these, five were in the Pacific-Mountain section.

Public water supplies not only substitute safe for unsafe drinking water, but also make possible sanitary sewers and with them the abolition of the dangerous privy and cesspool. With the privy the typhoid fly also disappears. The great reduction in typhoid fever in the United States registration area has been largely due to the measures taken in the urban areas. Reduction in rural typhoid has been less satisfactory.

Where Germs Breed

Typhoid fever organisms, so far as known, breed only in the bodies of infected persons, whence they are discharged. Unless these discharged organisms get back into the human body the line is broken. Water is one of the carriers from the infected person back to the second individual. Milk, other food-stuffs, and direct contact are the other media of infection, but they are not the concern of the water works official except as they confuse the question as to cause and its elimination. The term "infected persons" comprises all persons ill with typhoid fever, a considerable portion of recent convalescents, and about 3 per cent of all persons who have previously had typhoid fever.

All water, whether taken from surface or underground sources, has at some time since its precipitation been in contact with the surface of the earth, and has consequently been more or less exposed to pollution with the intestinal discharges of persons and lower animals upon its catchment area. Between the sources of pollution and the ultimate destination of the water are numerous agencies operating to reduce the numbers of typhoid bacilli and other intestinal bacteria which may reach the consumer. These safeguards comprise all the agencies which tend to destroy typhoid bacilli and other intestinal bacteria in the natural and artificial processes of sewage disposal and water purification.

Control of Water Supplies

A sharply defined epidemic of typhoid fever affords the best opportunity to determine definitely the effect of a water supply in the causation of this infection. This is so primarily because the very distinctness and sudden development of an epidemic argue the operation of a single, distinct and unusual cause, the spread of the infection from a single source, since it is essentially improbable that two or more unusual sources of infection should have developed independently and simultaneously.

Control and supervision of water supplies by health departments have been a gradual development of the past thirty years. In earlier times cities found little difficulty in securing supplies from sparsely populated water sheds or from sources which were not grossly polluted. With the rapid growth in population and an accumulation of knowledge of water borne diseases, the ever-growing menace to many municipal supplies began to be realized. Two protective courses were possible: better protection of the catchment areas, or nullification of the pollution by appropriate treatment of the water before delivery to the consumer.

The causative relation of polluted water to the toll in deaths was clearly established by the work of experiment stations. The reduction in typhoid deaths effected by substituting a filtered for a polluted surface supply was demonstrated in many American cities in the first decade of the twentieth century. Yet many cities refused to accept the lesson, and in such cases the state had to provide laws. The interest and activity of the Federal Government has been a large factor in encouraging state control of water supplies. The United States Public Health Service found that the most effective way to prevent the spread of water borne diseases was to assist in developing and perfecting state and local machinery for this purpose. By detailing or lending sanitary engineers to states, the Service has been instrumental in securing the establishment of a sanitary engineering division in more than a dozen states. Health departments of 43 states now have divisions of sanitary engineering, though many of these are as yet only "one man" divisions.

50 Years of Progress

Until 1870 there were no water filtration plants in the United States as the term is now understood, but some of

the surface supplies then in use were passed through so-called filters or strainers of gravel, charcoal or sponge. In 1925, according to figures of the American Water Works Association, there were about 587 rapid and about 47 slow sand filters in use, with a total capacity of approximately 5,000,000,000 gallons per day.

Chlorination dates from 1908. It is now used on nearly all surface supplies, whether filtered or not. In 1924* over 3,750,000,000 gallons per day were being treated in more than 3000 cities and towns of the United States. It is estimated that 70 per cent of the population of North America are drinking water treated with liquid chlorine. In all there are now 6000 installations of chlorinating equipment operating in the United States.

*Water Works Practice, chapter on Chlorination.

Plans $5,000,000 System

Santiago, Cuba, is planning the installation of a new waterworks system which, when complete, will cost approximately $5,000,000, according to a statement made by Dr. Elwood Mead, commissioner of reclamation. Dr. Mead has just returned from Cuba, where he went to advise the Cuban government with regard to this installation.

According to Dr. Mead, Santiago now has a population of 80,000 and, with the very rapid agricultural development of Cuba, it is destined to become a large city. It has a fine harbor and is the terminus of the railroad from Havana. The present water supply, however, is wholly inadequate. The Cuban government is going ahead with the proposed waterworks for Santiago, Dr. Mead stated, and specifications for the project are now being prepared.

Water Company Extends Lines

Increased demand upon the Hoquiam (Washington) water supply has made better facilities necessary, and to meet this demand the Hoquiam Water Company announces that work is well under way in the replacement of 2000 feet of 10-inch cast iron pipe by 16-inch pipe. Extension of the city mains across the Hoquiam river into the Woodlawn addition is nearly completed.

San Bernardino Builds Dam

A huge flood control and water conservation reservoir is being built by the San Bernardino, California, board of water commissioners on city-owned land. The dam will be 700 feet long and will have a capacity of approximately 12,000,000 gallons of water.

SEWAGE DISPOSAL

El Segundo, Calif., Uses Asphalt for Sewer Joints with Success

By ADOLF H. KOEBIG, Jr.

FOR many years it has been quite a problem in the construction of sewers to find a joint that would do away with the infiltration of tree roots through the pores of the cement joints. Sanitary engineers throughout the country have been experimenting to overcome this feature by making the joints of cement more dense but invariably it rested with the mechanical workmanship of the contractor whether or not the joints could be made dense enough to overcome this difficulty.

For a long time the firm of Koebig & Koebig, as well as other engineers, have tried to introduce the use of an asphalt joint to overcome this problem. Mr. Ferguson, the inventor of hollow tile block for lining purposes in the construction of sewers, has advocated the asphalt joint to be applied in its cold state.

At the left a workman is shown "pouring a joint." Hot asphalt is the sealing medium being used, selected by the engineers for the reasons set forth in the accompanying article. On the right: line-construction work in a sandhill section.

Tried at El Segundo

In the designing and construction of the El Segundo, California, sanitary sewer trunk line system, serving the city, it was possible to introduce the asphalt joint, applied in a hot state, as the City of El Segundo is the location of a large refinery of the Standard Oil Company and the suggestion was looked upon favorably. The poured asphalt joint was adopted for the entire work, being the first sewer known in this territory, or perhaps throughout the entire western territory, that really has applied the use of the asphalt joint for sewer construction.

The first contract for installation was for approximately twenty-four thousand lineal feet of vitrified clay pipe, varying in diameter from eight inches to eighteen inches; the construction of a main pumping station and two ejector stations, and the driving of three tunnels, the total length of which is twenty-five hundred feet.

It was found in experimental work that the asphalt joint adhered equally as well on either cement or vitrified glazed pipe.

Topography a Problem

The peculiar topography of El Segundo necessitated the construction of two ejector pumping stations at the southerly end of the system. These plants will serve areas too low to be reached with a gravity line, and discharge into the main trunk line at the up-stream end, from where a gravity flow is provided to the main pump station located in the northwest part of the city. In this station are installed two four-inch centrifugal pumps, operating under a head of twenty feet, and discharging into the Los Angeles Belleview outfall sewer.

Adequate stand-by service has been provided to insure continuous operation of all mechanical equipment. The pumps are electrically operated, and, in an emergency, may be supplied with energy furnished by a gas-engine-driven generator, located in the same plant.

To facilitate the construction of the lateral system, the city was divided into districts. The contract was awarded for the installation of approximately twenty thousand lineal feet of six-inch and eight-inch vitrified clay pipe with asphalt joints and plans prepared for a lateral system to serve the remainder of the residence portion of the city.

At this time we have no definite detail cost data on the use of the asphalt joint, but I may say that the cost of the entire joint, labor and material, will only exceed the cost of the cement joint about 33 1-3 per cent, which is very small when you consider the results obtained.

Some of the advantages in the use of the asphalt joints are as follows:

1. The density and nature of the

Here are the advantages in the use of asphalt for sewer joints, as Mr. Koebig sees it:

1. The density and nature of the asphalt joint prevents the growth of roots in the sewer.

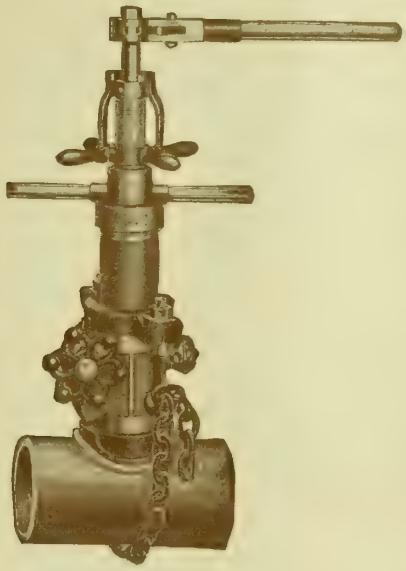
2. Any settlement occurring in the alignment of the sewer is taken up by the elasticity of the asphalt joint.

3. Industrial wastes and acids do not affect asphalt joints.

4. A defective join is always easily detected.

5. The greatest adhesion is obtained by pouring the joint while the asphalt is in a heated liquid state.

A TRIED AND TRUE FRIEND

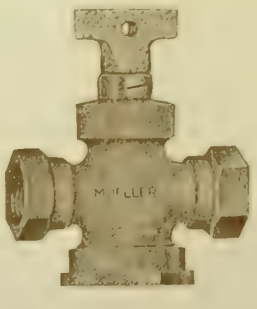


YEARS have proved its faithfulness on all kinds of jobs and all water workmen who use Mueller B Tapping Machine know it as a friend indeed.

When it comes to making a tap ½″ to 1″ and inserting a corporation stop under pressure, no device has yet been offered that does it as easily, quickly and economically as the Mueller machine.

And Mueller corporation and curb stops work hand in hand with Mueller machines—with just as fine a reputation for honest service. It does not make any difference what pattern curb stop you use—Solid Key, Patent Cap, Minneapolis Top, "H" Pattern or what not—Mueller supplies it.

Calking tools, branch connections, goose necks, service boxes, repair lids, bearing the name Mueller are a guarantee of good and satisfactory service.



MUELLER CO.

asphalt joint prevents the growth of roots in the sewer, which is one of the greatest nuisances in the maintenance of the sanitary sewer system.

2. Any settlement occurring in the alignment of the sewer is taken up by the elasticity of the asphalt joint.

3. Industrial wastes and acids do not affect the asphalt joints.

4. In the use of the asphalt joint a defective joint is always easily detected as the asphalt, being in a fluid state, will run into the crevices of the defect.

5. The greatest adhesion is obtained by pouring the joint while the asphalt is in a heated liquid state.

Gaining in Favor

There is no doubt in the mind of the writer that asphalt joints will be used more and more each year in preference to cement joints, especially in the East where there is another advantage to be gained in the handling of the asphalt during freezing weather.

The engineers dealing with sanitary sewers are adopting the use of asphalt joints more and more each day. On account of the elasticity of a good grade of asphalt, and the fact that it is not brittle, it is looked upon very favorably in earthquake territories, especially in sections of California where earthquakes have occurred.

The sewer system of El Segundo was designed by the city engineer, R. T. Hutchins of El Segundo, and Koebig & Koebig, consulting engineers, 821 Title Insurance Building, Los Angeles.

Discuss Sewage Problems

The American Society of Civil Engineers turned its regular quarterly fall meeting into an annual convention at Philadelphia, which lasted six days, from October 4 to 9 inclusive. The sanitary engineering division at its Wednesday meeting presented 150-year reviews of the progress in seven fields of sanitary engineering. George W. Fuller read a paper on waterworks; Harrison P. Eddy discussed sewerage; Dr. George T. Palmer dealt with ventilation; and S. H. McCrory talked of land drainage.

The Thursday morning session was given over to a symposium on industrial waste disposal, devoted chiefly to current phases of the subject as regards four classes of waste. The four specific wastes discussed in papers were as follows: oil refinery, Robert Spurr Weston; coal mine drainage, Andrew B. Crichton; pulp and paper mill wastes, George K. Spence; tannery wastes, Wilhelm Howalt. The symposium stressed the growing co-operation between state authorities and the various waste-producing agencies in the control of pollution.

Lake Michigan Sanitation Congress in Annual Meeting

The Lake Michigan Sanitation Congress held its third annual meeting at Racine, Wisconsin, on September 24 and 25 with about 100 present. The purpose of the congress is an exchange of information between officials and those working on the water and sewage problems of the lake cities in Michigan, Illinois, Indiana and Wisconsin. There was a three-session program, with 25 speakers, and on the second afternoon the delegates inspected the Milwaukee sewage works.

"The Relation of Industrial Waste to Sewage Treatment" was the subject of a paper read by C. M. Baker, state sanitary engineer, in which he discussed specifically the co-operative work between paper mills and canning factories and the state board of health in working out solutions of the waste problems. Recovery of $28,000 worth of wood fiber annually at a 50-ton sulphite mill costs $15,000 for installation and removes the equivalent of the sewage of 150,000 people.

H. P. Ramey, assistant chief engineer, Sanitary District of Chicago, outlined the progress made by the district in meeting the requirements of the War Department in accordance with the provision of a grant of 8,500 second feet of diversion water from Lake Michigan. More than $45,000,000 has been spent on sewage disposal and the program demands about $12,000,000 annually. The North Side activated-sludge plant, the largest plant of its kind in the world, planned to care for 800,000 people, is three-fourths complete, and cost $21,000,000. The West Side plant, for 1,600,000 people, has been started. At least one-third of the plant must be completed by 1928.

Milwaukee's Plant

T. C. Hatton, chief engineer, Milwaukee Sewage Commission, reported that the activated-sludge plant of that city is treating 45 m.g.d. The sludge is filtered, dried and sold at an average net return of $13.48 per ton. Seventy per cent is sold to fertilizer companies, 20 per cent to golf courses, and 10 per cent for city lawns. Mr. Hatton states that there is a ready market for all that Indianapolis and Chicago can produce.

Other points brought out at the sessions were as follows: That analyses show that a safe lake water cannot be obtained nearer than from seven to eleven miles out; that filtration is coming for Chicago, $100,000 having been appropriated for experiments; that Racine has a filter ready for operation within two months' time; that filters alone without elimination from the lake of sewage from the cities of Northern Indiana will not produce a satisfactory water free from phenol tastes; and that the analyses of more than 30,000 samples of water taken in three years show that Waukegan distributes the least safe water of any city from Waukegan to Gary, because of insufficient chlorine.

Officers of the congress were re-elected as follows: H. W. Lee, president; J. A. Hendricks, secretary.

Cement Concrete Pipe Tests Are Made at Selma, Calif.

Is One of a Series Being Conducted by Association; Report Will Be Issued When All Are Completed.

The California Associated Concrete Pipe Manufacturers held their fall convention at Fresno on October 9. The program was especially prepared for engineers and others who wished to know more about concrete pipe manufacture, the association presenting a series of exhibits and public tests on irrigation, sewer and culvert pipes, to demonstrate the range of uses to which these products are adaptable.

Hydrostatic tests were run on single sections and laid lines of concrete pipe to show their resistance to internal pressures when used as conduits for carrying water under pressure heads. The imperviousness and tensile strength of non-reinforced and reinforced concrete pipe as manufactured by various methods was brought out by the hydrostatic tests.

Crushing tests were run on single sections of both plain and reinforced pipe to show their resistance to external loads. The materials, gradings, proportions, and methods of manufacture were exhibited for each specimen tested.

The tests were held in the yards of the I. Jourdan Company at Selma, California, twelve miles South of Fresno, where a modern manufacturing plant is in operation enabling the visitors to view the manufacturing process for "machine made" concrete pipe in all its details.

Manufacturers of irrigation appliances exhibited their equipment and explained to engineers their uses in irrigation design.

The following is a condensed outline of the tests that were made:

1. *Irrigation Pipe*: Hydrostatic tests on ten laid lines of 10 and 12-inch concrete pipe showing types of reinforcing two types of joints and ten tests on individual sections of irrigation pipe.

2. *Sewer Pipe*: Hydrostatic tests on eight laid lines of concrete sewer pipe as used in sanitary sewers at Fresno and other cities. Crushing tests were run on individual joints of this pipe.

3. *Culvert Pipe: Crushing tests* on four types of plain and reinforced concrete culvert pipe of 12 to 36 inches in diameter.

The association announced that a comprehensive report on the tests would be made after several other tests, planned for different localities in the state, were completed.

Jackson Is Vice President of Merged Water Companies

Deal by Which Fresno, Bakersfield, Visalia and Chico Properties Pass to New Hands

Contsummating negotiations extending over a period of several weeks, the Federal Water Service Company of New York on Oct. 18 took over control of the Fresno City Water Corporation, Fresno, Calif., a $2,500,000 distributing system. The consideration was not given.

The old directorate of the company, headed by A. G. Wishon, president, resigned in a body and an entirely new board headed by E. T. Chenery of New York, president of the purchasing company, was elected.

C. B. Jackson, for many years general manager of the Fresno company, was elected vice-president and general manager and will be general manager of recently acquired properties at Bakersfield, ViVsalia and Chico, it was announced. E. B. Walthall, former assistant general manager of the San Joaquin Light and Power Corporation here, was elected vice-president and assistant secretary and assistant treasurer.

Other officers and directors are A. W. Cuddeback, New York, vice-president; Walter A. Culin, New York, secretary-treasurer; E. Pillsbury and J. G. Eliot, both of San Francisco, directors.

Until its sale control of the company was held by Western Power Company of New York, which acquired control in December, 1924, at the time Western Power took over San Joaquin Power.

New Fire Hydrant Head

The James Jones Company, manufacturers of brass goods such as used by municipal and public service corporations, have recently added to their line a fire hydrant head with double outlet cast in bronze. The valve seats and stuffing boxes are cast in as part of the hydrant. The Jones head can be used with either cast iron or standard pipe as a raiser. It is very simple in construction and can be taken apart for repair and put together again with an ordinary wrench, thus obviating the necessity for special tools.

You *Name the* Load
We *Make the* Pipe!

SINCE concrete pipe (as made by Bent) came into its own, engineers question no longer its striking advantages for a great variety of uses. *But*—a concrete pipe installation is either a mediocre or an eminently superior job of work, depending upon who fulfilled the contract.

Many trade names have become hall-marks of tradition, that serve as an unerring guide to discriminating buyers. Today the name "BENT" on a joint of Concrete Pipe marks it as a strictly finely made product. The same care and skill is exercised in its manufacture, and in the laying of the line, as though every future contract depended on *that* job meeting the fullest requirements of specifications—*and more.*

Let us give you a "concrete" demonstration of what we mean by "Bent" Service.

YEOMANS

Centrifugal Sewage Pumps

HEAVY duty slow speed direct connected Centrifugal Pumps for handling crude sewage or settling tank effluent and sludge in municipal sewerage systems. A wide yoke thrust bearing permits raising top plate of pump without disturbing working parts. Liberal water passages insure against clogging.

Also built in horizontal design.

Complete installations for municipalities designed, built and erected.

With the Exhibitors

(*Continued from Page 60*)

AMERICAN CAST IRON PIPE COMPANY will feature their new type Mono Cast Centrifugal Pipe J. J. Swenson, Pacific Coast manager and W. R. Blair, of the San Francisco office, will have charge of the exhibit and will explain the process of manufacture and special advantages of this type of pipe.

ART CONCRETE WORKS, Pasadena, California. Concrete water meter boxes in eight sizes, and service or valve boxes. Frank M. Brooks, of the Pasadena office, and H. L. Brooks, of the Oakland office, will have charge of the exhibit.

DEARBORN CHEMICAL COMPANY, Los Angeles, will feature their No-Ox-Id Rust Preventive. A. G. Burns and H. G. Smock, of the Los Angeles office will be in attendance.

DE LAVAL STEAM TURBINE COMPANY, Trenton, New Jersey, will have an exhibit of centrifugal pumps, worm gears, steam turbines, and flexible couplings. L. A. Safford, district manager, will be at the head of the exhibit, and he will be ably assisted by C. H. Johnston, from the Los Angeles office, E. L. McKie, of the San Diego office, and C. P. Markley, of the San Francisco branch.

EVERLASTING PAINT AND SALES COMPANY will have a full line of their products on exhibition, including Luminite, Concrete damp proofing, protective coatings for metals and woods, Hunt patent process for curing concrete, etc. Logan Thomas, of the Los Angeles office, will be in charge of the exhibit.

FORNI MANUFACTURING CO., Oakland, California, will show samples of the Forni concrete meter box. George & N. Forni will be in charge.

FAIRBANKS, MORSE & COMPANY will feature in their exhibit their Horizontal ball-bearing centrifugal pump, direct connected with the Fairbanks-Morse ballbearing motor. They will also show a bronze impeller for the Woods sewage pump.

OTHER EXHIBITORS will be Chicago Bridge & Iron Co., Steel Tank & Pipe Co., Pittsburgh-Des Moines Steel Co., A. N. Byers Co., General Electric Co., National Iron Works, Machinery Pipe & Supply Company, Baker Iron Works, Cement Gun Construction Co., Crane Co.

Purchases Three Water Systems

San Gabriel Valley Water Company has been authorized by the California Railroad Commission to purchase from the Huntington Land and Improvement Company, for the sum of $300,000, the water systems known as the Oak Knoll, Patton and Rosemead System, and to issue its promissory note in that amount payable on or before five years from date with interest at six per cent per annum, payable quarterly. The same utility, having applied to the Railroad Commission for permission to increase its rates, and the Commission after investigation having determined that the present rates are inadequate, has authorized that company to place in effect a new schedule of rates September 30, 1926, as follows: Domestic use, monthly minimum charges: for ⅝-inch meter, $1.25; ¾-inch, $1.75; 1-inch, $2.50; 1½-inch, $4.50; 2-inch, $6.00; 3-inch, $12.00; 4-inch, $20.00; 6-inch, $35.00. Monthly quantity charges: 500 cubic feet or less, per 100 cu. ft., $0.25; 500 to 5000 cu. ft., $0.20; over 5000 cu. ft., $0.12. Irrigation Use—monthly minimum charges: Same as for domestic use; monthly quantity charge, $0.08 per 100 cubic feet.

This City Claims Water Record

Every man, woman, and child in Sacramento, California, theoretically at least, used an average of 312 gallons of water daily during the months of June, July and August, according to figures recently compiled by City Engineer Allan J. Wagner. The city filtration plant serves approximately 85 per cent of Sacramento's population, the remaining 15 per cent receiving water from the Oak Park and other private plants.

The records show a total of 2,545,900,000 gallons pumped by the filtration plant into the city mains, divided as follows: June, 852,200,000; July, 870,100,000; August, 823,600,000. Based on a cost of 7 cents per 1000 gallons delivered to the consumer, the per capita cost for the summer months was 2.2 cents daily. Wagner's conclusions are that Sacramento uses more water and gets it more cheaply than any city in the country.

Buys New Water Tract

Anticipating domestic water supply requirements for years to come, the commissioners of Santa Monica, California, have purchased fifteen water-bearing lots. According to Public Works Commissioner John A. Morton, more than double Santa Monica's present domestic water supply can be developed in wells on this property, known to hold underlying water-bearing sands of heavy underground reservoir capacity.

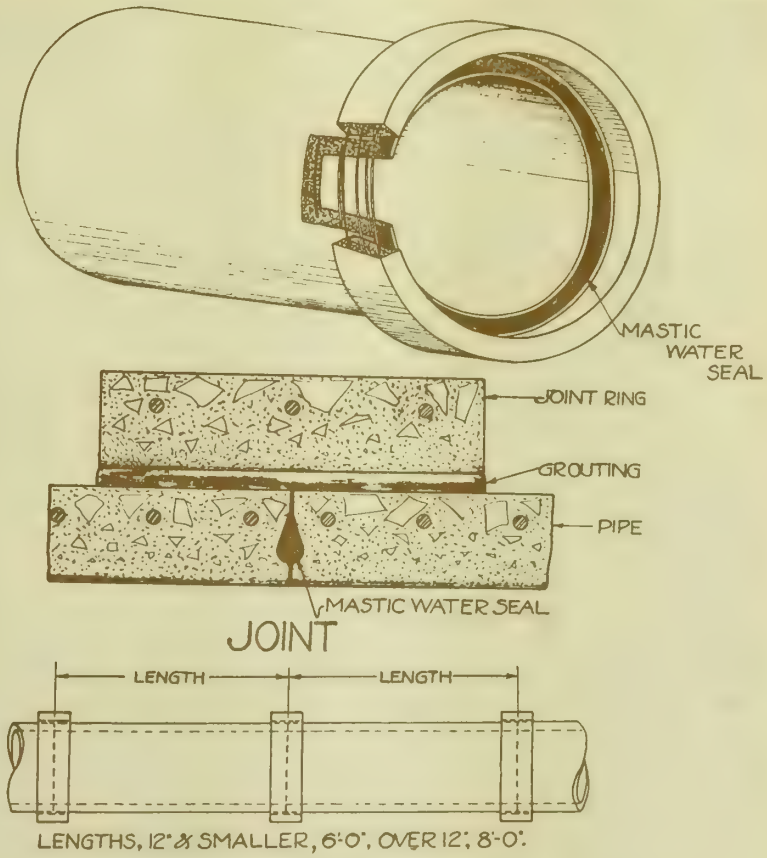
More than 500 inches of water is the yield of three municipal wells on the five adjoining lots owned by the city, and Commissioner Morton says five more wells should be sunk on the newly acquired land to tap water-bearing strata of tremendous yield. Three of these wells will be sunk this winter, the commissioner stated.

Redlands Will Double System

Redlands, California, expects soon to have one of the finest million-dollar domestic water systems in the state, from which about 1000 inches continuous flow can be provided. Work of doubling the water system with the funds from the $500,000 bond issue recently voted is now under way, with George Hinckley, city engineer, in charge. Redlands purchased from Old Town ranchers the 400 inches flow from Mill Creek which they owned, for about $400,000, it is stated. The gravity water from Mill Creek can be run on a level to the higher sections of the city. The city is to build a great pipe line to the hill sections to carry this water, and work on a $30,000 filter plant is now under way.

Centrifugal Reinforced Concrete Pipe

Spun by the Hume Process



Introduced Now in the West for High Pressure Pipe

This pipe is impervious to soil corrosion and free from leakage at high pressures. Tests show unit tensile strength in excess of 400 pounds per square inch, which is double that of the best concrete by old methods.

We are prepared to furnish and lay Hume Concrete Pressure Lines. Prices upon application.

WESTERN BUYERS' GUIDE

OF WATERWORKS AND SEWAGE DISPOSAL EQUIPMENT

WESTERN WATERWORKS presents the following Buyers' Guide to the leading Western sources for waterworks equipment and auxiliary supplies. Purchasing departments, engineers and all others who do ordering or specifying will find this department of great practical value, listing as it does the most representative lines handled by western manufacturers and distributors. The listings herewith are not, as yet, entirely complete but will become more so with future issues of the publication. To this end, the publishers bespeak the active co-operation of the companies whose products are included below. Send all corrections or additional listings by mail and at the earliest possible before press date.

The Vale Irrigation Project

(*Continued from Page 30*)

district to be used by the Vale project results from early overestimates of the irrigable area in the Warmsprings district. Seepage encroachments and refractory alkaline soils have reduced the amount of tillable lands in this district until at the present time about one-third of the original area of 37,000 acres classed as irrigable is capable of producing crops.

This reduction in area has reduced the resources of the district to such an extent that it is incapable of financing a drainage program. By the terms of the pending contract for purchase of the surplus Warmsprings Reservoir capacity, the United States will divert from $150,000 to $200,000 of such purchase money to provide drainage for the district lands, and without further consideration the Warmsprings district drains will also carry off drainage waters from the high-lying Vale project lands.

TOTAL COST $3,590,000

The total cost of the project is estimated at $3,590,000. Of this amount about two-thirds is required for the diversion weir and the main canal and approximately one-fifth for storage. The remainder of the estimated cost is required for laterals and drainage.

By means of a supplemental contract with the Warmsprings irrigation district it has been arranged that this district shall utilize the drainage and return flow from the Vale project lands to the greatest extent possible, with the Vale project receiving Warmsprings Reservoir storage in equal amount in exchange.

The total area commanded by the canals of the Vale project, not including lands now having a full water supply, is 36,000 acres. Soil surveys and a land classification indicate 32,095 acres thereof irrigable, for which 2,776 acres now receive a partial water supply from various sources.

With appropriate allowances for rights of way and equivalent areas of full water right in lieu of the area now receiving a partial supply, the net irrigable area would be equivalent to 28,350 acres receiving a full water supply.

This Firm Features Promptness

The De Laval Steam Turbine Company is making a record for prompt service. The Los Angeles office recently received a telephone message from Allan P. Rowe, engineer of the office of J. B. Lippincott, asking for a complete set of repair parts as soon as possible. Within thirty minutes the parts had been delivered.

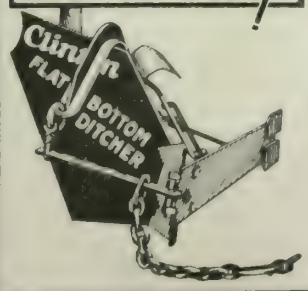
Make Your Ditch a Natural Water Course



Here are— 5 Advantages: you'll appreciate in this tool:

1. It builds a ditch which carries more water than a "V" ditch, depth and fall being equal.
2. The "off" horse walks on the flat ditch bottom instead of on the slope.
3. Silt fills this type of ditch more slowly and there is less overflow.
4. Erosion is minimized in the flat bottom ditch.
5. It can be cleaned out with greater ease for it keeps its shape.

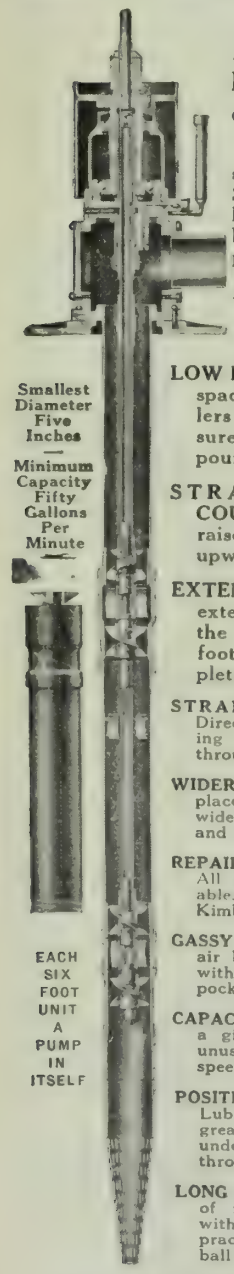
IT'S NOT in the HEAD IT'S IN THE PUMP!!!

Mister Dealer
Mister Pump User



Here is news! Interesting News! For both of you.

Satisfaction assured to both the Seller and the Buyer. The Kimball story is complete—read it!

ADAPTABILITY. Large capacity from small well.

LOW PRESSURES. The spacing of the impellers reduces the pressure to less than three pounds at any part.

STRAIGHT WATER COURSE. Water is raised in a straight upward course.

EXTENDABILITY. All extensions made from the top. Each six-foot section a complete pump.

STRAIN DISTRIBUTION. Direct flow allows spacing of impellers evenly throughout the shaft.

WIDER RANGE. Semi-displacement permits a wider range of speed and capacity.

REPAIRS EASILY MADE. All parts interchangeable. Don't return the Kimball to the factory.

GASSY WELLS. Gas and air bubbles are raised with the water — no pockets to collect either.

CAPACITY. Greater from a given size well with unusually slow rotative speeds.

POSITIVE LUBRICATION. Lubricated with soft grease from the inside under high pressure, through hollow shaft.

LONG LIFE. Only the best of materials, combined with skilled engineering practices, go into Kimball Pumps.

FRANK J. KIMBALL CO.
1857 E. 15th St. Los Angeles, Calif.

Looking Backward—(*Continued from Page 13*)

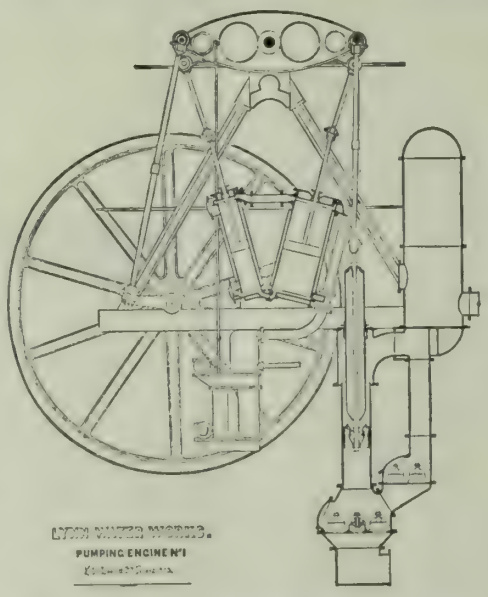
The famous Tea-water pump, from Costello's History of the New York Fire Department.

The fire box was made of wrought iron plates about 3 feet square. Most of them were imported from England. The flues were vertical and were made of cast iron through which the water passed. Steam pressure was from 2½ to 4 pounds per square inch. These wooden boilers rotted out in about seven years and were replaced by cast iron boilers.

THE INSPECTOR'S REPORT

Inspector Thos. P. Cope, Esq., took the stage from Philadelphia in the morning of July 3, 1800, and arrived at the Soho Works (North of Newark, N. J.) at noon on the next day, visiting the machine shops of Nicholas J. Roosevelt (capitalist and owner of the works) to inspect the engines being built for the Philadelphia Water Works.

The difficulties of making two boilers, one a wooden one, like that which was put in at Philadelphia, the other of sheet iron, on Bolton and Watts construction. The fly wheel is driven by a sun and planet motion and the shaft works three small pumps with common cranks."

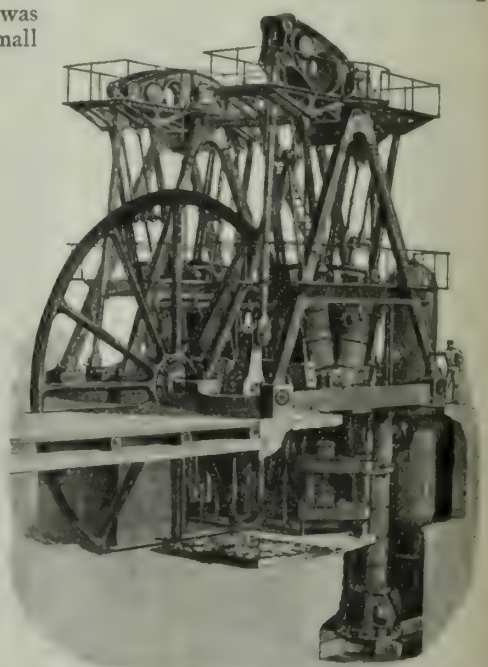


Lynn Water Works compound pumping engine, 1874. From Transactions Franklin Institute

In 1803 a second engine was purchased for $8,000, which allowed the eight horses and horse driven pumps to be retired. Each of these steam engines was 18 H.P., a size which is extremely small according to our present day ideas of power but which was the average of the engines of the day. This water system was in use until the Municipal water works went into operation in 1842.

The engines for the Philadelphia Water Works were manufactured by Nicholas Roosevelt during 1801 at his plant near Newark, N. J. There were two engines, one of 32-inch diameter driving an 18-inch pump, and the other 40-inch diameter driving a 17½-inch pump. The stroke of both engines was 6 feet. The lever beams, arms and shafts of the fly wheels, and even the boilers were made of wood. These wooden steam boilers were rectangular chests made of white pine plank 5 inches thick.

The boilers were 9 feet square and 15 feet long, braced on the outside with oak scantling and securely bolted together with iron rods passing through the planks.



Compound beam water works engine, from Transactions Franklin Institute, 1872

the Roosevelt engines are set forth in an interesting report of July, 1800, by the inspector from Philadelphia: "All of the large cylinders are cast in two pieces and united by copper, the joints being secured externally by a strong iron band of cast iron weighing 1,200 pounds. 7,500 pounds of cast iron were used to make the cylinders. Two men were required to bore about ¾ of an inch from the castings; one almost lives in the cylinders with a hammer in hand to keep things in order and attend to the tools; the other attends to the frame on which the cylinder rests which is moved forward by suitable machinery; the work goes on day and night. One man is also employed to grind the tools which are changed every ten minutes. I examined some and found them worn ⅛ of an inch in that time. Three tools are fixed in the boring headpiece which is firmly secured to the end of an 8-inch iron shaft which has undershot water wheel on the other end. The boring of this cylinder commenced on the 9th of April; has been going on for the last three months and will take six weeks more to finish."

The records state further that after the cylinder was bored it was found to be at least ⅜ of an inch larger diameter in its middle than it was at the ends.

A Very Old Art

As shown by the four brief histories of the development of water works for these communities, the art is very old. Hero of Alexandria in 150 B. C., showed the principle of a force feed pump being used for fire engines, but undoubtedly it must have been utilized also for forcing water for fountains and other purposes as it is reasonable to suppose that the pump shown by him at this early period required a considerable number of years to develop in order to be as effective as indicated by his contemporaneous writers. The evidence we have from the ancient philosophers of Europe of the existence of small force pumps, with only slight detail changes from Hero's pump and used for fire and other purposes, shows that these pumps were well known and no doubt were frequently employed, especially among the older communities.

For more than 100 years after the lignum-vitae pumps at Bethlehem, Pa., were made, the same general form of force pump was used, driven by water wheels and later by steam engines.

The introduction of the steam engine early in 1800 brought about a considerable change in the problem of supplying water to our organized towns and the successful commercialization of these power units is demonstrated by the increase in the number of water works in America. At the close of 1800 there were 17 water works in the United States; this doubled to 34 in 1825 and there were 100 in 1850. This had increased to 243 in 1875, after which there was a very rapid growth and 1,000 water works are recorded in 1885. In the next 10 years this had tripled and by 1925 over 10,000 water works were registered.

Effect on Civilization

There has been a tremendous effect produced by the development of these water works systems. The standard of living and of safety and health of all people so supplied has been greatly benefited thereby. Whenever any of us dwelling in cities are deprived of water in our home or place of business, through an accident of some kind, the routine of our lives is entirely upset. It would require a very considerable readjustment if, instead of just turning a faucet to procure a profuse supply of hot or cold water, it should become necessary for all of us to take this water out of a well by an old oaken bucket or a more prosaic hand pump or to carry water in pails from some spring or stream.

In appreciation of the importance and convenience of our present water supplies, we should feel grateful for the early work of the men who not only developed this art, but who worked on the early steam engines and in machine shops in which these aids to civilization were produced.

The development of water works pumps, after the early steam engines had been applied to drive them, was rapid as is the growth of most mechanical appliances. The cheaper power produced by the compound and later the triple expansion engines allowed of the development of high duty pumping stations on a new basis of efficiency and capacity.

The development of these large pumps during this period was exceedingly interesting. Practically every community of any size had a show pumping station which consisted of a structure several stories high surrounding a slow speed engine operating innumerable pumps. This monumental mechanical structure was made of polished iron and steel with considerable brass work, and it contributed much to the mechanical knowledge of the youth of the day.

The lubrication of these early pumps and engines fit in with the historical development of lubricants. The first forms were lubricated by the animal and vegetable oils and fats, there being nothing of a complicated nature in either the machinery or the lubricants, and that which was available locally was quite sufficient for the work. As the plants became more complicated greater demands were made on the lubricants.

Perfect balance of the pump runners—an oiling system eliminating the danger of sand and water in the oil tube—superiority of materials with care and skill of manufacture—aid in producing the stability and long life of

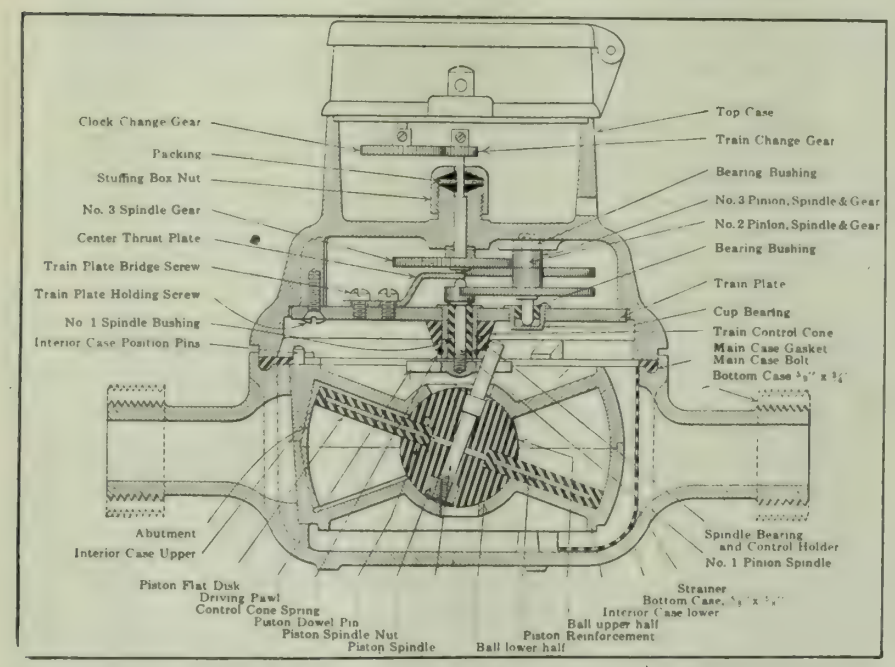
TRADE NOTES *of the* MONTH

UNIQUE TRAIN DESIGN FEATURES THIS WATER METER

By H. P. MATTE



Sectional Elevation of the 5/8-inch, 3/4-inch and 1-inch Worthington Meter with Enclosed Grease Train, Described in the Accompanying Article.

THE Worthington Model G. Meter has several features that are outstanding and unique, the most important being the design of the train, the frost and water hammer protection, interchangeability of train parts in all sizes, the use of Monel Metal in all parts subject to corrosion, and the adaptability of the same meter to both the open and enclosed train construction, with the option of the frost protection feature on either type.

Model G Disc meter was designed especially to prevent corrosion in all classes of service water. The questions of galvanic action, electrolysis, effect of sediment, and all form of foreign matter on gears were considered.

Only One Train Plate

Seventy years' experience in the manufacture of water meters gave an ample background.

The intermediate train has three gears of the same size giving a reduction in speed from the disc to the register of 166 to 1, resulting in extreme sensitiveness. The interesting and unusual departure from older designs is the fact that there is only one train plate in the meter. This, apart from reducing the corrosion hazards greatly simplifies maintenance costs because the train is not a separate unit. The removal of three Monel Metal screws releases the train plate and permits the displacement of the gears for examination and cleaning . The top plate or upper bearing is the meter body. If a new part is required it is easily placed into position without the necessity of a complete train.

The gears, pinions, spindles and train plates are interchangeable in all sizes. The train plates have capped rubber bushings, while the top bearings, also rubber bushed are capped by the top case. Thus, sand and other forms of sediment are kept from the bearings.

The Model G train is so constructed that the parts move freely with almost no friction. The thickness and diameter of the gears, the diameter of the spindles, the metal used in the wearing parts, the use of rubber bushed bearings, the arrangement of the various metals in the construction of the meter in the proper electro-motive serial placement, and the minimum number of parts; have all been considered carefully in order to reduce the corrosive factors, and to lengthen the life of the train.

Disc Chambers Described

The disc chambers are made in two sections. Care has been taken in the selection of the bronze to prevent galvanic action and increase the resistance to wear through the motion of the disc. In addition the disc or measuring chamber diaphragm is monel metal. All discs are made of hard rubber reinforced with metal in order to insure resistance to water hammer and other shocks. The spindle is also of monel.

The flow of water in this meter is direct from the outlet port of the measuring chamber; thus, capacity is increased to such an extent that the smallest meter, the 5/8" size is continuously being used in place of the older 3/4" meters. This is a material saving to the ultimate consumer.

Easy to Repair

The work of repairing a Worthington Model G meter is so simple that no mechanical ability is necessary. The tools required are a minimum—a screw driver and any wrench. It is impossible to make an error in assembling the parts. No particular care must be taken to place the gears in the proper sequence because the second and third gears are interchangeable, the first pinion is fastened to the train plate and is removed with it, and the third gear can fit only in the top case as the spindle passes through the stuffing-box. There is no intermediate pawl to adjust. An important point is the casting of the stuffing box into the top case. This eliminates another gasket and another point for leakage.

The main case is provided with a

round rubber gasket which fits into a groove in the bottom case. This guards against the blowing out of main gaskets under high pressures.

The Worthington frost protection feature is very effective and simple, too. It consists of a clamp made of a specially mixed metal and of a particular design to yield under the action of frost. One clamp is placed between the head of each bolt and the main case. This permits the separation of the two halves of the outer casing, and in the event of a severe frost or extreme separation, the disc chamber having no screws to keep the halves together will separate also without distortion. These clamps are also very useful in counteracting the effect of water hammer in contrast to a rigid breakable frost protection construction.

MEASURING "MUDDY" WATER

While the Worthington Model G meter fitted with an open type train has proved to be efficient under most conditions of service there are times when the meters are called upon to measure water which contains much sediment, iron or clay or even sand. It is evident therefore the wearing out of the moving parts will be accelerated. For this reason the oil enclosed train may be used to advantage. This is accomplished by substituting a solid train plate for the skeleton plate. When this change is made the entire working mechanism of the meter is separated from the service water.

In order to ward off corrosion a special oil is placed in the gear compartment. This remains on the gears and spindles and requires no further attention.

Model G meter is made in 5/8", 3/4", 1", 1½", and 2" sizes. The metals used in the construction are various bronzes and monel metal. Forged bronze bolts are provided for the main casing. The four screws in the interior of the meter are of monel metal.

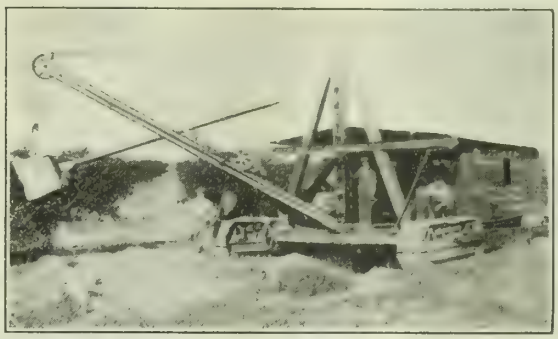
Business Men Finance Survey

Business men of Roundup, Montana, will advance the money necessary to make a preliminary survey to determine boundaries of the Lake Mason irrigation project, according to action recently taken by the Commercial Club. The cost of this survey is estimated at not to exceed $1,500. If the irrigation district is eventually created, the cost of the survey will be assessed against the land embraced in the district and the money now advanced will be refunded. Two independent projects are being discussed, the Lake Mason project, and the Musselshell river project.

For Cleanout -- Maintenance -- New Ditches

There's a Bay City for Every Job

BAY CITY Land Dredges span the ditch, can dig any desired slope, and dump waste on both banks. BAY CITIES leave clean, wide berms, and can work up or down streams. One trip over the ditch is enough. The Shovel Type Dipper handles hard material in which other types of buckets cannot make a good showing.



At left—One yard BAY CITY Dredge digging and cleaning ditches in Florida Citrus Groves.

BAY CITY Land Dipper Dredges are built to fit the job. Walking, Crawler, Track or Floating mounting. Easily dismantled, transported and assembled. Capacities ½ to 1½ cubic yards. Oil engine or electric operation.

FOR SMALLER DITCHES — OR PIPE LINE TRENCHES

The BAY CITY 16-B convertible Excavator will handle a wide range of work. Operates Dragline, Trench Shovel, Clamshell or Skimmer. All steel. Shipped assembled. Digs any width or depth up to 20 feet.

STEEL CONSTRUCTION

¾-yd. capacity

FULL CRAWLER MOUNTING

or—Model 4 Excavator

BAY CITY Model 4 is a small low-priced convertible, one-man operated Excavator. Fills the gap between hand labor and high priced equipment. Capacity 20 to 40 cubic yards per hour. Gasoline or electric power. A Real Digger economically designed for the small job. Also operates shovel, and clamshell.

HIGH PRESSURE CONCRETE LINE

The photograph shows a 10-inch high pressure line of 120 pounds pumping pressure, which is being installed on the Captain Sills Spaulding Ranch, north of Santa Barbara, Calif. The ditch in this photograph is 16 feet deep and the pipe will have an overtopping of 30 feet. This high pressure concrete pipe is of recent manufacture, especially on the Pacific Coast. The Western Concrete Pipe Company is putting in several thousand feet of it on the Spaulding Ranch.

Issue Engine Bulletin

The Underwriters' Laboratories, which are maintained by the National Board of Fire Underwriters, have recently listed as standard, Climax "R4U" and "R6U" Engines for driving 750 and 1,000 gallon multi-stage centrifugal fire pumps. It is understood that these engines are the only medium speed, heavy duty engines to be so listed by the Underwriters' Laboratories.

A new bulletin describing these engines has just been issued by the Climax Engineering Company, Clinton, Iowa. Basically this engine is the same that has been previously used as power for cranes, shovels, gasoline locomotives, and kindred equipment. It has been equipped to meet the requirements of the Underwriters.

A. L. Graves, master mechanic of the Imperial Irrigation District has sent out an invitation to the ranchers of the district to visit the shops at any time. During the last year a number of lathes and other pieces of machinery have been installed so that it is now possible for the shops to do virtually all the repair work on district equipment.

Irrigation Equipment Shown at California State Fair

Pump Tent Houses Attractive Displays of Western Irrigation Equipment Association at Sacramento.

Farm machinery of every description, including pumps, pipe and other strictly irrigation equipment were displayed by manufacturers of equipment who were represented at the annual California State Fair, held in Sacramento the week of September 4th to 11th.

In what is generally referred to as

A general view of the 'pump tent" which housed the exhibits of the irrigation equipment manufacturers at the California State Fair.

One of the attractive exhibits, that of the Byron Jackson Pump Manufacturing Company.

The Price Pump exhibit

the Pump Tent, members of the Western Irrigation Equipment Association dominated the displays. Among the association exhibitors were W. R. Ames, manufacturer of surface irrigation pipe; Price Pump & Engine Co., who displayed a combination irrigation and pressure system connected to a deep well pump, and a 3,000 gallon double suction centrifugal pump.

Westco Chippewa Pump Company exhibited their pressure systems and plunger pumps, and Crane Company had a similar display of small pressure systems and household pumps.

The largest exhibit in the pump field was the comprehensive set up of the Byron Jackson Pump Mfg. Co., who displayed ten pumps of various sizes, some seven or eight of which were operating under pressure.

J. W. Bird was showing a new type of four cylinder deep-well pump. The pump exhibit of the Bean Spray Pump Co. was a deep well turbine pump.

Frank J. Kimball Company had two deep well pumps and two low-lift large capacity pumps. Two deep well turbines were the offering of the Western Well Works. The next booth occupied by the Pacific Pump and Supply Co., featured Meyers water supply systems and power sprayers.

A large display of motors, engines, pumps and farm machinery was grouped under the Fairbanks Morse & Company sign. The deep-well equipment manufactured by the Pelton Water Wheel Company was displayed in cooperation with the California Mechanical and Electrical Engineering Co. Concrete pipe and concrete farm and irrigation supplies were featured by the J. J. Merritt Co.

This completed the exhibit of those who were located in the pump tent. In various other locations around the fair grounds could be seen the exhibits of the Caterpillar Tractor Co., who displayed tractors ranging in size from the smallest to the largest models; the California Corrugated Culvert Co., who showed corrugated metal culverts, flumes, and irrigation gates, and the Trakford Co.

Automatic Gates Solve Problem

The Nevada Highway Department was faced with a difficulty recently, which, to the casual observer, would seem unlikely for a state usually thought of as very arid.

The Truckee Meadows in Washoe County are drained by what is known as the Peoples Drainage Ditch which empties into the Truckee River. During high water in the river, the water had a tendency to enter the Peoples Drainage

Thirty-six-inch automatic drainage gates draining Peoples Drainage Ditch into Truckee River, Nevada.

Ditch, reflooding the lands. However, the problem was solved by the installation of two thirty-six-inch Calco automatic drainage gates which allow all water being drained from the Meadows to enter the Truckee River, but at the first sign of high-water in the river, automatically close, preventing back-flow.

New Post for Utley

One of the interesting announcements of the last thirty days, in irrigation trade

C. A. UTLEY

circles on the Pacific Coast, was that of the resignation of C. A. Utley of the Pelton Water Wheel Company of San Francisco, California, to become president and general manager of the California Mechanical and Electrical Engineering Company of Sacramento.

Mr. Utley has been associated with the Pelton Water Wheel Company for many years in charge of the irrigation department and is one of the best known irrigation equipment men of the west, having been one of the organizers of the Western Irrigation Equipment Association, of which he was the first president. He has served this organization as secretary for the past several years and has been a strong personal factor in making it a constructive force in the irrigation world of the Pacific Coast.

Mr. Utley has announced his resignation as secretary of the W. I. E. A., in order to devote his entire time to the duties of his new connection but, inasmuch as the California Mechanical and Electric Engineering Company are members of the Association, he expects to continue to maintain a close interest in the organization.

San Francisco Survey Shows Urgency of Water Needs

(Continued from Page 41)

erty, the water requirement remains practically unchanged. The foregoing data substantiate this fact and indicate that the same rule holds for other California cities of similar kind including those in the Bay region. For communities with greater population density, however, the rule does not hold. San Francisco with a population density of over twice that of the built-up portions of Los Angeles has an acre use of approximately twice the local irrigation requirement, even though its present use is considerably below the average for American cities.

Similarly, in the congested portions of Los Angeles the use is considerably in excess of the irrigation requirement. As the larger California residential cities increase in population density or the nature of the water requirement is modified, there will undoubtedly be a departure from the present rule. For residential districts, however, the rule will probably not be modified. The analysis above shows clearly the limitations within which the urban water requirement per acre can be considered as identical with that for irrigation.

The intensively developed portions of the San Francisco Bay metropolitan area will presumably consist ultimately of the two densely populated centers of San Francisco and Oakland, surrounded by industrial and residential sections. Smaller centers will occur at more distant points, such as San Jose, Palo Alto, San Rafael, Vallejo, Santa Rosa, Napa, Martinez, etc., and in the intervening regions will be industrial districts, suburban residential sections, and rural areas.

Water for irrigation is required throughout the Bay region, both for beautified country estates and intensive agriculture. Industry also requires large amounts of water, the amount being indicated for a selected district in Los Angeles in Table 2. It may be assumed, therefore, that in its ultimate state of development practically every occupied acre of the 876,000 acres of the metropolitan area will have a potential demand for a reliable supply of water.

How Demand Was Estimated

In determining the probable total future demand for water in the Bay region all available data of water consumption were considered, including those presented above. The local conditions of the different communities as they affect water consumption were also considered, such as relative cost of distributing, use for gardens, industrial use, etc. The

16th and Alabama Streets

probable nature of future development, whether urban, suburban, industrial, or agricultural, was also taken into consideration. In San Francisco, for example, it is believed that, although the use of water per capita as well as per acre will increase considerably over the present rate, yet because of the inherently high cost of delivering water to this area, and the comparatively small use for gardens, it will never reach the average for American cities with similar density of population.

In the East Bay region, however, it is believed that, with the provision of an adequate supply resulting in increased industrial and garden use, the present delivery per acre will almost treble and the per capita consumption be doubled, bringing the rate up to the average for American cities in the same class. The demand for industrial and agricultural purposes was also assumed in accordance with the data presented above.

In the North Bay region and in Livermore and Amador valleys, it is believed that there will always be about thirty-three per cent of the agricultural land not using water, the owners either preferring to dry-farm in certain years, or to rotate and allow a portion of the land to lie fallow each year. The result of the determination of the ultimate demand for water for all purposes in the San Francisco Bay metropolitan area indicates a total of 1,074 million gallons per day. The details of the estimate are shown in Table 3.

Future Sources of Supply

Development of local water resources to meet the growing demands of the Bay region will naturally continue until a limit is reached. This limit will be controlled by the relative cost of developing local and distant sources. The water-bearing gravel beds immediately surrounding the Bay and in the adjacent valleys have already been fully developed by means of wells and pumping plants and cannot be depended upon for additional supply. In fact, in most localities they are being overdrawn, and in the near future their use must be temporarily discontinued until the depleted reserves have opportunity to recover.

The unregulated winter run-off from rainfall on the productive watersheds immediately tributary to the Bay is the only remaining local source of undeveloped water. Storage must be constructed to conserve this water, either by collecting it in surface reservoirs or causing it to be absorbed by the porous gravels underlying the valleys. The great cost of the necessary lands and the construction which is required is a limiting factor in the supply. Run-off differs in amount from year to year, and periods of several years in succession occur when there would be no additions to reservoir supply. A large percentage of any additional reservoir capacity must thus stand idle for extended periods of time unless capable of being utilized for storage of water from distant as well as local sources. In a few instances this is possible, an example being the Upper San Leandro Reservoir now being constructed by the East Bay Water Company.

Sources of Further Supply

The watersheds of local streams tributary to San Francisco Bay are shown on Plate 1, together with lines of equal annual rainfall. The productive drainage areas, where storage sites are developed or proposed, are indicated by heavy shading. These lie within the areas of heaviest rainfall. The most important areas capable of further development by storage are those drained by Lagunitas Creek in Marin County, Los Gatos and Coyote creeks and other smaller streams in Santa Clara County, and by Alameda Creek. The latter is controlled by the Spring Valley Water Company, and its further development will augment the supply of San Francisco. The other streams are controlled by local agencies and will be used locally.

The East Bay and Peninsula regions are without local resources to meet the needs of their rapidly growing urban population, and development in the valleys of Sonoma, Napa, and Solano counties has practically reached the limit of local sources. By expensive conservation works considerable additional water can be developed in the Santa Clara Valley, but concerted action is necessary to accomplish this. Thus far all efforts made to organize a local district have failed.

The amount of water now developed from local sources for the supply of communities in the future metropolitan area is approximately one hundred million gallons per day. Agencies within the present metropolitan district are supplying eighty million gallons per day, and in the surrounding areas the San Jose Water Company, Port Costa Water Company, Bear Gulch Water Company, Petaluma Water and Power Company, Napa City Water Company, and the cities of Vallejo, Palo Alto, Redwood City, and other agencies are furnishing an additional twenty million gallons per day. Most of these agencies have reached the limit of their local sources and some are already drawing heavily upon reserves.

The Spring Valley Water Company on Alameda Creek, the San Jose Water Company on Los Gatos Creek, and the Marin Municipal Water District on Lagunitas Creek still have undeveloped sources which can be made available by storage of winter run-off. The Spring Valley Water Company development at Calaveras Reservoir is the largest single additional unit. Smaller additions might be made on other streams. The amounts which could be thus made available are variously estimated, being controlled to a large extent by economic considerations.

It has been conservatively estimated that sixty million gallons per day, in addition to the present developed supply, could be obtained by complete storage of winter run-off in streams which are available to existing agencies. The resources of the Santa Clara Valley, if comprehensively developed by a district embracing the entire valley, might bring up the total supply for this valley to ninety million gallons per day. The total possible local development would then be 250 million gallons per day as compared with the ultimate total demand of over one billion gallons per day. It is obvious that large quantities of water must be brought in from distant sources if the Bay region is to grow to its ultimate possibilities.

The various Sierra streams, the Sacramento and San Joaquin rivers near the head of Suisun Bay, and the Eel River, are the important distant sources of supply. Three of these have already been definitely selected. Construction work is in progress by the East Bay Municipal Utility District on a system to bring an emergency supply of fifty million gallons per day from the San Joaquin River. Later this system is to be extended and a permanent supply of 200 million gallons daily developed on the Mokelumne River. This system has the location and elevation which will enable it to serve not alone the territory now served by the East Bay Water Company in Alameda County including Richmond and El Cerrito, but the Bay shore and interior valleys of Contra Costa County. The immediate plans of the District are to serve the area now covered by the East Bay Water Company system, with extensions into other areas as the demand occurs.

Hetch Hetchy Project

The city of San Francisco has been actively pushing construction on the mountain divisions of its Hetch Hetchy project on the Tuolumne River, and is preparing to start work in the Sierra foothills. This project is so laid out that when built it could serve the Peninsula, the whole southern end of the Bay, and the East Bay region, as well as the present city and county of San Francisco. The supply which can be developed under the rights which the city owns has been variously estimated, and has been found by several independent determinations, including a detailed study made by the writer, to be from 375 to 400

TABLE 4

RELATION OF FUTURE WATER SUPPLY TO DEMAND FOR SAN FRANCISCO BAY METROPOLITAN AREA

(In Million Gallons per Day)

Region	Ultimate Demand	Ultimate Local Supply	Deficiency in Local Supply	Distant Sources	
				Location	Amount
North Bay	295	30	265	Eel River	200
				Russian or Sacramento River	65
East Bay cities	144	37	354	Sacramento-San Joaquin River	.....
East Bay shore and interior valleys	245			Mokelumne River	200
				Hetch Hetchy	154
San Francisco City and County	84+	80	4+	Hetch Hetch	20
Peninsula	99	15	84	Hetch Hetchy	84
Santa Clara Valley	207	90	117	Hetch Hetchy	117
Total	1,074	252	824		840

million gallons daily. It may be conservatively stated that the dependable Tuolumne River supply available to San Francisco under its rights, and in excess of the local irrigation demands as limited by economic requirements, is not less than 375 million gallons daily.

This assumes, however, that San Francisco proceeds continuously and diligently in the prosecution of construction work on its water-supply project, of which there still remains to be completed the Sierra Foothill, Valley, and Coast Range divisions.

The nucleus of a project for development of the Eel River has been completed by the Snow Mountain Water and Power Company by the construction of the Van Arsdale and Pillsbury reservoirs. The water level at the latter can now be raised to 110 feet above the stream bed with flash boards placed upon the dam. It is proposed to raise the dam to a height of 150 feet. This source is nearest the North Bay valleys, and in the proposed plan of the State Engineer for comprehensive development of the water resources of the state, has been indicated as the most feasible one for this region. It has also been considered as a possible source of supply for the Bay shore of Contra Costa County and the East Bay region. The dependable supply, with a 150-foot dam at Pillsbury Reservoir, has been estimated at from 168 to 250 million gallons daily, and for the purpose of this paper will be assumed at 200 million gallons per day.

Still Not Enough

It is apparent from the above, that the three projects already initiated to bring in water from distant sources, if consummated to the full extent proposed, would barely supply the future demands of the Bay region even with a full development of local sources. The Eel River supply with a higher dam at Pillsbury, is insufficient for the future needs of the North Bay region, and will have to be supplemented either by further development on other branches of the Eel, or by water from the Russian or Sacramento rivers or both.

The proposed Mokelumne supply, although sufficient for the future needs of the East Bay cities, is far from being enough to supply the adjacent regions such as the Bay shore north of Richmond and south of San Leandro, and the interior valleys of Contra Costa and Alameda counties. The East Bay region will ultimately have to draw upon additional sources, the Hetch Hetchy project being the logical one for southern Alameda County and the Sacramento-San Joaquin River supply for Contra Costa County.

Situation Summarized

The city and county of San Francisco, as long as it is dependent entirely upon local sources, will periodically face periods of drought which will threaten the continuity of its supply. The rainfall of the past eight years has been below normal, and ground storage has become so depleted that the run-off of the past two years has been little or nothing. With the experience of the past few years the city cannot longer afford to gamble upon the continued adequacy of local supplies.

Table 4 briefly summarizes the water situation, and indicates in figures the relations of supply and future demand in the various subdivisions of the Bay region. The conclusion may be drawn that the fully developed local sources and the three definitely initiated distant sources will all be required. A supply from the winter and spring flows of the Sacramento-San Joaquin rivers will also be necessary. The latter may be considered only as an auxiliary and reserve supply, but in view of its relatively low cost and the efficiency of modern filtration methods, it might ultimately become one of the major supplies.

Homer J. Gault has been appointed construction engineer on the Stony Gorge Dam on the Orland project, California.

Assistant engineer R. R. Robinson, formerly connected with the Salt Lake Basin project, has been transferred to the Kittitas division of the Yakima project, Washington.

Associate engineer A. C. Jaquith, who has designed several large dams for the reclamation bureau, has resigned his position with the Denver office of the bureau and has accepted a similar position in Mexico.

Assistant engineer J. H. Yates and Superintendent L. E. Foster, of the Carlsbad project, New Mexico, recently made a trip through the upper part of the Gallinas watershed on matters relating to the Pecos River adjudication.

Harry N. Jenks, who has been for some years superintendent of the pumping and filtration works at Sacramento, California, has gone to Iowa State College, Ames, Iowa, as associate professor in charge of sanitary engineering subjects.

J. L. Savage, designing engineer of the reclamation bureau, has recently been on the Kittitas division of the Yakima project, Washington. He was studying principally the problems affecting the construction of the next ten miles of the main canal.

M. T. Clemans, president of the Florence-Casa Grande Water Users' Association, Arizona, has sent out a statement urging that all contracts asking for inclusion of lands within the San Carlos project be signed and sent to the Florence office at once. "The Indian service officials," he says, "asked that all contracts be in as early in October as possible so that congress and the budget committee could not feel that there was any hesitancy on the part of land owners toward signing up—a condition that might cause unnecessary delay."

Attorney Samuel J. Flickinger, of the division of irrigation, Department of the Interior, attended a meeting held in Florence, Arizona, the latter part of September between the board of directors of the Florence-Casa Grande Water Users' Association and the officials of the Indian Service. Mr. Flickinger was in the valley making a personal inspection of the progress being made in project matters.

Representative A. M. Wyant, of Pennsylvania, visited Los Angeles the latter part of September on a nation-wide tour of inspection of government public works, agricultural districts and waterways. In an interview here Mr. Wyant declared himself in favor of the Columbia River project, of the development of the Colorado River, and of river improvements. "I believe the Boulder Dam project is necessary for the development of the resources of this district," Mr. Wyant stated.

A. L. Wisker, general manager of the Nevada Irrigation District, and Fred H. Tibbetts, chief engineer, had as their guests on a three-day trip over the Mountain Division of the district early in September twenty-four members of the Sacramento section of the American Society of Civil Engineers. The party left Sacramento on a Saturday noon and went by way of Grass Valley to Bowman Lake where they spent Saturday and Sunday nights. From here side trips were made to the various parts of the project.

George S. Hinckley, city engineer of Redlands, California, was the principal speaker at a recent meeting of the water users of the Hemet-San Jacinto Valley water system. Mr. Hinckley stressed the fact that a community can grow only as the water is developed for the use of that community. He stated that people are beginning to learn that by pooling their interests more water can be developed, and they are learning also that long drawn-out litigation does not provide any more water and usually results in a disadvantage for all concerned.

J. C. Bradbury, who is in charge of operations on the proposed Walnut Grove dam on the Hassayampa river, in Arizona, reports that work on a diversion channel, 329 feet in length, and for about half of the way drilled through solid rock, has just been completed. This channel is to carry water from the river bed away from the base of the dam which is to be constructed. Preliminary surveys have been made for an upper and a lower dam, about 24 miles apart. A storage capacity of 60,000 acre feet of water for each dam will reclaim approximately 20,000 acres of land, now used for grazing purposes.

E. C. LaRue, of Pasadena, California, hydraulic engineer of the United States geological survey, with an expedition of eight men is conducting a survey of the Little Colorado, one of the important tributaries of the Colorado River. The region now being surveyed by the engineers has been entered only once before by a party of white men, and the work is being carried on in the virgin territory under tremendous handicaps. Quicksands are prevalent in places, and for this reason the party is equipped with light sand-sailboats to transport the men and supplies across the treacherous sands. The present government survey is the first that has ever been made in the Little Colorado..

Louis C. Hill, formerly supervising engineer of the Bureau of Reclamation, stopped at the El Paso office of the Rio Grande project on his return from a trip to Mexico. Mr. Hill is one of the members of the board of engineers who will review all hydrographic and geologic data pertaining to the feasibility of the proposed new dam site between Avalon and McMillan reservoirs on the Carlsbad project, New Mexico. Mr. Hill will represent the interests of the water users at Carlsbad and Ft. Sumner. The other members of the board are S. O. Harper, assistant chief engineer of the bureau, who will represent the bureau; and Oro McDermith, who will represent the Secretary of the Interior.

Marcelo Leon, an engineer with the Mexican Government, was a recent visitor to the Boise project, Idaho.

S. O. Harper, general superintendent of construction, bureau of reclamation, has recently visited a number of the projects in the northwest.

Charles E. Scott, El Centro, California, represented the Imperial Valley associated chambers of commerce at the Winning the West Conference, held in Los Angeles, October 14 and 15.

Andrew Weiss, assistant director of reclamation economics, has resigned his position with the bureau of reclamation to become associated with J. G. White Engineering Corporation in Mexico.

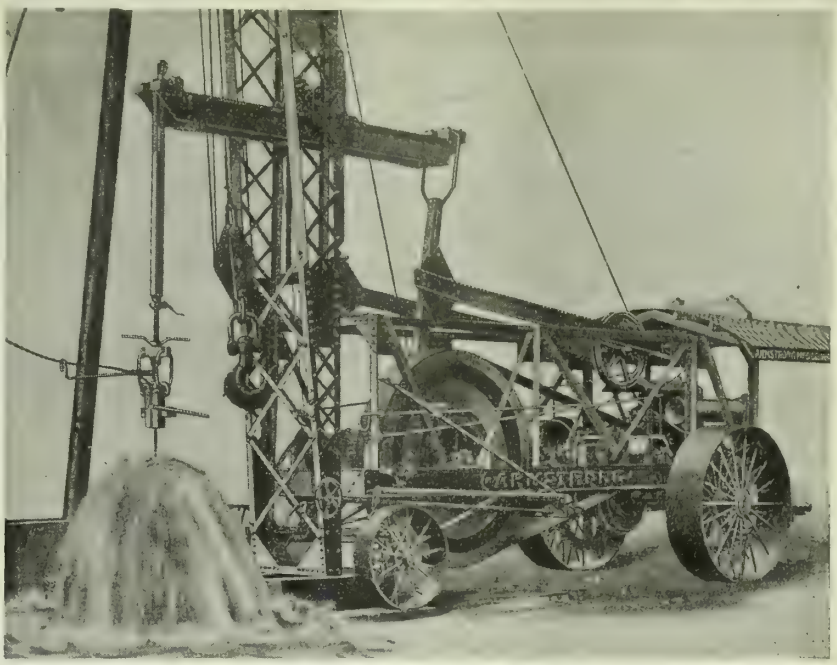
Major C. R. Olberg, assistant chief engineer of the Coolidge Dam, San Carlos project, Arizona, discussed the features of the dam's proposed construction before the delegates to the Winning of the West convention in Los Angeles on October 15.

Former Governor Thomas E. Campbell, recently chairman of the fact-finding commission, has been overseeing the technical details and historical data concerning the development of the Colorado River and reclamation work in connection with the filming of a new motion picture.

Dr. John A. Widtsoe, who was one of the principal speakers at the meeting of the Montana Irrigation and Drainage Institute, held at Valier, Montana, made a brief inspection of the Greenfields division of the SunRiver project while on his way from Valier to Great Falls.

Maurice G. Ricker, photographer and editor of motion-picture films, has returned to the Washington office of the Bureau of Reclamation after an extensive trip over a number of the irrigation projects. During the course of the trip he took more than 1,000 still pictures and about 15,000 feet of motion pictures.

Harry Lee Martin was elected president of the Tulare Lake Basin Water Storage District at a meeting of the directors held at Hanford, California, on October 6. The district is working for the development of a storage reservoir in the basin of Tulare Lake, with an area of some 20,000 acres, to take care of excess water in flood years and to hold in reserve surplus waters for irrigation.



The Armstrong All-Steel Drill

"Built for Service Since 1867"

THE frame and derrick of the ARMSTRONG DRILL are all steel. The main sills of the frame are steel channel. The upper part is made of steel angle bars, with braces and trusses all hot riveted in place. There are no nuts, screws, nor bolts to get loose or drop out. There is nothing about it to rot, rust, check, crack, break or wear out. It is as rigid as the skeleton of a sky scraper—as strong as a steel bridge—built to last an age. It cannot warp, spring nor twist out of shape, and always holds the shafting and bearing in perfect alignment. It has been designed and built for maximum strength and long life.

LEGAL *and* JUDICIAL

A DEPARTMENT CONDUCTED BY HANKINS & HANKINS

Claimant Need Not Publicly Announce his Adverse Claims

Whether claim of an easement for a ditch is adverse or merely permissive is a question of fact.

In the case of Stetson vs. Youngquist 248 Pac. Rep. 196 (July 8th, 1926) the plaintiff claimed the right to the use of a ditch crossing the defendant's lands. The plaintiff purchased his land in 1909 and constructed the ditch in 1911. The ditch was used from that period and no direct objection was made to its use and no direct claim of right, other than the use, was made by the user.

In 1925 the relations between the parties became somewhat strained and defendant refused to allow plaintiff further use of the ditch. Plaintiff claims an adverse and prescriptive right to the perpetual use of the ditch and defendant claims that the use was merely permissive and therefore a revocable license.

In reviewing the law and the facts and in giving judgment for plaintiff the Supreme Court of Montana, states:

"Plaintiff constructed his ditch upon defendant's land on the theory that he had the right to do so and has ever since maintained the ditch there. He has shown an open, visible, continuous, and unmolested use of the ditch for the period of time sufficient to acquire title by adverse possession. In the absence of any evidence on the subject, the use under such circumstances, is presumed to be under a claim of right and not by license of the owner. In order to overcome this presumption, thereby saving his title from the incumbrance of an easement, the burden is upon the owner to show that the use was permissive. When the claimant's use has been thus open, continuous, unmolested and under a claim of right, it is deemed to have been adverse to the owner. . . . . If the character of the possession is such that a claim of ownership may be inferred therefrom, and is open and notorious, it is hostile. It is not necessary that one should expressly declare his possession to be hostile, or that his use of the premises should be such as to indicate at all times a hostile occupancy. . . . the question of adverse possession is one of intention. The intention must be discovered from all the circumstances of the case."

Utah Ruling on Suit to Adjudicate Water Rights

All users must be made parties to suit; findings of court must be definite and certain.

In the case of Garner vs. Anderson 248 Pac. Rep. 496 (June 4th, 1926) the trial court attempted to adjudicate the water rights on a small mountain stream known as Burch Creek. Certain water users were not joined, the decree did not allot definite amounts to various owners of lands and opinion evidence was allowed as to the amount necessary to irrigate certain lands with no showing of the qualification of witnesses to testify to such matters.

In reversing the judgment of the trial court, the Supreme Court of Utah states:

"We do not wish to be understood as holding nor do we hold, that a farmer or other who has had experience in actually irrigating lands cannot give his judgment, if he has any judgment, as to the quantity of water necessary to irrigate particular lands. The difficulty with the witnesses in this case is that they stated they had never measured water, did not know or claim to know, the actual amount of water used in the irrigation of their individual lands or the lands of other parties to the action. At most it was a mere guess as to the quantity of water necessary for the irrigation of either respondent's or appellant's lands. . . . . .

If it were the theory of the plaintiffs that others not parties to the action were entitled to the use of the waters as tenants in common, such fact, in the absence of pleadings and in the absence of the parties, would deny the court the right to make such adjudication. . . . .. Any judgment consented to by the parties before the court would in no way affect the rights of the others not parties to this proceeding. . . . . There is not sufficient data in the record from or by which this court can determine the rights of the plaintiffs or the defendant in the waters of the creek. The number of acres irrigated by the plaintiffs and which they have a right to irrigate is not very conclusively proven. There is no map or other record from which or by which a reviewing court can get an intelligent idea of the acreage or its location to other parts of the land claimed by the plaintiffs or by "others not parties to the action" . . . Plaintiff's rights to the water, as indicated, are established, but the quantity of water to which they are entitled is not established. . . .

New Mexico Irrigation Bonds Payable Outside State

Laws of New Mexico do not follow the conclusions of the Supreme Court of California.

In the case of Davy vs. Day 247 Pac. Rep. 842 (June 17, 1926) an objection is raised to the issuance of bonds of the Bluewater-Toltec Irrigation District, which bonds are proposed to be made payable either in New Mexico or New York.

In supporting the provisions making such bonds payable in New York, the Supreme Court of New Mexico states:

"The whole argument of appellant is based upon the provisions of Sec. 10 of Article 8 of the Constitution, which is as follows:

'All public moneys . . . . shall be deposited in national banks in this state. . . .'

The argument is made that, in order to pay a bond, made payable at any place, it will be necessary to deposit public moneys at such place to effectuate that result. Therefore, it is argued, in order to pay a bond made payable at some bank in New York, for instance, it would be necessary to deposit the public funds with such bank for such purpose. This is clearly a misconception of the sense in which the word "deposited" is used in the Constitutional provision above quoted. The provision is one for the safe keeping of the public funds while the same are not being used for the public purposes. It is not designed nor intended to hamper or prevent the doing of the business of this state according to the methods employed throughout the business world. . . . . When they (funds) are required to meet the public obligations, they may be expended in a business way, and according to business methods and practices.

Counsel cites and relies upon Los Angeles v Teed 112 Cal 319. The case is in point and sustains the contentions of appellant. While we have uniform respect for the decisions of California, we are compelled to decline to follow this one as unsuitable to our situation and the policy of our laws."

Irrigation Taxes Are Special, Not General Liens.

Under the Colorado Irrigation District Laws, District Assessments cannot be cumulated.

In the case of Thomas vs. Henrylyn Irrigation District 247 Pac. Rep. 1059; (July 6th, 1926) the Supreme Court of Colorado follows the rule of law enunciated in the case of Interstate Trust Company vs. M. V. Irrigation District, (181 Pac. 123) called "the Montezuma Case" also a Colorado case, and holds as follows:

"In the Montezuma Case we held that taxes levied under the act are not general, but special; hence there could be no cumulative levy, and the holder of warrants was confined to the proceeds of the regular levy and sale. If taxpayers are delinquent, he may use his warrants to buy at the sale and procure deeds on his certificates; he could not demand a new levy and thus pyramid the debt of those who do not pay on the lands of those who do. It is here contended that the Montezuma Case is not in point, because there warrants were involved and here bonds and coupons. The control-

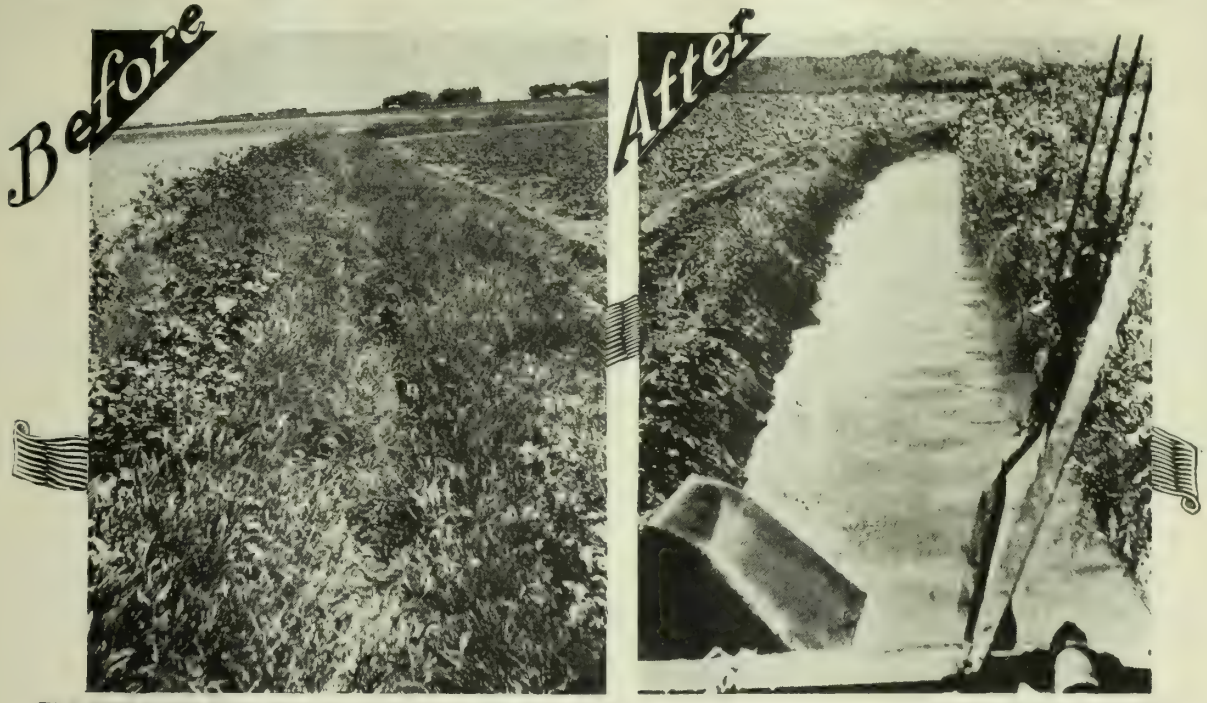
Digging, Cleaning Canals - *at Low Cost*



THE NEW RUTH DREDGER digs successfully in either dry or swampy ground. With its quick adjustable elevator, operating from either side of the dredger and its high speed endless chain of automatic self-emptying buckets and consequent uninterrupted flow of dirt, and ease of mobility, it operates at a minimum cost per cubic yard or lineal foot, heretofore considered impossible.

The RUTH cuts smooth even banks and bottoms—cleans canals, whether empty or filled with water, of all muck, sand, tulles, small willows and water grasses.

Write describing the type of work you contemplate doing and our engineers will gladly co-operate with you in selecting the dredger best adapted to your needs.

Send today for BULLETIN No. 9—it illustrates the NEW RUTH DREDGER, type and size of canals it digs or cleans, and gives specifications, maximum capacities, and operating costs.

IRRIGATION ENGINEERING

By ARTHUR POWELL DAVIS, D. SC.

Chief Engineer and General Manager, East Bay Municipal Utilities District; formerly President Am. Soc. C. E.; formerly Director and Chief Engineer, U. S. Reclamation Service.

AND

HERBERT M. WILSON, C. E.,

Mem. Am. Soc. C. E.; former Chief Engineer and Irrigation Engineer, U. S. Geological Survey.

Seventh Edition, Revised and Enlarged; Total Issue 12,000

THIS IS a rewritten and rearranged edition with much new material added. The principal difference introduced is the treatment of soils, plant food, operation and maintenance, and other lines of work where the duties of the irrigation engineer come in contact with the irrigator, such as in the preparation of land, the duty of water and its application to the land. A bibliography of standard works is given at the end of each chapter. 640 pages. 6 by 9. 249 figures and illustrations. Cloth, $4.50 net postpaid. Remittance must accompany the order. Allow from one to two weeks for transmittal of order and shipment from the publishers.

IRRIGATION PRACTICE *and* ENGINEERING

By B. A. ETCHEVERRY,

Professor of Irrigation Engineering, University of California.

In three volumes—the most comprehensive work in the field. A wealth of information of both practical and informative value for everyone interested in water development and conservation. Prices are net postpaid and remittances must accompany order. Allow from one to two weeks for transmittal of order and shipment from the publishers.

Vol. 1.—Uses of Irrigation Water and Irrigation Practice.....$2.50
Vol. 2.—Conveyance of Water..... 4.00
Vol. 3.—Irrigation Structures and Distribution System..... 4.50

OVERHEAD IRRIGATION

CONDUCTED BY WM. J. B. STEWART

OVERHEAD IRRIGATION IS GAINING GROUND

By FINGAL C. ORR, M. E.

IN THE September issue of MODERN IRRIGATION I touched on the past history of the growth of the overhead industry. What the future holds can be seen by those interested enough to stretch their imagination to a slight degree.

We have thousands of square miles of perfectly good land lying idle in the West today waiting only for the advance guard of civilization, with an adequate supply of water, if properly applied, to transform what are now barren mountains and desert wastes into modern gardens of Eden.

We have a lot of this necessary water in the Colorado River flowing on its way to the sea. It's only a matter of human endeavor, judiciously expended, to bring this water to the land, then to apply it in the most economical form such as is possible by using the overhead system, this system leaving the precipitation of the moisture absolutely under control regardless of the topography of the land, or the nature of its soil.

Used on Irregular Land

Until the introduction of the overhead idea, it was very much of a hit and miss proposition to irrigate sandy soil or irregular ground and there was a deplorable waste of water. The labor entailed in the leveling of the land for furrow irrigation was in itself no small item and was far from satisfactory at best, necessitating as it did in many cases the stripping of the good top soil from some places to fill the hollows in others, which already had their proportion of good top soil. The foregoing proceeding is entirely eliminated by the new method and the irrigation can be applied scientifically and with accuracy.

Where the soil is sandy or light the irrigation can be applied lightly and often, or where of a heavier nature can be adjusted so as to give the ground just the proper amount of water that it is capable of absorbing without running off.

It has been found that overhead irrigation is very helpful in the condition commonly known as "ploughsole" as the water applied this way becomes impregnated with air bubbles which are carried down into the soil, loosening it and delivering their chemical components up to to the soil, an advantage that has long been recognized from our experience with natural rain.

The question has often been raised as to the merits of the system as protection against frost. This phase is still in an experimental state. However, it seems justifiable to conclude, that if the water is turned on during the daytime when a freeze is expected that it will absorb enough sun heat and carry it into the soil, to be given out during the night, to go a long way towards preventing damage; but it is a rather risky experiment to turn the water on as the freeze is in progress, especially if severe, for if the water is not put on faster than it can freeze, it will form ice on the trees and eventually break down the limbs, doing more damage than otherwise.

Eliminates Dust

Overhead irrigation where applied has proved very acceptable not only to those who have to work in the groves, but is blessed by many of the good housewives living close by, as it has practically eliminated the dust nuisance. It also leaves the groves clean and pleasant to enter with the tools.

The writer has before him a quotation from a letter from one of our highest agricultural authorities written back in 1923 in which he says of overhead irrigation:

"The higher the water is thrown the greater the amount of gas absorption from the air will be accomplished. Air oxygen, ammonia gas and dust particles can all be ranked as fertilizing elements and applied directly to the soil itself. This type of irrigation will create moisture which is the real scientific meaning of irrigation i.e. artificially supplying to the soil moisture necessary to agricultural production; and it will supply it at the minimum water expenditure. However its application must be strictly scientific and it would be a vain effort to apply overhead irrigation where the sub-strata is not first made contiguously moist from the impervious strata below to the top of the soil."

Conserves Water

The contentions of this authority made before the overhead idea became an accepted fact, as it is today, are very interesting inasmuch as they have been fully borne out by practical experience gained since that time.

The conservation of water by the new method of irrigation is a very important factor, and taken alone would in many cases warrant its adoption. In looking broadly to the future it is safe to predict that overhead irrigation is with us to stay, and is destined to prove a great boon to the agriculturist and consequently to the world at large.

Limoneira Tests "Overhead"

Reports from the Limoneira Ranch, Santa Paula, California, tell of experiments being tried with overhead irrigation, but state that the system has not yet been in use long enough to compare that system thoroughly with the furrow system. Lemon fruit measurements on large Lisbon trees, says Charles A. Jensen, superintendent of the ranch, showed that the overhead irrigated trees grew lemons about two packing sizes larger than the adjoining trees furrow irrigated, from April 28 to October 6.

On the whole, the amount of water applied in the overhead system in the grove with very large trees was about one-half the amount applied in the furrow system, but this difference is due to the readiness with which the soil takes water. By the furrow system it is practically impossible to get the lower end of the runs wet enough without applying more water than the grove as a whole needs. On the other hand, the overhead system may not be as economical of water in the groves with half grown trees, because the whole soil necessarily gets irrigated whether it needs it or not.

Irrigating Vegetable Crops

(*Continued from Page 19*)

moisture from the soil is proportional to their leaf area hence the need for water is greater as the plants grow larger. As the surface of foliage increases more water will be required to replace the increasing amounts which are constantly being transpired by the bigger plants.

The appearance of the plants is often used as an indicator of the moisture situation. By observing closely the slight changes in color of foliage, growers are often able to irrigate before it is too late. While some experience is required to detect these color developments it is frequently possible to prevent suffering of the plants by acting immediately upon the appearance of the darkened shade and duller aspect of the foliage.

Wilting and curling of the leaf edges is also an indication that large amounts of water are being transpired. The shorter the period of time during the day that this condition lasts the less serious it is.

Maintaining Adequate Moisture

As most of the vegetable crops have a comparatively shallow root system with a large proportion of the roots feeding in the upper strata of the soil, they are rather sensitive to fluctuations in moisture supply particularly if the soil becomes so dry as to check growth. The moisture content of the surface soil is particularly subject to variations following periods of intense heat, drying windstorms, long days of bright sunshine, and spells of low humidity, and the vegetable crops are often seriously injured in yields and quality by a shock due to deficient moisture.

Irregular supplies of moisture often produce second growth and growth cracks in potatoes, puffiness and blossoms end rot in tomatoes, monkey faces and splits in onions, and small sizes in other products, hence vegetables should not suffer from a lack of moisture at any time during the growing season.

Irrigation should be carefully regulated to suit the conditions which prevail at the time and place used for production of the crop. Growers are obliged to give careful attention to the factors which govern moisture conditions and water requirements. In order to regulate the frequency and amount of irrigation it is essential that frequent examinations of the soil in different portions of the field should be made to the depth of the root zone and that a constant and alert lookout be mantained for any indication that the plants need more water.

The soil and the plants also should be closely watched in order to determine the proper time for irrigation, and temperature, humidity, and wind velocity should be considered in connection with the irrigation schedule. Following periods of rapid evaporation and rapid transpiration it may become necessary to apply additional water or to speed up the irrigation under way. Promptness in supplying water at the right time is highly important. Delay may prove dangerous.

Irrigation Before Planting

After the land has been leveled and partially prepared, but early enough to permit weeds to start, to get land in the proper condition for final preparation, and planting operations scheduled at the proper time, the ground is commonly made ready for a preliminary irrigation or flooding. This wetting of the land before the seed beds are made is not absolutely necessary, but it has several important advantages:

Los Angeles' Meter Practice

(*Continued from Page 56*)

at the meter shop. The only work done in the shape of repairs to meters in the field is the renewing of registers that have been broken. Main casings of our velocity meters are left on the service. The cover containing gear train and register is removed and the cage containing propeller is taken out. These parts are then replaced with new ones and the old parts are brought to the shop for repairs. This eliminates a lot of hard and costly work. Our facilities for repairing and testing meters are very good. The shop contains concrete benches equipped with tanks for repairing and concrete benches for storing the meters ready for setting. The machinery consists of a lathe, pipe threading machine, wire wheels for cleaning the outside of meters and exhauster for carrying away the dust, grind stone and carborundum wheels, circular saw for cutting lumber for meter box forms, ball socket machining machine, gauges, press diaphragm cutter, etc. The machines are individually motor driven. Our force consists of a superintendent, who passes on meter parts, whether they are to be repaired or wholly replaced, and sees that every meter is properly repaired (not tinkered with). He also takes care of all repairs to service equipment.

Under him are two testers, a machinist (considered a meter repairer) and 12 meter repairers. Four clerks post maintenance cards, order, receive and account for all meter material received and make monthly reports of meter setting, etc., for Los Angeles, San Pedro and San Fernando Valley. On June 30, 1920, there were 218,635 meters in service, which at this date means one meter repairer for each 18,220 meters in service. The department takes out monthly about one meter for every 166 in service for not operating, due to all causes.

In the last twelve months 429 meters were taken out monthly for failure to operate, due to hot water or steam backing up from boilers or heaters. On the first occurrence of a meter being damaged by hot water or steam supplying a residence, a post card is mailed the

consumer, notifying him and requesting that care be taken to guard against a similar occurrence. On the second occurrence, a bill is rendered the consumer covering the cost of changing and repairing the meter. When meters are likewise damaged, supplying places of business, a bill is rendered on the first offense. The Department advises consumers to watch their heaters and not to use a check valve on their service, as it is cheaper to pay for repairing meter than to run the risk of bursting a boiler.

The organization of the Meter and Service Department consists of a general superintendent with four assistants.

The total force of the meter and service department at this date consists of 375 men, and they cover Los Angeles, San Pedro, San Fernando Valley and the West Gate district.

The city of Los Angeles was incorporated on April 4, 1850, and at that date its total area was 28 square miles. Today it covers an area of 429 square miles.

New service installations for all purposes for the last twelve months, covering all districts, have been at the rate of 1600 per month, and today show no signs of falling off.

On June 30, 1920, we had 240,567 services of all kinds and 218,635 meters.

$14,000,000 Asked for Land

The land owned by the Pacific Gas and Electric Company and by Stephen E. Kieffer and interests represented by him, involved in condemnation proceedings brought by the East Bay Municipal Utility District for use in connection with the proposed Lancha Plana dam and reservoir site, is valued by the defendants at $14,000,000. The land involved is required by the district and the original complaint asked the court to set a value upon it and to force its sale. The Lancha Plana dam and reservoir site is on the Mokelumne River, mostly in Amador County, California, but partly in Calaveras County.

Rice Industry Favored

To aid the rice industry in the vicinity of Merced, California, in growing and developing, directors of the Merced Irrigation District have decided to levy no special toll on rice lands for at least one year. Considerable agitation for a special tax rate on rice lands resulted in the district because of the greater irrigation necessary for rice crops.

SURVEY *of* HYDRAULIC DEVELOPMENT

As Shown by Official Records of the Month -- Local, State, and Governmental

Applications Filed

Among the more important applications for permit to appropriate water filed with the State Department of Public Works, Division of Water Rights, California, during the month of September, 1926, were the following:

Application No. 5183 (Los Angeles County)—W. D. Rawson, c/o D. M. Baker, 1018 Central Bldg., Los Angeles, Calif., for .50 cubic feet per second and 40 acre feet per annum from Cold Creek and Unnamed Creek tributary to Malibu Creek to be diverted in Sec. 17, T 1 S, R 17 W, S. B. M. for domestic, irrigation and recreational purposes in Sec. 17, T 1 S, R 17 W, S. B. M. Estimated cost $10,000.

Application No. 5185 (San Diego County)—La Mesa, Lemon Grove and Spring Valley Irrigation Dist., 121 S. Spring St., La Mesa, Calif., for 50 cubic feet per second and 18,000 acre feet per annum from Santa Ysabel Creek tributary to San Dieguito River to be diverted in Sec. 19, T 12 S, R 3 E, S. B. M. for municipal purposes in towns of La Mesa, El Cajon, Lemon Grove and Spring Valley. Estimated cost $600,000.

Application No. 5187 (Alpine County)—F. C. Springmeyer, Gardnerville, Nev., for 150 acre feet per annum from Bull Lake tributary to E. Carson River via Wolf Creek to be diverted in Sec. 26, T 8 N, R 21 E, M. D. M. for irrigation purposes on 405 acres in Secs. 11, 14 and 15, T 12 N, R 20 E, M. D. M.

Application No. 5192 (Lassen County)—G. L. Kramer, Bieber, Calif., for 500 acre feet per annum from Widow Valley Creek tributary to Pit River to be diverted in Sec. 31, T 39 N, R 7 E, M. D. M. for irrigation purposes on 1000 acres in Secs. 30 and 31, T 39 N, R 7 E, and Secs. 4, 5, 6 and 9, T 38 N, R 7 E.

Application No. 5193 (Nevada County)—Nevada Irrigation District, Grass Valley, Calif., for 5000 acre feet per annum from Middle Yuba River tributary to Feather River to be diverted in Sec. 12, T 19 N, R 12 E, M. D. M. for irrigation purposes on 375,000 acres within said district.

Application No. 5199 (Modoc County)—Frank McArthur, Alturas, Calif., for 4 cubic feet per second and 9000 acre feet per annum from Crooks Canyon drainage area tributary to S. Fork Pit River to be diverted in Sec. 32, T 40 N, R 12 E, M. D. M. for irrigation and domestic purposes on 4680 acres near point of diversion. Estimated cost $75,000.

Application No. 5200 (Los Angeles County)—Arthur B. Caywood, Saugus, Calif., for .025 cubic feet per second from spring tributary to Mint Canyon to be diverted in Sec. 26, T 5 N, R 15 W, M. D. M. for irrigation and domestic purposes on 20 acres in Sec. 35.

Application No. 5201 (San Joaquin County)—Fred H. Finck, c/o Ohm & Raab, Stockton, Calif., for 3 cubic feet per second from Old River tributary to San Joaquin River to be diverted in Sec. 12, T 2 S, R 4 E, M. D. M., for irrigation purposes on 245.3 acres near point of diversion. Estimated cost $4,000.

Application No. 5202 (Ventura County)—Lewis C. and Wm. Plush, Stauffer, Calif., for 1 cubit foot per second from North Fork tributary to Lockwood Creek to be diverted in Sec. 24, T 8 N, R 22 W, S. B. M. for irrigation and domestic purposes on 160 acres in Sec. 29 and 32.

Application No. 5203 (Ventura County)—Glendora Consolidated Mutual Irri. Dist., Glendora, Calif., for 5200 acre feet per annum from Big Dalton and Little Dalton Canyon tributary to San Gabriel River to be diverted in Sec. 20 and 21, T 1 N, R 9 W, S. B. M. for irrigation and domestic purposes on 2461.95 acres.

Application No. 5204 (Butte County)—Mrs. Jennie La Point, Biggs, Calif., for 1 cubic foot per second from Lateral "A" Drainage Ditch of Dist. 833 tributary to Sacramento River to be diverted in Sec. 8, T 18 N, R 2 E, M. D. M. for irrigation purposes on 40 acres of rice in Sec. 8. Estimated cost $200.

Application No. 5207 (Sacramento County)—American River Hydro-Electric Co., c/o S. E. Kieffer, 57 Post St., San Francisco, Calif., for 600 cubic feet per second and 320,000 acre feet per annum from American River to be diverted in Sec. 24, T 10 N, R 7 E, M. D. M. for agricultural and domestic purposes on 150,000 acres adjacent to City of Sacramento between Lincoln and Elk Grove, Folsom and Roseville.

Application No. 5209 (San Joaquin County)—Theo. Lorenzen, et al, c/o Ohm & Raab, Stockton, Calif., for 12.62 cubic feet per second from San Joaquin River tributary to Suisun Bay to be diverted in Sec. 16, T 2 S, R 6 E, M. D. M. for irrigation purposes on 1010.2 acres in Secs. 15, 16, 17, 20, 21 and 29. Estimated cost $12,000.

Application No. 5210 (Solano County)—L. A. Sackett, Winters, Calif., for .75 cubic feet per second from Putah Creek tributary to Sacramento River to be diverted in Sec. 26, T 8 N, R 2 W, M. D. M. for agricultural purposes on 60 acres of land in Sec. 26. Estimated cost $2000.

Application No. 5212 (Butte County)—Willis M. Spesert, Chico, Calif., for 1 cubic foot per second from Rock Creek tributary to Sacramento River to be diverted in Sec. 23, T 23 N, R 1 E, M. D. M. for irrigation and stock purposes on 55 acres in Sec. 23. Estimated cost $250.

Application No. 5215 (Santa Cruz County)—City of Santa Cruz, Santa Cruz, Calif., for 25 cubic feet per second from San Lorenzo River tributary to Pacific ocean to be diverted in Sec. 12, T 11 S, R 2 W, for municipal purposes to supply City of Santa Cruz and adjoining area.

Application No. 5217 (Sonoma County)—G. D. Smith, Rio Nido, Calif., for 1.5 cubic feet per second from 2 unnamed streams tributary to Russian River to be diverted in Sec. 26, T 8 N, R 10 W, for irrigation purposes on 45 acres in Sec. 26. Estimated cost $10,000.

Application No. 5219 (San Mateo County)—Cuesta-La Honda Co., 212 Sutter St., San Francisco, Calif., for 0.25 cubic foot per second from Mindego Creek tributary to Alpine and San Gabriel Creeks to be diverted in Sec. 13, T 7 S, R 4 W, M. D. M. for domestic, lawn and garden purposes on 100 acres. Estimated cost $10,000.

Application No. 5222 (Sutter County)—Judah Boas Finance Corporation, 454 Montgomery St., San Francisco, Calif., for 40.00 cubic feet per second from Sacramento River tributary to Suisun Bay to be diverted in Sec. 23, T 13 N, R 2 E, M. D. M., for agricultural purposes for the irrigation of 1600 acres of rice. Estimated cost: Already completed.

Permits Issued

Among the more important permits to appropriate water issued by the Department of Public Works Division of Water Rights, California, during the month of September, 1926, were the following:

Permit No. 2609, Application No. 5100 (Sutter County) Issued to Steve M. Burtis, Meridian, Calif., September 7, 1926 for .83 cubic feet per second from Sacramento River in Sec. 24, T. 15 N, R 1 W, for irrigation of 66.41 acres in Sec. 24. Estimated cost $500.

Permit No. 2610, Application No. 5047 (San Joaquin County) Issued to Mrs. Louisa Stark, Stockton, Calif., Sept. 8, 1926, for 16.66 cubic feet per second from Salmon Slough and Middle River in Secs. 23, 35, 27, T. 1 S, R 5 E, for irrigation of 1334.8 acres near points of diversion. Estimated cost $10,000.

Permit No. 2615, Application No. 4898 (Butte County) Issued to Henry D. & Edward Gage, Chico, Calif., Sept. 13, 1926, for 8 cubic feet per second from Cherokee Slough in Secsfl 22 and 11, T 19 N, R 2 E, for irrigation of 720 acres near point of diversion.

Permit No. 2618, Application No. 5099 (San Bernardino County) Issued to U. S. Forest Service, San Bernardino, Calif., Sept. 20, 1926, for .35 cubic feet per second from 4 unnamed springs in Secs. 24, 25, 26, 36, T 2 N, R 2 W, for domestic purposes on 214 lots. Estimated cost $10,000.

Permit No. 2619, Application No. 5014 (Santa Barbara County) Issued to F. W. Matthiessen, Triunfo, Calif., Sept. 21, 1926, for 1.25 cubic feet per second from Hot Springs Creek in Sec. 11, T 5 N, R 29 W, for domestic and irrigation of 230 acres near point of diversion.

Permit No. 2623, Application No. 5015 (Plumas County) Issued to F. F. Ford (Trustee-for Lott's Lake Ass'n) c/o R. M. Gray, Oroville, Calif., Sept. 23, 1926, for .002 cubic feet per second from unnamed spring in Sec. 15, T. 25 N, R 5 E, for do-

mestic purposes in Sec. 15. Estimated cost $500.

Permit No. 2626, Application No. 4883 (San Bernardino County) Issued to Fisher C. Bailey, Beverly Hills, Calif., Sept. 24, 1926, for .10 cubic feet per second from spring and unnamed creek in Sec. 17, T 2 N, R 1 W, for domestic and irrigation of 10 acres near point of diversion. Estimated cost $4000.

Permit No. 2627, Application No. 4884 (San Bernardino County) Issued to Fisher C. Bailey, Beverly Hills, Calif., Sept. 24, 1926, for .15 cubic feet per second from 2 unnamed streams in Sec. 17, T 2 N, R 1 W, for domestic and irrigation of 12 acres near point of diversion. Estimated cost $4000.

Permit No. 2629, Application No. 5003 (Siskiyou County) Issued to Morgan A. Gunst, 601 3rd St., San Francisco, Calif., Sept. 27, 1926, for 808 gallons per day from unnamed spring in Sec. 24, T 47 N, R 6 W, for domestic and irrigation of 10 acres in Sec. 25. Estimated cost $1000.

Permit No. 2630, Application No. 4681 (Yuba and Nevada Counties) Issued to Dry Creek Irrigation Dist., Wheatland, Calif., Sept. 28, 1926, for 13,798 acre feet per annum from Dry Creek in Secs. 32 and 35, T 15 N, R 6 E, for irrigation of 4000 acres and stock watering within said district. Estimated cost $300,000.

Permit No. 2631, Application No. 2270 (El Dorado County) Issued to El Dorado Irrigation Dist., Placerville, Calif., Sept. 30, 1926, for 150 cubic feet per second and 29,000 and 7000 acre feet from N. Fork Cosumnes River, Camp Creek and Sly Park Creek in Secs. 4 and 10, T 9 N, R 14 E, Secs. 24 and 9, T 10 N, R 13 E, and Sec. 25 T 10 N, R 14 E, for irrigation of 30,702 acres within El Dorado Irrigation Dist. Estimated cost $1,030,000.

OREGON

Among the more important applications for permit to appropriate water filed in the office of Rhea Luper State Engineer of Oregon, Sept. 4 to Oct. 9, 1926, inclusive, were the following:

S. N. Belton of Burns, covering the appropriation of underground water for irrigation of 232.26 acres in Harney County, at a cost of $4500.00.

Arthur C. Keene of Heppner, covering the appropriation of water from Rhea Creek for irrigation of 32 acres in Morrow County.

J. I. Hall of Myrtle Creek, covering the appropriation of water from Myrtle Creek for irrigation of 15 acres in Douglas County.

C. E. Hoyt of Fort Klamath, covering the appropriation of water from Wood River for irrigation of 8 acres in Klamath County.

Arnold Irrigation Company of Bend, covering the construction of the Arnold Crane Prairie Reservoir for storage of 120,000 acre feet of water from West Fork Deschutes River and tributaries for irrigation, power and domestic purposes in Deschutes County. at a cost of $200,000.

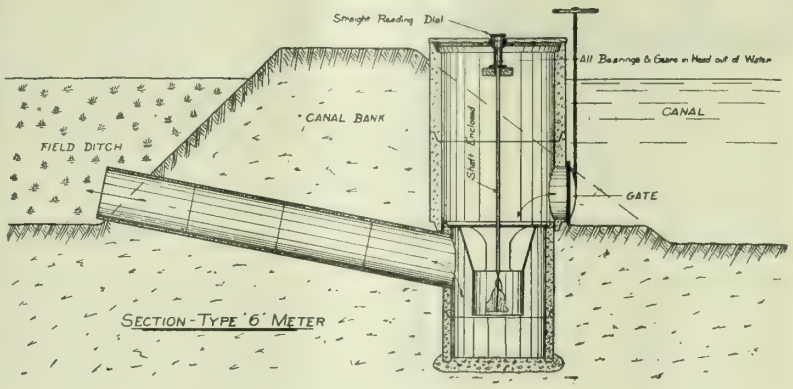
Carl Ober of Tygh Valley, covering the appropriation of water from White River for irrigation of 20 acres in Wasco County.

Laura Elliott of Elgin, covering an appropriation of water from Clark's Creek, for irrigation of 40 acres, at an estimated cost of $100.

Nick Barry of Adel, Lake Co., covering an appropriation of water from Jack Creek tributary to Guano Lake for storage for irrigation at an estimated cost of some thousands of dollars.

Albert S. Brown of Grants Pass, covering an appropriation of water from springs on

The RELIANCE METER



THE "Type 6" Reliance Irrigation Meter offers you standardized permanent construction at a very low first cost. Their sustained efficiency with a minimum of upkeep has been proven by 12 years usage. Cut shows installation of the 4 sec. ft. size in 24 and 30-inch concrete pipe. This is the standard type of setting adopted by many irrigation districts in Texas and elsewhere who are now equipping all their deliveries with this device. The "Type 6" meter is furnished in sizes ranging from ½ up to 16 sec. ft.

Sexten Mountain for irrigation of 10 acres, at an estimated cost of $200.

B. M. Porden of Portland, covering an appropriation of water from Poison Slough in Marney County for irrifiation of 100 acres.

Louis Keil of Aurora, covering an appropriation of water from unnamed tributary of Willamette River in Clackamas County, for domestic use and irrigation of 2 acres, at an estimated cost of $500.

Louis Miller and Geo. A. Grieve of Hornbrook, covering an appropriation of water from Jenny Creek in Jackson Co. for irrigation of 57 acres, at an estimated cost of $1000.

"Winning of the West" League Answer to Hoover's Plea

(*Continued from Page 18*)

der Dam project as recommended by the committee of engineers, and said that the sale of water and power wholesale to municipalities and large organizations would pay off the entire project in 25 years.

The Boulder Dam project was opposed by State Senator Fred T. Colter, president of the Arizona High-Line Reclamation Association, who urged as a substitute the construction of dams across Glen and Bridge Canyons, and a high-line canal, diverting water by gravity to irrigate 3,500,000 acres of land in Arizona and to develop power that would more than pay for the whole project.

State Senator Charles P. Squires, of Las Vegas, Nevada, who had taken part in more official conferences on the Colorado River than any other delegate present, declared that an agreement could be reached that would be fair to Arizona, California and Nevada. He said that the problem should be approached in a statesman-like manner and not with petty interests dominating.

New Mexico's View

Dr. H. L. Kent, president of the New Mexico Agricultural College, spoke of the problems of New Mexico and western Texas. He described the Rio Grande and spoke of the necessity for water storage along the Pecos River.

The situation in the Sacramento-San Joaquin Valleys was forcefully presented by Ben M. Maddox, of Visalia, member of the California State Irrigation Association. He stated that they had water enough to irrigate eighteen million acres if it were conserved, and said that the greatest problem was to get the facts before the people. "The state has spent $250,000 to get a report on our water resources," he said, "and how many of you have ever even read this report?"

The necessity for preserving the forests was brought out by Congressman A. M. Free, of San Jose, California. The water originates in the forest water sheds, he explained. As the forests are allowed to burn, the floods become more disastrous and the ensuing scarcity of water more acute. In 1924, according to Mr. Free, there were 162 forest fires in Southern California, burning 154,000 acres of government land and 20,000 acres of private land. It cost the government $375,000 to put out these fires, as against $9,000 that had been appropriated for fire prevention.

Committee Formed

Organization of the "Winning the West" League was through a resolution introduced by Arthur E. Miot, secretary of the Tulare County Board of Trade, declaring approval of the principles set forth by Hoover, and calling for the appointment of a committee to confer with him regarding the procedure to be followed. Thomas E. Campbell, as chairman of this committee, appointed the following members as co-workers:

John L. Bacon, mayor of San Diego and president of the Bouder Dam Association; Shirley C. Ward, member of the power and reclamation committee of the Los Angeles Chamber of Commerce; Hervey Lindley, of Seattle, president of the Columbia Basin League; I. E. Vining, of Portland, president of the Oregon State Chamber of Commerce; Fred Farrar, Chamber of Commerce, Denver; Charles P. Squires, Las Vegas, Nevada; Dr. H. L. Kent, president of the New Mexico Agricultural College; W. F. Jensen, Salt Lake City, personal representative of Governor Dern, of Utah.

Secretary Hoover is expected to arrive in Los Angeles on October 30, and the committee, representing the "Winning of the West" League, will then discuss with him the first steps to be taken in making the league an active force in the development of water resources throughout the country.

Legal and Judicial News

(*Continued from Page 88*)

ling element, the character of the tax, is the same in each case; hence the rule is the same."

This case once again brings up the question as to whether irrigation district assessments are general or special liens. Outside of Colorado it would appear that the generally accepted theory was that such assessments are general liens.

Water Right and Right of Service Distinguished

Under Washington Statutes a water right does not come under the control of the Public Service Commission.

In the case of Ament vs. Bickford 247 Pac. Rep. 952 (July 14th, 1926) the predecessor in title of respondent, in 1912, sold to the predecessor in title of the appellant, a parcel of land. Coincidently and according to the contract of sale, "as a part of the consideration of said purchase price and as a contract run-

ning with the land" the respondent conveyed a perpetual right to . . . water . . . and appellant agreed to pay annually a definite amount for the use of the water system from which the water originated. After many years of observance of the contract . . . the respondent interfered with the appellant's rights and destroyed the water connections and shut off the supply.

A demurrer to the complaint was sustained by the trial court.

Among the points made by respondent in support of the Trial Court's Order was that the contract was void and unenforceable for the reason that the water owned by the grantor was subject to regulation by the Public Service Commission. On this point the Supreme Court of Washington states:

"No merit is found in this claim, for the purchase was not of water from a water system, but of a certain definite water right. If the respondent's theory was correct, every owner of a water right in the State might be subject to regulation by the Public Service Commission."

Irrigating Vegetable Crops

(*Continued from Page 92*)

(1) Weed seeds germinate in large quantities and weeds are killed in wholesale fashion prior to planting, thus reducing the amount of hand labor and damage from volunteer growth during the growing season.

(2) Organic matter is decomposed more rapidly and with less loss of nitrogen.

(3) Action of beneficial bacteria is started earlier.

(4) Beds hold up better if made of moist soil.

(5) The first furrow irrigations are more rapid and thus less expensive.

(6) If the irrigation shows irregularities in the land it is sometimes still possible to correct them before planting time.

Not An Essential Practice

In spite of the fact, however, that there are some decided advantages in this preliminary irrigation it has been demonstrated repeatedly that it is not strictly necessary. Unless this irrigation can be given early enough to permit final preparations for planting at the proper time it should be omitted.

In preparing for flooding, the land is floated and borders are thrown up to make checks. These borders may be made with plows, bordering disks, or special bordering tools, one of which is built with planks standing on edge and converging at the rear.

In some cases seed beds are made in land which has not received a preliminary flooding and the beds are wet before planting by running water in the furrows. The water is allowed to sub thoroughly through the beds so that it finally moistens the entire beds.

Irrigation When Planting

In arid or semi-arid localities such as Imperial, Salt River, Snake River, and even San Joaquin valleys, it is the customary practice with some crops at least to irrigate in furrows as soon after planting as it is desired to bring up the crop. The beds are irrigated continuously until germination takes place and the small plants appear above ground. In some instances this irrigation follows planting immediately but this is not always the case.

If the stand of plants is not satisfactory some times another irrigation is given to germinate more seed. In some cases an irrigation after thinning is desirable as it supplies abundant moisture at this critical time.

Crops which are commonly transplanted, such as cauliflower, cabbage, tomatoes, celery, etc., are usually irrigated immediately after being set in the field. As soon as possible each row is irrigated by turning water down the furrow.

Encourage Deep Root System

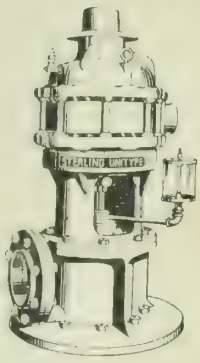
As a rule, however, irrigation during the early stages of growth should be practiced with caution. A deep root system should be encouraged and this will not form when there is an abundance of moisture near the surface. Moreover the young plants with a very limited leaf surface do not require large amounts of moisture particularly during the cooler portions of the year. With cantaloupes, tomatoes, and potatoes, especially, a deep root system is recognized as highly desirable and sometimes several weeks are allowed to pass without irrigating in order to assure deep penetration of the roots.

Yet in endeavoring to promote a good root system one should not go to extremes. A sturdy deep-rooted plant is undoubtedly better than one which is sappy, tender, and supported largely by surface feeders, yet caution should be exercised by the grower in order to avoid injury which might occur under certain conditions. If there is any doubt in the grower's mind as to the moisture content of the sub-surface soil, he should investigate in different portions of the field to determine to his own satisfaction that ample moisture is available. With potatoes there should be a very favorable moisture situation at setting time if a liberal set per hill is desired.

Sometimes it is advisable to irrigate in advance of the time the plants appear to actually need more water. This is true when water cannot always be had at the desired time, or where the fields are so large that it is impossible to get over them soon enough if the start is deferred until the last minute.

Sterling Quality CENTRIFUGAL PUMPS

VERTICAL PUMPS for Surface or Pit Pumping. Same construction features as the split case Centrifugal Pump. Sizes—1½ in., 2 in., 3 in., 4 in., 5 in., 6 in., & 8 in. Send for bulletin No. 21.



Sterling Unitype Drive
The Original

Deep Well Turbine Pumps

Made for the following well diams.: 4 in., 6 in., 7 in., 8 in., 10 in., 12 in., 14 in., 16 in., 18 in. and 20 in. Capacities 20 G.P.M. to 4,000 G.P.M. Send for Bulletin No. 16.

NOTE—The motor drive for this vertical pump interchanges with the deep well Turbine Drive.

AMONG OUR CONTRIBUTORS

Editorial Jottings About Current and Forthcoming Feature Articles; Dealing With Practical Problems of Hydraulics, and the Men Who Have Written Them

HARLOWE M. STAFFORD, water supervisor for the Sacramento and San Joaquin Rivers, and associate hydraulic engineer of the California Division of Water Rights, is the author of the informing article which presents the highlights of the dramatic situation in which water users of these rivers are being forced into the most rigid forms of conservation in order to keep a flow ever going into the sea.

Mr. Stafford was educated in California schools and received his B. S. degree in engineering from the University of California. His early experience was with the U. S. Geological Survey, followed by service with the Anderson-Cottonwood Irrigation District, as office engineer; and a term of service in charge of rice irrigation experiments for the U. S. Department of Agriculture.

In 1918 he became office engineer and resident engineer on construction for the Happy Valley Irrigation District, and in 1920 was called to similar duties for the Corcoran Irrigation District. The following year he became identified with the state Division of Water Rights, with which he has been connected in various capacities, first in field investigations, inspections and reports, and since 1924 in the important position which he now holds.

CHARLES H. LEE, writer of the comprehensive "Water Survey of San Francisco District," is a consulting engineer in private practice in San Francisco, specializing in water supply and development.

Mr. Lee graduated from the College of Civil Engineering, University of California, in 1905. From 1906 to 1912 he was associated with William Mulholland in the work on the Los Angeles aqueduct. During 1912 he was assistant engineer of the State Conservation Commission of California, investigating underground water conditions and water spreading in Southern California. He then engaged in private practice in Los Angeles, giving special attention to hydro-electric power, irrigation, and public water supply.

With the entrance of the United States in the World War, Mr. Lee went with the American Expeditionary Forces to France, where he served as first lieutenant and captain, planning and installing water developments along the lines of communication and on the active

Harlowe M. Stafford

front. On his return to California in 1919 he became an executive member and president of the California State Water Commission, and later chief of Division of Water Rights, State Department of Public Works. Since 1922 Mr. Lee has been engaged in private practice.

FRED A. RHODES, who prepared the illuminating discussion of the water situation in San Diego and the city's plans for the future, is city manager of San Diego. Mr. Rhodes has been the main factor in working out the plans for water development and in securing their adoption, and has just directed the water bond election for an issue of $2,000,000 that went over twelve to one.

R. G. RISSER, who writes on "Keeping out of the Red with Vegetables," has been for the past seven years manager of the crop production department of the California Vegetable Union. Before entering upon his present work, Mr. Risser was for several years connected with the United States Department of Agriculture, as a specialist in irrigated vegetable crops. He is the author of a number of articles on various phases of vegetable growing.

ADOLF H. KOEBIG, JR., who contributes the feature article for the Sewage Disposal department of WESTERN WATERWORKS, has had a wide contact with the irrigation and allied hydraulic industries. His technical training was received at Stanford University and Amherst College, where he majored in civil engineering, after which he was connected with the good roads department of Los Angeles County, California. Later he went with the Los Angeles County construction department as supervising engineer of re-enforced concrete buildings.

Following a varied experience in the building trades, Mr. Koebig then became associated with his father, Adolf H. Koebig, of Koebig and Koebig, Los Angeles, one of the pioneer engineers of the west, who has figured prominently in the designing and construction of many of the major hydraulic projects of California and other western states. With Koebig and Koebig (as the firm later became known), his first work consisted of field investigations. In a short time he became supervising engineer on several important irrigation, drainage, sewerage, and hydro-electric projects, and was made junior partner.

While Mr. Koebig's work has been in various engineering fields, he is regarded as an authority on sewerage construction. The new sewage disposal system at El Segundo, as described in this issue of WESTERN WATERWORKS, has attracted wide interest among municipal and sanitation engineers and we feel fortunate in being able to secure the first publication of an article upon this most interesting installation.

The Progress of Irrigation

WITH the close of the year only a little more than a month away it seems fitting to review agricultural conditions on the irrigation projects of the Bureau of Reclamation. Crop information on these projects is in such form that it is possible to collate it and thereby obtain a panorama of the irrigated crop situation generally. Conditions at the close of October on the various projects were as follows:

Yuma project, Ariz.-Calif.—Planting of 2,500 acres of lettuce was nearly completed and the crop was coming up very satisfactorily. The new crop of alfalfa hay was very good and the market had improved $3 to $4 a ton. Cotton picking continued and excellent yields were anticipated. About 16,000 bales had been ginned at the end of the month, compared with 13,600 bales at the same date last year. The citrus fruit crop on the Mesa will amount to about 4,000 boxes. During the month 341 carloads of agricultural products valued at $490,600 were shipped from the project, making a total since the first of the year of 2,669 carloads valued at $2,630,000.

Orland project, Calif.—Most of the cotton had been picked during the month, with a yield about the same as last year. The price, however, was so low as to make the crop unprofitable. The fifth crop of alfalfa was cut. Olive picking was in progress. Preparations were being made by the Orland Orange Growers' Association to begin packing the crop during November.

Grand Valley project, Colo.—Alfalfa produced a good yield of excellent quality, but the market was limited and prices were low. The tomato harvest extended longer than normal and excellent yields were promised. Good crops of apples and pears were grown, but prices were unsatisfactory. Poor yields were reported for potatoes, beans, and sugar beets.

Uncompahgre project, Colo.—Reduced yields were reported for the principal money crops, namely, potatoes, onions, and beets. The price of potatoes ranged around $1.90 per hundredweight, but much of the crop was being stored for higher prices. Most of the onion crop was also going into storage.

Boise project, Idaho—Picking and packing of fruit were completed during the month, and threshing was practically finished. Hay was selling from $7 to $8 a ton with little demand.

Minidoka project, Idaho—The yield of

"Western Waterworks" Begins on Page 25

potatoes was better than expected and prices advanced from $1.50 to $2 per hundredweight at the end of the month. Harvesting of this crop was completed and 552 carloads were shipped from project towns. A large portion of the crop was stored. Clover seed yielded well and commanded good prices.

Huntley project, Mont.—Harvesting of the beet crop was completed during the month and yields were invariably excellent. Several growers reported total yields of more than 1,000 tons each.

Milk River project, Mont.—Harvesting of all crops was practically completed. The sugar beet yield was very satisfactory. On the Malta division several fields yielded more than 15 tons per acre. On the Chinook division the maximum reported yield was 26 tons per acre. A considerable increase in the acreage of this crop is expected next season. Two carloads of certified seed potatoes were shipped to southern markets and about 12 more carloads will be forwarded later. The average yield of this crop was reported to be about 350 bushels per acre.

Initial furrow irrigation of celery immediately following transplanting in Southern California

Sun River project, Mont.—Threshing of small grain was completed. Sugar beets will yield about 12 tons per acre. Good yields of potatoes were obtained and satisfactory prices prevailed. Considerable fall plowing had been done. As a result of favorable crop conditions and prices there was a much better feeling among the farmers on both divisions.

Lower Yellowstone project, Mont.-N. Dak.—All crops had been harvested and good yields were reported. A water user at Fairview produced $800 worth of cabbages on 1¼ acres, or at the rate of $600 an acre.

North Platte project, Nebr.-Wyo.—The potato harvest was completed and about 85 per cent of the beets were out of the ground. The reduced yield of potatoes owing to frost was offset by the favorable price. The yield of sugar beets will be about 25 per cent less than the record crop of 1925.

Newlands project, Nev.—There will probably be no surplus alfalfa this year as large shipments of feeder cattle are coming to the project from Idaho. Contracts for sugar beet acreage were being signed and the Fallon Sugar Company states that the factory will operate in 1927.

Carlsbad project, N. Mex.—At the close of the month 5,500 bales of cotton had been ginned. The prevailing price of good grade cotton was around 13 cents at the end of the month.

Rio Grande project, N. Mex.-Tex.—Cotton ginning was considerably delayed by wet weather. The price ranged around 14 cents a pound. Alfalfa was selling for about $15 a ton.

Klamath project, Ore.-Calif.—Harvesting of crops had been completed with the exception of potatoes, of which about 75 per cent had been dug. Excellent yields of this crop were reported and about 200 carloads had been shipped.

Belle Fourche project, S. Dak.—Harvesting of sugar beets continued and about 85 per cent of the crop had been delivered at the dumps. About 400 carloads had been shipped from the dumps and about 225 cars remained in huge piles at Nisland and Fruitdale. The yield will average 14 tons per acre with some growers reporting 18 to 20 tons. Picking corn was in progress. About half the crop was being harvested by sheep and hogs. Yields were excellent.

Yakima project, Wash.—In spite of the heavy drop of apples following the frost late in September, the crop appeared to be the largest in the history of the project. The entire crop had been harvested and warehouses were packed to capacity. Owing to low prices, however, the profit to the growers will be small. Shipments of apples exceeded those of October 30 of last year by 2,359 cars. The total fruit shipments from the valley amounted to 12,691 cars and vegetables to 4,175 cars. This is 1,122 cars in excess of the number shipped up to the same date last year. The potato crop was reduced about 20 per cent, but the demand was heavy.

"Western Waterworks" Begins on Page 25

This is Lake Henshaw, from which the Vista Irrigation District draws the water to supply 14,600 acres of land, the allocation of which, within the district, called forth an unusual and ingenious legal expedient, described in the accompanying article.

How the Vista Irrigation District Solves Its Complex Riddle of Water Allocation

By GEORGE S. HENRY

Presient, Vista Irrigation District, California

ALLOCATION OF WATER in an irrigation district which embraces lands of varying character and water requirements is one of the most perplexing practical problems facing the district manager. The particular section of the statutes governing the matter is closely correlated with that of land valuation for assessment purposes, which gives rise to much confusion in attempting to reconcile theory with practice. This problem of water allocation was met in an ingenious manner by the Vista Irrigation District of San Diego County, California.

The water supply for the Vista district is obtained from Lake Henshaw on the upper San Luis Rey River under a perpetual purchase contract with the San Diego County Water Company. The amount is definitely fixed at 13,600 acre feet* per annum at the end of ten years, through annual increments of 10 per cent during the interval, designed to permit of progressive development and colonization of the lands without excessive burden of charges for water service meanwhile.

The territory embraced within the district aggregates 17,600 acres and is generally rolling, of varying soil types and character, with some broken untillable land. No classification of the lands was made when the boundaries of the district were fixed, but it was assumed that 60 per cent would be irrigable and tillable.

Before sanction of a bond issue could be secured from the Bond Certificate Commission which has jurisdiction in California, the then State Engineer, W. S. McClure, ruled that, as a prerequisite, the water supply should be definitely limited to a duty of one acre foot per gross acre of land. In other words, the 13,600 acre feet of water then contracted for should be allocated to no more than 13,600 *gross* acres of land.

Since statistics have shown that from 15 per cent to 25 per cent of any irrigation project fails to use water from year to year, this requirement was intended to give an available average of from 1.15 to 1.25 acre feet per net irrigated acre. This duty of water in the district may appear high, but conditions are extremely favorable at Vista and experience is proving it conservative. To comply with the state engineer's requirement necessitated either disorganizing the district and reorganizing to embrace an acreage corresponding to the formula for water supply, or the exclusion of about 4000 acres. The latter alternative could be accomplished only through consent of the owners, since there is no power in the board of directors to force such withdrawal.

But either of these two methods presented insurmountable obstacles, and finally a novel and hitherto untried solution was evolved. The statute permits an owner of land in an irrigation district to *assign his right* to the use of the water allocated to his property to others within the district. Taking advantage of the provision, Senator Leroy A. Wright, attorney for the district, formulated an assignment or waiver whereby, for a mutual consideration, the land owner assigned to the district *in perpetuity his right to demand water* for a

*Since the original contract was made, the district has acquired from the water company 1,000 acre feet per annum on a straight delivery basis.

"Western Waterworks" Begins on Page 25

specified and legally described portion of his land. This procedure was given close scrutiny by the ablest irrigation attorneys in the state and was favorably endorsed.

Putting It Into Effect

Promptly thereafter the board of directors appointed a land classification committee, composed of men of experience and standing in the locality, aided by several outsiders, and a careful classification of the lands of the entire district was made, and such areas as, in the judgment of this committee, because of character of soil or topography or being otherwise unworthy of irrigation, were "declassed." Where possible, as was the case generally, the land owner accompanied the committee and his assent to the "declassification" was obtained on the ground.

An engineering crew then traversed the areas so "declassed" and prepared legal descriptions, using government subdivisions as far as possible by slight shifting of meander courses; otherwise by straight metes and bounds. These descriptions were then incorporated in the assignment or "waiver," duly executed and acknowledged before a notary by the owner and held for recording at the proper time.

It so developed that the aggregate area covered by these assignments, plus a few exclusions of lands on the exterior boundaries of the district, effected a reduction of irrigable acreage to an exact agreement with the water supply requirements. These assignments were then placed on record. Certificates of title covering land within the Vista district now make note of the fact of the assignment or waiver of *right to demand* water on these specified areas, which is notice to subsequent purchasers of the status of such lands. These areas are generally termed "waived lands" throughout the district, and while at first some confusion existed as to their status, that has rapidly cleared up and their utility is being realized as will further appear.

The district subsequently procured an additional 1,000 acre-feet of water and released the assignments or waivers on one thousand acres of "waived lands," so that the present water supply is 14,600 acre-feet. The result of the foregoing procedure is that the water supply of 14,600 acres is definitely allocated to 14,600 acres of land having so-called "full water rights."

"Toll and Assessment" Plan

The district has adopted a combined "toll and assessment" plan to meet its budget, which is particularly practicable and feasible because of the purchase of its water on a metered basis for a predetermined amount. A budget is prepared to cover solely estimated maintenance and operation costs, and accruing bond interest for the ensuing fiscal year. The assessor fixes the valuation of the lands within the district on a carefully zoned and balanced scale of values ranging from $135 minimum to about $300 per acre on irrigable land with "full water rights," except for town lot sub-divisions which aggregate somewhat higher on acreage basis.

The "waived" lands are valued at from $1.50 to $5.00 per acre, the intention being to eliminate as nearly as possible all tax burden on lands so divested

(*Continued on Page 36*)

Washington State College, Pullman, Washington, an institution that has played an important part in the development of irrigation in the Northwest.

"The Farmer Can Not Afford to Experiment—The College Must Do It for Him"

Says O. L. WALLER

In Describing the Services that Washington State College Has Rendered to Irrigation—Another of MODERN IRRIGATION Articles Devoted to the Function of the Colleges in Hydraulic Progress

IN 1900, the State College of Washington co-operated with the United States Department of Agriculture under the direction of Dr. Elwood Mead, then Chief of Irrigation Investigations for the United States Department of Agriculture, in making a study of the duty of water in the Yakima Valley. This early work consisted in trying to find out how much water the farmers were accustomed to use for growing crops. One season was devoted to determining the co-efficient of friction in irrigation canals. At that time the college had no definite experiment station and made the duty of water studies in co-operation with farmers who were willing to apply the water on certain plants as directed, and on others as they were accustomed to apply it. Some very good results were secured, particularly in connection with the irrigation of potatoes. One set of tests showed that about eighteen inches of irrigation water per acre gave the highest starch content in potatoes, and the highest yield of marketable potatoes.

While no direct experimenting was carried on for a number of years after this, much help was offered to the farmers in the irrigation districts by the faculty of the college, both in engineering and in agriculture. In 1909, the writer prepared a bulletin for the U. S. Department of Agriculture on "Irrigation in the State of Washington." The bulletin was written to supply a demand for information concerning irrigated agriculture in Washington.

Conflict in Doctrines

The water-right laws of Washington were built upon the English doctrine of riparian rights, supplemented by a statute providing that water might be appropriated. These two doctrines were in direct conflict, and were the source of much trouble in the irrigated districts. The streams of the state had been very much over-appropriated and water-right conflicts were frequent. There was no way by which one could know how much water his land was entitled to, and he did not know how much he would be protected in the use of. It was apparent that all water-rights in the state should be determined and titles set at rest so that an abstract of title would cover water rights as well as the land upon which it was used. In 1904, Governor Henry McBride appointed an irrigation commission to draft a water code for the state. This commission reported to the following legislature but their recommendations failed to become law. On this commission Washington State College was represented in the person of its president, E. A. Bryan.

Shortly after the National Irrigation Congress met in Spokane in 1909, Governor M. E. Hay appointed a commission to draft a water code for the state. The writer was chairman of this commission. A water code, closely following that of Wyoming and Oregon, was drafted, was printed and went to the legislature for consideration but failed to become a law.

Third Commission Tries

Governor Ernest Lister appointed a third commission consisting of seventeen members, to try to draft a water code that would be satisfactory to the state legislature. Again the chairmanship was given to the State College. This bill was printed and presented to two sessions of the legislature and finally, in 1917, was adopted. Under the provisions of this bill, water rights may be adjudicated by the Supervisor of Hydraulics, subject to appeal to the courts.

"Western Waterworks" Begins on Page 25

The plan is very effective and titles are secured at a minimum of cost. The enactment of this law has meant very much to the state since it is now possible for anyone using water for irrigation or power to have his rights completely defined and set apart for a particular use.

Branch Authorized

In 1917, the legislature authorized the establishment of an irrigation branch station for the purpose of studying the principles and practices of irrigation agriculture. A committee of five men, experienced in irrigation and agriculture, were detailed to make a selection of land for an experiment station. A number of sites were examined, and one at Prosser, Washington, was finally selected. This station covers a variety of soils from light sandy soil to a silt loam. Upon it can be found almost any type of soil that is now used for irrigation purposes anywhere in the state. A location having on it such a variety of soils makes it possible to carry on experiments fitting the various types of irrigated lands in the State.

Irrigation is an artificial way of supplying moisture to growing crops. The amount of water to be used and the time when it is to be applied are under the control of the farmer. He, therefore, needs information concerning the water holding capacity of the soil so that he may know how much water to apply at an irrigation, to the end that there may be a minimum of leaching into the sub-soil and that waste of water and fertilizer may be avoided. The farmer wants to know what crops are best adapted to his climate and soil. He also wants to know when to irrigate and how much water to apply at an irrigation.

Water a Measured Service?

Sometime, not far in the future, water will be sold by quantity as other commodities are sold and then the irrigator will want to get the maximum return for the money spent for an acre-foot of water. It is the purpose of the irrigation station to show how this may be done. To get the best return from the irrigated farm, the farmer must plant the right kind of crops and the right varieties; he should know when to irrigate and how much water to apply at an irrigation. He needs information with reference to the different types of soil so that he may adopt the right procedure for the several types of soils found on his farm. He will need to know the relationship between the yields, the amount of water applied, the number of irrigations, the intervals between irrigations and the moisture content of the soil throughout the growing season.

The irrigation experiment station at Prosser is now studying the application of water to alfalfa at different time intervals. A series of "water relation experiments" is being conducted to furnish information relative to the amount of water needed at an irrigation. A very important study is under way to determine the field soil water holding capacity of the various types of soils. This will show the amount of moisture before and after irrigation in the first six feet of soil, and so far has shown that the water holding capacity of the soil, 24 to 48 hours after irrigation, as determined by an average of all samples, was 2.77 inches for the first foot, 3.52 inches for the second foot, and 3.27 inches for the third foot.

O. L. WALLER

Professor Waller, who has written the accompanying article on the service to irrigation of Washington State College, is vice-president of that institution, and head of its department of civil engineering. A more complete outline of his career appears in our Contributors' Department.

Tests Are Significant

The soil under test showed a water holding capacity of three and one-half inches of water per foot when saturated in the field, and two and one-half inches under conditions of equilibrium after being thoroughly irrigated. This means that the upper six feet of soil will hold fifteen acre inches of water before there is any loss due to deep percolation. This shows a considerable storage capacity in the soil itself. The experiments further showed that one-half inch of water per foot was necessary to have any available water for the crop plants.

In a number of places in the state for late fall and early spring irrigation, considerable water is available if it could be stored in the soil itself, but in some cases the expense of storage in reservoirs would preclude its use.

Fall and Spring Tests

The station is at work on a series of experiments to determine the effect of fall and spring irrigation upon crops. The fall and spring irrigation of alfalfa and corn has been carried on for several years. In 1925, the alfalfa yields did not show a noticeable increase or decrease due to fall irrigation. The corn plats, however, were irrigated in the spring before planting and showed an increase of 11.7 bushels per acre over the average of the plats that were fall irrigated.

These experiments will be continued on different types of soil to get information that will be useful to projects wishing to store winter and spring run-off in the soil that is to be cropped the following season. Such experiments should be valuable in the development of a considerable acreage of land that is now not irrigated, which could be irrigated from the late fall and spring run-off from adjoining streams.

Some demonstrations are needed to teach the farmer what amount of soil moisture is needed at all times to provide for the most thrifty growth.

Better Results Expected

The several types of soil at the Prosser experiment station make possible such a study and demonstration. There is a big difference between the amount of water on a saturated soil from which the air has been driven out and the plants are stunted and one that is so dry that the plants are wilting. These two extremes are frequently seen but always to the detriment of the growing crop. Somewhere between these two extremes there is a quantity of irrigation water which will produce the largest marketable yields and here is where the experiment station can render a very great service. The farmer cannot afford to experiment but the station can. It should not only gather such information but should teach the farmer how to use it.

Some simple method of determining the proper amount of water required for the best yield is much needed; a method that the farmer himself can use in determining the amount of water needed by the crop, on any type of soil. If the beginner in irrigation could have such information and be advised as to the crops adapted to his lands and climate, many failures would be avoided.

Relation of Depth of Water Used and Density of Population, California Cities of 8,000 or More Population.

Area used as Common Factor in Estimating Water Needs of Cities

By CHARLES H. LEE

*Consulting Hydraulic Engineer, San Francisco**

PERHAPS the most complex of all water consumption problems which waterworks officials and engineers are called upon to answer, is the future water requirement of metropolitan areas. Such areas will always be composed of distinctive units, some urban or suburban residential, some commercial or industrial, and some rural or recreational. Each will have different water requirements, the amount of which in many cases will be wholly unrelated to the number of individuals resident upon such areas.

This problem has already come to the front in California in the metropolitan districts of Los Angeles and San Francisco-Oakland, and will later arise in the metropolitan areas which are beginning to surround San Diego and other rapidly growing cities. Recreational areas such as those about Monterey Bay and Santa Barbara also have this problem to meet.

There has thus arisen a definite need for some simple basis of estimating, other than population, which can be applied to all varieties of use and yet be related to some common factor. The problem has presented itself to the writer on several occasions and much thought has been given to it.

Solution Proposed

As a solution, it is proposed to use area as the common factor instead of population, with equivalent depth of water delivered to the area as the measure of the requirement. This method has long been established in irrigation practice, the amount of water used being expressed as depth over the cropped area, the term "water requirement" or "duty of water" having come extensively into use in this connection. The area being served by a given waterworks system and the quantity of water delivered both being easily obtainable, it would seem feasible to determine the depth used per unit area, whether the use be for general municipal or for industrial or irrigation purposes.

Analysis of waterworks statistics on this basis seems not only to yield results of value for use in estimating future consumption, but also to furnish a new and useful basis for comprehensive analysis and comparison of such statistics.

The mathematical relations of per capita consumption and depth can be very easily expressed in a formula which includes population density.

If Q=total annual water consumption in gallons
C=daily per capita consumption in gallons
A=area served in acres
P=population
p=population density
D=depth of water in feet per annum consumed upon service area

$$\text{Then } D = \frac{Q}{A \times 325{,}850} = p\ C/890$$

$$\text{and } C = 890\ D/p$$

New Method Illustrated

In other words, the depth of water consumed per annum upon a given service area is directly proportional to both population density and per capita water consumption, while per capita consumption is directly proportional to depth of water consumed and inversely proportional to population density. By means of these equations, if population density is known, it is possible to convert per capita statistics into depth, and vice versa.

This paper gives the results of determinations of the depth of water used per acre per annum in general municipal service. It also illustrates a new method for analysis of water consumption data, which, it is believed, will be suggestive to both waterworks officials and the engineering profession. The writer desires to acknowledge and express his appreciation of the assistance furnished by various waterworks officials in California who were asked to furnish data. It is hoped that the paper will serve to bring forth additional information on this subject and help to stimulate the systematic reporting of the acreage of service areas.

Water Demand Statistics

The consumption of water from public waterworks systems, whether municipally or privately owned, includes both that used for domestic and public purposes, and for the needs of business and industry. It also includes loss and waste from distribution systems and service connections.

In the average American city practically all domestic water is furnished from the public supply, and as the amount depends directly upon the number of people using water, it can be readily expressed on a per capita basis. An average for the United States under modern conditions is considered to be 30 to 35 gallons per capita per day, although where garden and lawn irrigation is practiced, as in California, this amount may be considerably exceeded.

To this should be added public use for fire protection, sewer flushing, street sprinkling, parks, etc., varying from 5 to 10 gallons per capita per day in various cities. The minimum demand up-

*Except from a paper read before the annual convention California Section, American Water Works Association.

"Western Waterworks" Begins on Page 25

on any waterworks system may thus be considered as from 35 to 45 gallons per capita for the population within the service area, plus the requirements for gardens and lawns in regions where irrigation is necessary.

Industrial Demand Varies

The use of water for commercial and industrial purposes is in addition to this minimum and varies greatly in different cities, particularly that for industrial operations. This variation is due to the differences in manufacturing processes, the differing extent to which industries are established and the extent to which local sources are in use. In connection with the latter, the relative cost of water from the public system and from local sources, such as wells, is the important controlling factor.

In cities where local sources are cheaply developed and pumping plants can be operated at small cost in conjunction with other equipment, the industrial demand upon a public water system is small. On the other hand, where the public supply is furnished for industrial use at a low rate, or local sources are not available, practically all such users within the city draw from the public supply. The percentage which commercial and industrial use bears to the total is therefore extremely variable, statistics indicating a range of from 15 to 65 per cent. These facts are all well known to waterworks men, but are so pertinent to the analysis of statistics which follows that emphasis seems desirable.

General Municipal Service

Separate study has been made of the depth of water in general municipal service, and in special services such as domestic, commercial and industrial. For general service, the data available is limited to the total volume of water consumed for all purposes as contained in routine waterworks reports. The recent files of the Journal of the American Water Works Association and Municipal Index for 1925 and 1926 were extensively referred to in obtaining such information. Data for many California cities was also obtained by correspondence.

It has never become customary to report service area acreage, and such information can only be obtained by direct contact with department officials. This has been done in the case of many California cities. For other cities where data were not so obtained, the land area within municipal boundaries, as published in the latest annual reports of the U. S. Census Bureau, has been used.[1] This area does not in all cases represent waterworks service area, but it is believed to be sufficiently accurate for the purposes of this paper.

Data has been assembled for 103 typical American cities of 50,000 population and over, and for 26 California cities with a population of 8000 or more (See table 1). The data includes area and population served, total water consumption, population density, per capita consumption, and acre consumption in gallons and feet depth.

Wide Range of Demand

Preliminary study of the data showed a wide range in rate of water consumption for different cities and suggested broad classifications for detailed study, as follows:

1. *Geographical.* American cities, 50,000 or more population, and California cities 8,000 or more.
2. *Metering.* Cities 80 per cent or more metered, and those non-metered (25 per cent or less).
3. *Industrial water rates.* Cities 80 per cent or more metered with water rates for industrial use, 13 cents or more per 1000 gallons for average amounts consumed monthly, and those with rates less than 13 cents.

The method of analysis followed has been graphical. Diagrams were prepared with depth of water served over the service area in feet per annum as the vertical scale, and density of population expressed as persons per acre for the horizontal. Each plotted point represented a city, the index number corresponding to that on the tables.

Lines representing average, minimum, and maximum consumption were then drawn to conform with the plotted points. These lines pass through the zero point and their slope represents the increase of depth of water delivered for increase in population density. They can also be described in terms of per capita consumption, as is indicated by the form of the equation expressing the relation between depth, density and per capita consumption.

The position of lines equivalent to various rates of per capita consumption in gallons per day were indicated on the margin of all diagrams, thus facilitating the correlation of data when expressed either on a population or area basis. Separate diagrams were drawn for 103 American cities, and 26 California cities. The classification as to rates for metered cities was indicated on each diagram by means of conventional signs.

American Cities Metered

The total population served by the 95 typical waterworks in American cities metered is 17,829,091. The per capita daily consumption varies from 46 to 209 gallons for the various cities, and averages 95 gallons. The range of depth is from 0.1 to 4.58 feet per annum, the latter being for cities of densest population. The arrangement of the plotted points on the diagram clearly indicated the direct proportional relation between depth of water used and density of population. The average, minimum and maximum lines have the following values:

Line	Rate of depth increase per annum for each 10 persons Feet	Daily per capita consumtion Gallons
Average	1.07	95
Minimum	0.56	50
Maximum	1.68	150

It is a well recognized fact that the demand for water for industrial use is very sensitively influenced by the rates charged. When the figures for American metered cities were plotted it was discovered that cities where the industrial rate exceeds 13 cents per 1000 gallons lie below the average line, while point sat which the rate is less than 13 cents lie above. With more detailed information regarding the relative amounts of water used for various purposes, a diagram of this type would furnish an unusually comprehensive background for the comparative study of water consumption statistics in various cities.

Information regarding the characteristics of various cities, whether residential, commercial or industrial, would also be useful. For example, the normal density of population of built-up residential cities whose population is largely house in one-family dwellings, is from 8 to 10 persons per acre. This density corresponds on the diagram to a depth of approximately 1 foot per annum for average per capita water consumption.

In communities with average water consumption, if the depth of water delivered exceeds 1 foot per annum, it may be concluded either that a considerable portion of the population is living above the first floor level in flats, apartments, hotels or tenement houses, or that the commercial and industrial demand is greater than average. Both factors often act jointly to increase the depth of delivery.

Similarly, depths less than 1 foot indicate a partially built-up city or one in which industrial use is small. In a residential city it may also be indicative of the general absence of house gardens.

American Cities, Non-Metered

The relative amount of water used by eight American cities of 50,000 or more population, with small per cent of metering (25 per cent or less) was also plotted. The total population served by these cities is 13,799,000 and the average per capita consumption 167 gal-

(d) Service area for citizens numbered 1 to 18, land area; within political boundary for cities numbered 101 to 109.

lons per day. The latter is 75 per cent greater than the average for cities 80 per cent or more metered. The points in the diagram were so scattered that no attempt was made to draw an average line.

Record of California Cities

The determination of depth for California cities was made largely on the basis of service area, since, in many cases, considerable unused land was included within the municipal boundary. There being fewer points to the plot, the diagram printed herewith includes both metered and non-metered cities.

The total population served in the 26 selected cities is 3,139,785, of which 2,941,785 are in cities 80 per cent or more metered. The average per capita consumption for twenty cities of the latter class is 106 gallons daily, which is 11 per cent greater than for the 95 American cities of 50,000 and over. The maximum is 217 gallons daily or 45 per cent greater. The difference is largely due to the greater use of water for lawns and gardens in the average California city. Average, minimum and maximum lines have been drawn on the diagram with the following results:

Line	Rate of depth increase per annum for each 10 persons Feet	Daily per capita consumption Gallons
Average	1.19	106
Minimum	0.56	50
Maximum	2.44	217

Rates for water for industrial use have the same influence upon water consumption as in American cities generally. The effect of meters in reducing loss and waste is also apparent. In addition to having a greater rate of water consumption, California cities differ from the average American city in having a relatively small industrial demand. The use of water for irrigation of lawns and gardens appears to be great enough to more than offset the deficiency in industrial demand. This fact points to a material increase in future demand in California cities which may be fortunate enough to have rates low enough to attract industry.

A tabulated summary of all data compiled for American and California cities has been prepared herewith as Tables 2 and 3. These tables set forth the depth of water used in general municipal service in feet per annum for minimum, average and maximum consumption, and for densities of population from 5 to 50 per acre. Their field of application is in estimating future water consumption in self-contained community units. The data does not apply, however, to special services and segregated areas, such as strictly residential, industrial or agricultural. For such, the results of special tests are necessary.

Waterworks reports are usually lacking in information regarding the use of water for special purposes, such as domestic, commercial or industrial. The rate of per capita consumption, as determined from statistics in such reports, is a composite made up of all varieties of use, and throws but little light upon any one type. The only available source for such data are reports of special tests. With the increased tendency toward zoning, as stimulated both by city and regional planning programs, more detailed information is coming to be in greater demand. The following specific data for consumption in California cities has been obtained from various sources, and will be presented (in a forthcoming issue.—Ed.) in the hope that it will stimulate the more systematic collection and publication of such information. In addition to other uses, such data would be very valuable in distribution system design.

TABLE 2—AVERAGE WATER CONSUMPTION FOR TYPICAL AMERICAN CITIES 80% OR MORE METERED EXPRESSED AS DEPTH OF WATER OVER SERVICE AREA

Density of Population	Depth of water over service area—feet per annum: Minimum Consumption 50 gals per capita	Average Consumption 95 gals. per capita	Maximum Consumption 150 gals. per capita
5	0.28	0.54	0.84
10	0.56	1.07	1.68
15	0.85	1.60	2.53
20	1.12	2.15	3.37
25	1.40	2.67	4.22
30	1.68	3.20	5.05
35	1.97	3.73	5.90
40	2.25	4.26	6.75
45	2.53	4.80	7.59
50	2.81	5.34	8.44

Data based upon curves drawn for 95 typical cities (Diagram 1).

TABLE 3—AVERAGE WATER CONSUMPTION FOR TYPICAL CALIFORNIA CITIES 80% OR MORE METERED, EXPRESSED AS DEPTH OF WATER OVER SERVICE AREA

Density of Population	Depth of water over service area—feet per annum: Minimum Consumption 50 gals. per capita	Average Consumption 106 gals. per capita	Maximum Consumption 217 gals. per capita
5	0.28	0.58	1.18
10	0.56	1.16	2.37
15	0.84	1.78	3.55

Water Seers

NOWHERE is the problem of estimating future needs so important or so difficult of solution as in the field of irrigation and its allied field, waterworks. The problem of determining the amount of water which will be required for the years to come presents itself whenever a new irrigation project is undertaken or a step taken to provide additional domestic water supply.

A summary of the recent trend of thought in these fields is surprising in its revelation of the extent to which men are looking to the future. The mushroom growth of the West has taught its lesson to those who are responsible for the management of waterworks and reclamation projects. "Tomorrow" comes sooner in the West than it does anywhere else.

Then too, from the standpoint of costs, as one hydraulic engineer has recently pointed out, it is often desirable to design and build major structures for the ultimate supply in order to meet the requirements of economy. Expenditures for water rights and lands become necessary long in advance of actual need. It is quite common, in fact, for large cities to look ahead 40 to 50 years in their municipal water construction problems, and where located in regions of limited supply the acquisition of lands and water rights from 75 to 100 years in advance is not unusual.

RECENTLY there have been several manifestations of this growing tendency to look to the future. In the field of reclamation and irrigation Herbert Hoover is probably the foremost exponent of the theory that new irrigation works must be built before the actual need is felt. The keynote of the Secretary's recent western trip was the urgency of looking to future needs in developing the nation's water resources, a stand on which he has been opposed by many who are unable to visualize the future or who lay the troubles that befall the farmer to overproduction more than to distribution and marketing.

Waterworks men, too, are giving voice to the need for looking to the future. Those who attended the recent convention of the California Section of the American Water Works Association at San Diego must have been impressed with the theme of the three speakers who came to tell of the work of the three metropolitan areas of San Francisco, Los Angeles, and San Diego. Incidentally, their papers told of what *had been* done, but primarily they told what *is being* done and what *will be* done in anticipation of future needs. There were no post-mortems over the past, but rather intelligent discussions of anticipating the needs of people not yet born.

This is a happy sign. Stories of individual successes generally attribute these successes, among other things, to vision. The man who is thoughtful enough to prepare for tomorrow, for the job ahead, is the one as a rule who attains success. Likewise, the success of nations depends in considerable measure on this attribute; and the way these western United States, the baby states of the Union, are envisioning the years to come in their water developments is reasurring evidence that the future of the nation will be well taken care as far as that all-essential requisite of life—water—is concerned.

Oregon Goes Ahead

OREGON is going about the solution of its reclamation problems in a business-like manner judging from the accomplishments of the sixteenth annual session of the Oregon Reclamation Congress. The state is developing a state-wide organization for orderly reclamation and the relief of settlers on sick projects.

It is interesting to note the principals enunciated by the Congress in reply to its legislative committee for constructive suggestions. It was declared:

1. That the State be not called upon to assume the liabilities of irrigation districts.

2. That the control of all reclamation matters be vested in the State Irrigation and Drainage Securities Commission.

3. That provision be made to prevent pyramiding of taxes so that settlers will be protected and the obligations of each limited to a definite fixed sum.

4. That legislative machinery be provided to permit and encourage the pooling of all interests involved on any project wherein default has occurred, to the end that constructive cooperation may be secured.

"Western Waterworks" Begins on Page 25

POINT *Of* VIEW

5. That such amendments be made to the present irrigation district law in the matter of payment of operation and maintenance charges so that the district's officers may have the option of collecting such charges in advance instead of through the county officers, as now provided, and that they have the further option of denying water to the settlers until such charges are paid, provided that such action will not release the land from the lien of operation and maintenance charges once levied.

6. That on any new irrigation district projects which may be undertaken, and on existing projects, as far as possible, assessments should be made in proportion to the benefits to be derived from the water right supplied.

7. That operation and maintenance charges be based upon a fixed charge for the first unit of water supply and an additional charge based on additional quantity of water delivered.

8. That the foreclosure of delinquent tax certificates follow the form or practice now followed by the County Courts in the foreclosure of delinquent general taxes, to the end that the procedure may be simplified and the cost to the irrigation district lessened.

9. That an immigration department be created for the purpose of assisting in the colonization of all projects.

The irrigationist interested in management problems will find in these nine points a broad legislative program that, while it contains several good ideas for the benefit of reclamation, will probably require a long time to complete, if one bears in mind the speed of legislative machinery. What Oregon is trying to do is to follow up its campaign of getting colonists to come to the state by providing a management of its projects that will keep people on these projects after they come. Progress is being made and reclamationists in the state are to be congratulated on the spirit of cooperation and mutual understanding manifested in their recent meetings.

Championing the Settler

MODERN IRRIGATION recently published in these columns its comment on the government's action in charging off $27,000,000 as a definite loss on reclamation projects that have failed ostensibly because of poor soil conditions. The question was asked, "Is It Worth It?"

C. S. Heidel, Montana State Engineer, writes to the editor his belief that a more complete analysis of the situation would show up the settler in a better light than this journal has pictured him.

"There is," explains Mr. Heidel, "a condition that we sometimes fail to consider; namely, that some of the settlers on Federal projects have lost their savings and ruined their lines in attempting the impossible task of working farms which, because of soil conditions or other reasons, can not now be farmed successfully.

This condition, our critic points out, was referred to in Dr. J. A. Widtsoe's paper printed in Modern Irrigation for March. "It is," he continues, "manifestly unjust to farmers who are now settling on or have managed to stay on productive portions of projects to saddle them with an overhead charge to pay for works constructed on other land which can not be profitably farmed. If the Secretary of the Interior and the Commissioner of Reclamation are permitted to delay construction of future projects until economic considerations warrant their development there will be little probability of later need for the cancellation of construction charges on such projects."

"In discussing the cancelled and suspended payments," concludes this writer, "we should not forget the ruined settlers who have lost their fortunes in attempting the impossible. I feel that a full consideration of irrigation history leads to a conviction that present settlers should not be forced to bear an undue proportion of the expenses caused by early errors or mistakes on the part of others."

Our Montana reader's point is well-taken, without doubt. Much of the loss on reclamation projects must be charged to poor soil rather than poor farming. A complete confidence in their government's wisdom and judgment has caused many farmers to settle on lands that never will produce profitably and in these instances surely the settler cannot be held responsible for the loss which the taxpayer must shoulder.

As Dr. Widsoe points out, in the article referred to above, colonization wisdom demands that the projects to which prospective settlers are invited are inherently capable of successful development. But—the prospective must be selected according to his fitness to live and labor under prevailing project conditions. It takes a man of distinct gifts to become a successful farmer. This fact must not be overlooked by those who champion the settler's cause.

"Danger" from Reclamation

SECRETARY of the Interior Work says that he is not disturbed by charges from agricultural States that we are at present over-producing in agriculture beyond the demand for our products, with correspondingly lowered unprofitable prices to the producer in this connection.

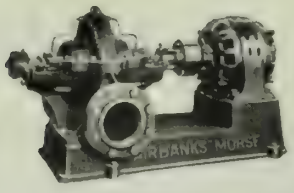
He declares that "we have been developing Federal reclamation in the West for 25 years and what we have produced is negligible when compared with the production of the whole country. The 1,242,750 acres on Government irrigation projects, last year produced crop values of $96,100,000. When these totals are compared with 372,000,000 acres farmed in the entire United States worth $13,031,000,000, we may safely ignore the immediate danger from reclamation."

He adds, "we should look to the future—25, 50 or more years distant—rather than now, as the bringing in of new land is a slow process at best."

It is a well recognized fact that the direction of the first step is more important than the length of it.

If there is any danger from reclamation it is in our failure to make complete use of water resources. Yet, as another authority has said, "we must have for each decade a practical economic duty of water according to our time and conditions. The broad principle of beneficial use will allow adjustments from one decade to another that will permit taking up and utilizing waste."

"Western Waterworks" Begins on Page 25



How much attention should pumping equipment require?

Take the Fairbanks-Morse pumping unit illustrated above. This motor pump outfit requires about the minimum attendance imaginable. Lubrication, for example, is a simple matter of greasing the bearings at six month intervals. Practically no other attention is needed. Every bearing is a ball bearing, which means that friction and wear are practically eliminated. The shaft is carried on permanently true centers and the proper running clearance is maintained between impeller and wearing rings.

This unit is typical of other Fairbanks-Morse pumping equipment that is setting new standards of dependable, economical operation and long life in irrigation service. One advantage of using Fairbanks-Morse equipment that has appealed to many irrigators, is the fact that a complete Fairbanks-Morse installation can often be used—all pumping and power equipment furnished by one manufacturer with no split in the responsibility for satisfactory service.

Whatever your requirements, investigate Fairbanks-Morse equipment for filling them. The advice of our engineers is always available. Write the nearest branch for bulletins and other literature.

Atkinson and Spicer Lowest Bidders on Coolidge Dam

Construction Is of New Multiple Dome Type; Los Angeles Firm Submits Figure of $2,268,525.50

Bids have been received by the United States Indian Irrigation Service to build the Coolidge Dam near San Carlos, Arizona. Low bid to erect the structure was submitted by the Atkinson & Spicer Company, of Los Angeles, at $2,268,-525.50. Nine bids were submitted.

The site for the Coolidge Dam is located at the entrance to Box Canyon on the Gila River, nine miles south of San Carlos. It will impound approximately 1,200,000 acre feet of water to be used to irrigate about 100,000 acres of land. The land to be irrigated lies in the vicinity of Florence and Casa Grande and is owned partly by the Pima Indians on the Gila River Indian Reservation.

Dimensions of Dam

Rising 250 feet in height the dam will have a width of 300 feet at the base and 600 feet at the crest, and will be 110 feet thick at the base. Constructing the dam will necessitate the removal of approximately 209,000 cubic yards of material and the structure will involve 190,-930 cubic yards of reinforced concrete which will require the use of 223,300 barrels of cement and 2250 tons of reinforcing steel.

Contract to build the dam, which will be a new type known as the multiple dome dam, will be awarded within thirty days and the contract to execute the work provides for completion of the dam before June 1, 1929.

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC., REQUIRED BY THE ACT OF CONGRESS OF AUGUST 24, 1912.

Of Modern Irrigation published monthly at Los Angeles, California, for October 1st, 1926.

County of Los Angeles } ss.
State of California, }

Before me, a Notary Public in and for the State and county aforesaid, personally appeared Walter C. Monroe, who, having been duly sworn according to law, deposes and says that he is the Business Manager of the Modern Irrigation, and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management (and if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 411, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers are:

Publisher—Petroleum World Publishing Company, Los Angeles, California.

Editor—Russell R. Palmer, Los Angeles, California.

Business Manager—Walter C. Monroe, Los Angeles, California.

2. That the owner is: (If owned by a corporation, its name and address must be stated and also immediately thereunder the names and addresses of stockholders owning or holding one per cent or more of total amount of stock. If not owned by a corporation, the names and addresses of the individual owners must be given. If owned by a firm, company, or other unincorporated concern, its name and address, as well as those of each individual member, must be given.)

Owen Brown, President, 626 S. Spring St., Los Angeles, Calif.

The Water in Your Ditches Will Flow in Steady Even Stream

if you build and clean your ditches with the MARTIN DITCHER. It will do the work fast and at a low cost and you will have smooth bottoms, even banks — a ditch cleared of grasses, weeds, sand, muck or anything that might hinder the flow of the water. You cannot do without one. It will pay for itself many times over.

Holtville Installs Jetties

Holtville division of the Imperial Irrigation District, California, received 18,618.11 second feet of water during the month of October, according to the report received at the district offices. Deliveries in the division for the month totaled 11,376.16 second feet, an increase of 6,530 second feet over the same period in 1925 and approximately the same amount delivered in September, 1926. The payrolls total for the month is shown as $11,710.46, with 110 employes. The installation of a number of Kellner jetties at points in the Alamo river channel occupied the attention of crews during the month. These jetties are said to be proving effective in opening up new channels capable of carrying off the full flow of the river.

Mexico Plans First Project

Plans for the first project in connection with the irrigation program of the Mexican Government have been completed, according to information recently received at the U. S. Department of Commerce from George Wythe, acting commercial attache at Mexico City. It is said that the first project to be carried out will be undertaken near the head waters of the Lerma River in the northeast corner of the state of Michoacan, Mexico. Plans are being prepared, it is reported, for a great masonry dam to be built across the Rio Lerma at Tepuxtepec, in the municipality of Contepec, behind which will be stored 500,000,000 cubic meters of water for use in a great irrigation and hydro-electric power development.

Today's Edition of a Book for 10 Years a Standard

USE OF WATER IN IRRIGATION: BY SAMUEL FORTIER; THIRD EDITION, $3.00

Introducing the first edition, (1916) the author wrote: "The volume aims to benefit three classes of readers: new settlers, irrigation farmers, and students in agricultural and engineering classes. The subject matter is confined almost exclusively to the irrigated farm and to the problems which confront the irrigator. In this respect it is an Irrigator's Handbook." In the preface to the third edition, (1926) Dr. Fortier writes: "During the decade . . . the practice of irrigation has been much improved, the farmers' part in irrigation better understood and appreciated, and fundamental principles more fully elucidated. It has been necessary to add a number of new articles, and to rewrite and enlarge much of what appeared in the earlier editions."

420 pages of wisdom and common sense applied to Irrigation

THE HYDRAULIC DIGEST

A Monthly Bulletin Board of Brief Facts and Events from Far and Near

El Camino Votes Bonds

El Camino Irrigation District, California, recently voted $420,000 bonds for completing the laying of underground pipes for the irrigation of 7,500 acres. Fred H. Tibbetts, of San Francisco, is the engineer in charge.

La Salle Wants Canal Bids

La Salle County, Texas, Improvement District No. 1, through W. A. Kerr, secretary of the board of directors, has asked for bids on 100 miles of main canals, 175 miles of laterals, and approximately 2 miles earthen reservoir dam across the Nueces River.

Flood Control Bonds Defeated

The proposed $26,000,000 bond issue for more extended development of the Los Angeles County Flood Control District was defeated at the election of November 2. This proposed issue was to supplement the work begun two years ago, when an issue of $35,300,000 was passed.

LaConner May Buy System

The city council of LaConner, Washington, is considering the question of purchasing the local water system. The present owners are desirous of selling and are unwilling to invest any more money in the plant for needed improvement. Under existing conditions, the council reports, the best outlook for development of the system is in municipal ownership.

San Carlos Would Buy System

The San Carlos, California, Chamber of Commerce, recently passed a resolution urging the purchase of the plant and properties of the San Carlos Water Company. The proposal recommends that San Carlos take over the entire system of the company and that additional wells be installed in order that the community may have sufficient water supply for its increasing population.

Turlock Will Vote on Bonds

The Turlock Irrigation District, California, through its board of directors, has fixed December 1 as the date for submitting a bond proposition of $514,000 to the taxpayers for a vote. The funds derived from this issue, it is planned, will be used for installing two additional units at the Don Pedro Dam power plant.

Raise Water Rates 50 Cents

The Grass Valley, California, city council recently voted to increase water rates for the city by the addition of 50 cents to each $1.28 monthly charge, and to devote this sum to needed replacements, betterments and extensions of the system. The distribution system is owned by the city, water being bought at wholesale from a power company.

Ojai Plans Flood Control

A proposal that a county-wide survey be made of the water resources in Ventura County, California, with a view to the conservation of these resources and their just apportionment throughout the county has been made by those interested in forming a water conservation district at Ojai. The Ojai conservationists propose to form a district in Horn canyon and construct a series of check dams to hold the water through underground storage. The district would comprise the lower valley and the upper valley as far as the Santa Ana.

Two States Reject Water Bills

Oregon and California voters defeated proposed constitutional amendments for state development of water and power resources. The California bill proposed a state bond issue of $500,000,000 for state-owned and operated water and power developments. The Oregon bill proposed creation of a board of five elective members with full authority for the conservation, development, storage and distribution of electric energy and water for domestic and irrigation uses, and a bond issue not to exceed 5 per cent of the state valuation.

Filter System in Good Order

Post-season inspection of the Sacramento filtration plant, just completed by Alan J. Wagner, city engineer, shows the plant to be in good condition. Only a few minor cracks were found in the sedimentation basin, which was completely drained for the inspection. Although the plant was designed for a maximum daily output of 32,000,000 gallons, on several occasions during the summer 45,000,000 are said to have been used. Construction on the additional filtration beds may be delayed until spring because of the questioned validity of the bonds voted for the work.

Votes $3,065,000 for Water

The Roosevelt Irrigation District, Arizona, voted almost solidly for a bond issue of $3,065,000 on October 26. This new district comprises some 40,000 acres of land, much of which is classified as suitable for citrus fruits, and is served by the Southern Pacific railroad and the state highway to Yuma. It lies west of the Agua Fria river and extends from above the Buckeye district to the Hassayampa river. It is planned to irrigate

Condemns Cambria's Water

The San Luis Obispo county health department has given the citizens of Cambria until December 15 to secure a different water supply from that used at present, according to a recent report. This decision was made upon the advice of H. H. McCormick, sanitary inspector, who states the water is unfit for consumption because of the seepage of sewage. The present water supply is obtained from a system of wells, and the trouble has arisen, it is claimed, because the wells are not deep enough and the pipes are eaten with rust.

Railroads Tap Arizona Projects

Arizona irrigation projects are assured of the co-operation of the railroads in the development of the lands reclaimed from the desert. The Southern Pacific recently celebrated the opening of its new $15,000,000 line through Phoenix and the Salt River Valley; and the Santa Fe Coast Lines, through W. K. Etter, general manager, have announced the proposed construction of a branch line, fifteen miles in length, that will tap the news Beardsley irrigation project, comprising 40,000 acres in the Salt River Valley, 20 miles west of Phoenix. Grading for this line is expected to start by January 1, 1927.

To Every Business or Professional Man!

WESTERN Waterworks
Supplement to Modern Irrigation
Of Interest Expressly to Waterworks Executives, Contractors, and Municipal Engineers

California Section's 7th Annual Convention Draws Big Crowd; Morris New Chairman

ALL records for attendance were broken at the seventh annual convention of the California Section of the American Water Works Association, held at San Diego, October 27, 28 and 29. From the standpoint of the interest manifested in the program and the exhibits, the meeting was also the most successful of any held since the inception of the Section some seven years ago.

Not only were members of the waterworks fraternity present from California, but there were registrants from several other Pacific Coast states and British Columbia as well. The complete roll call of the convention will be found on another page in this issue of WESTERN WATERWORKS.

It would be difficult to chronicle the complete proceedings of the convention in one issue of this publication, but an attempt has been made to cover, to some extent, all of the important phases of the three-day program. Many of the papers read before the meeting are reproduced on the following pages of WESTERN WATERWORKS, and others are scheduled for early publication. Special arrangement with the Journal of the American Water Works Association makes it possible for WESTERN WATERWORKS to publish these papers prior to their publication in the Journal.

Any story about the convention would be incomplete without mention of the exhibits of the manufacturers of waterworks equipment, an annual feature which always draws the interest of waterworks men, both at the California Section conventions and the national gatherings of the parent organization. When the convention was formally opened Thursday morning, the convention hall in Balboa Park, with its pleasing decorations and excellent exhibits was ready for inspection. Without doubt, the major share of the credit for the large number of exhibitors and the general excellence of the exhibits themselves goes to J. R. Barker, Pacific Coast manager of the Neptune Meter Company, who was chairman of the exhibits committee. Mr. Barker gave liberally of his time in interesting large numbers of manufacturers in displaying their products at the convention. In this work he was, however, very ably assisted by the other members of his committee.

Mueller's "triple threat."—Left to right: "Bill" Jett, Ward L. DeWitt and Thos. F. Leary of the Pacific Coast forces of the Mueller Company. Mr. Leary is Pacific Coast manager.

Credit for the lack of confusion attending the convention was due, in large measure, to A. P. Lovell, su-

(Cont. on P. 65)

Here and There
At San Diego

Professor W. F. Langlier, of the University of California, was among those present at the big show.

Bill Jett, the well-known representative of the Mueller Company of Los Angeles, was very much in evidence around the convention hall.

One wondered if the cast iron pipe men were endeavoring to make a good impression upon San Diego's city "dads." At least there was evidence of competition.

F. C. Finkle, consulting hydraulic engineer of Los Angeles, was seen taking in the show. Mr. Finkle, it will be remembered, was for many years chief hydraulic engineer for the Southern California Edison Company.

Among the many prominent and well known supply men seen was W. C. Mills, Pacific Coast sales manager for the General Chemical Company. Mr. Mills evidenced a keen interest in all of the convention's activities.

Arthur Crooke, of the Worthington Meter Company, Los Angeles, seemed to have his hands full piloting the extemporaneous orator of the evening. The Worthington Meter exhibit certainly created plenty of interest.

L. A. Safford and C. H. Johnson, of the De Laval Steam Turbine Company, were right there in explaining the efficiency of their pumps and telling of the arrangements they have at Los Angeles and San Francisco for quick servicing.

Another well known representative of the deep well turbine contingency was Joseph H. Cox, president of the Western Irrigation Equipment Association, and vice president in charge of sales for the Frank J. Kimball Company.

One of the outstanding booths at the convention was that of the James Jones Company with its striking background and interesting display of brass goods. W. W. Conner, known by waterworks men all over California, was in charge of the exhibit. Walter Jones also was seen about the convention hall.

Andrew Erwast, chief engineer of the Spreckles Company, San Diego, and Virgilio Bruschi, of the San Diego city council, do a little chinning.

R. W. Keene, W. L. King and Allen Jack, of the Hersey Manufacturing Company, must have a host of friends among the waterworks fraernity, judging by the company they were seen in at both the convention hall and the hotel.

O. C. Brand, representing A. D. Cook, Inc., of Lawrenceburg, Ind., evidently arranged for local representation in several parts of California for Cook deep well pumps, valves and hydrants as he was seen in deep conversation several times with different supply men.

R. F. Goudey, resident engineer, State Board of Health, Los Angeles, was with the bunch at San Diego. Mr. Goudey has been making some very interesting studies relative to the chlorination of irrigation water for the prevention of the transference of typhoid bacilli by green vegetables.

F. J. Henkenius of San Francisco, and G. J. Reardon of Los Angeles, represented the Kennedy Valve Company at the convention. These two were very active among the waterworks men, and made a host of friends.

The "Orpheus Four"—no, not Morpheus!—headed by H. M. Dudley, of the McWane Cast Iron Pipe Company, were certainly "there" with royal entertainment for the guests at the dinner dance on Friday evening. Mr. Dudley's voice is well known to a host of radio fans in Southern California and elsewhere in Radioland.

R. E. Brownell, general manager of the Palos Verdes Water Co., of the Palos Verdes Estates, did not let his in-

terest in water matters interfere with some opportunities to tell about the wonderful home-site project his company is developing near Los Angeles.

"Alex" Bell and his well known pipe were very much in evidence around the Wallace & Tiernan booth. There was always a crowd gathered about him, inspecting the working model that he was demonstrating, in cooperation with G. T. Luippold and A. L. Frick.

Since this was a waterworks meeting it is not strange that there were a number of Brooks in attendance. Frank Brooks of the Art Concrete Works was there assisted by his brother H. L. They had an interesting exhibit and took especial pleasure in showing their new number 65 box for large meters.

Geo. H. Bailey, Pacific Coast manager of the National Meter Company, was seen in animated conversation with several of the "big unit" buyers of water meters, so, in all probability, western sales records are due for another strong "upward turn," as they say on the stock exchange.

L. H. Chamberlain, Water Works Supply Company, says the speed cops around San Juan Capistrano are altogether too vigilant. The Water Works Supply Company was well represented at the convention. Among those present from this organization were C. B. Abbott, president; L. H. Chamberlain, Foster Manock, and E. A. Rutledge.

Among the well known figures at the convention this year, as in previous years, was Thomas Leary, Pacific Coast manlarge number of interested visitors.

ager for the Mueller Company, of Decatur, Illinois. "Billy" Jett, southern district manager, was another member of the Mueller staff who was much in evidence at Convention Hall and the various other get-togethers of convention week.

H. L. Dickinson, Pacific Coast man-

"I'm Only a Little Farmer Boy," the title of the oration delivered by James B. Howard, Earlimart, California, seemed to find either favor or flavor with all those who were included among the audiences.

ager, Chapman Valve Company, was taken ill while attending the convention, and had to leave early. O. J. Magary, represented the company, however, and was seen throughout the session. He thinks the convention was the best to date, as more interest was shown, both in the manufacturers' exhibits, and in the papers that were presented.

J. E. Lundy, general manager of the Sterling Pump Works of Stockton, California, and B. A. Tucker, sales manager of the Pacific Pump Works of Los Angeles, were among the pump men in attendance at the convention. Both are familiar figures at the bi-monthly meetings of the Western Irrigation Equipment Association and at all other gatherings of the irrigation and waterworks fraternity.

It is a long time since Eve handed Adam the apple, but C. B. Meskimons, of the Philbrook Spring Pipe Clamp Co., knows they still make a darn good "lure." He had a box of fine Oregon apples in his booth. If you were down at San Diego and did not get one—or more—it must have been your own fault. And, incidentally you lost an opportunity to examine a mighty good pipe clamp.

The Western Pipe & Steel Company went to a great deal of work to prepare their booth in the convention hall. Seven or eight men were employed nearly a whole afternoon in bringing in the large section of fabricated steel pipe that formed the "outer boundary" of the booth, so to speak. This company had a very attractive exhibit and their efforts were well rewarded, judging from the

Black Canyon Dam Site on the Colorado River, Looking Upstream.

Colorado Aqueduct Will Cost Los Angeles Less Per Capita Than the Owens Project

Outlay for Proposed Pipe Line Would Be from 150 to 200 Millions; Blythe Route the Best

By WILLIAM MULHOLLAND

Bureau of Waterworks and Supply, Los Angeles

THE City of Los Angeles is on the edge of a desert. You may go in any direction from the City of Los Angeles, north, south, east or west, and you will find the desert before you go very far,—the arid, grinning desert.

The City of Los Angeles had to go 250 miles to the north over three mountain ranges and across deserts and waste plains to the Owens River to get her last water supply.

Discusses Pumping Costs

We pump water in the City of Los Angeles. The criticism offered the proposed aqueduct from the Colorado River to Los Angeles is that we won't be able to pay the cost of pumping this water by the time we get it to Los Angeles. We know what it costs to pump water; our pumped water today is 80 million gallons a day. That is more than San Francisco and Oakland use, yet we pump that much. You cannot scare us with pumping water if we can get water with no very great taxation but that of pumping.

In addition to that the Colorado River carries with it the proposition of power development. There is tremendous power to be developed, and I will say that we propose to build a power plant. Fifteen hundred second feet will require just about a third of the power that will be developed in the building of the Boulder Canyon Dam. You cannot put power to better use as far as Los Angeles is concerned or as far as California anywhere is concerned, than to pumping water to be put to profitable use.

We can pump the water there if we get the power at cost plus the cost of operation, for five cents per hundred, for we are selling water today for 13 cents a hundred feet so there is a good margin before we reach the limit of twenty cents a hundred feet. They charge 25 or 28 cents in Oakland or San Francisco and I claim right now that that is cheap water. Why should a man get water, water the essential element of life, cheaper than it costs him to polish his shoes or pay for his telephone? The telephone rates in Los Angeles are far in excess of the rates for water. They should not be. We can stand to pay far more than we do for the water.

I am not protesting against the rates of the City of San Francisco or Oakland. I have always found that the rates are perfectly justified. The people who brought water there and entered into the enterprise of supplying those two great cities with water were justified in making the rates they did, rates which were made anyway by the railroad commission. If we can get water into the City of Los

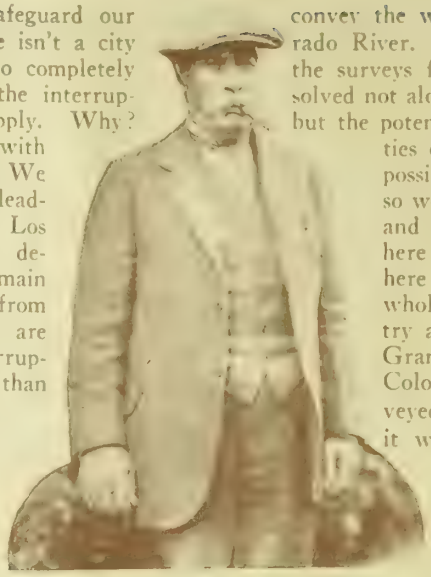
Mr. Mulholland's Model of the Proposed Boulder Canyon Dam to be Located at the Spot Pictured Above.

Angeles for twenty cents a hundred feet and I am certain we can, from the Colorado River by the building of the aqueduct that we now propose, we still will have cheaper water than the average large city in the United States.

Remember, other large cities that front on rivers or lakes have never had to worry about the water supply. The City of New York had the greatest problem and yet she never went more than 120 miles; and there were no mountains to climb; it all came by gravity. She is the only city that had any great water problem; the others just dipped their suction pipes into the rivers or lakes. You gentlemen have to contemplate in your everyday business, greater problems than any city in the East; you have a more expensive job before you.

Now the City of Los Angeles is peculiarly situated; a great area to the north of it, the San Fernando Valley, is very rapidly filling up. It was used as the dumping ground when the Owens River aqueduct was brought in; we didn't know what to do with the water pending its need for domestic use, and it was used there temporarily until we should know what to do with it. Population is increasing in the San Fernando Valley by leaps and bounds until it will be no time at all until that valley is densely settled. So we have built reservoirs on the margin of the Santa Monica mountains where we now have stored, free from any risk of interruption, these reserves. These reservoirs are very capacious; they have an average capacity of 30,000 acre feet and the mains run right into the city.

The City of Los Angeles has a waterworks that has a tremendous mileage of pipe; the people from the insurance companies used to come and wonder how we were going to safeguard our water supply. There isn't a city in America that is so completely safeguarded against the interruption of its water supply. Why? Because it was built with that end in view. We have thirteen mains leading into the City of Los Angeles; we do not depend on any one main carrying the water from a remote place; we are less exposed to interruption of water service than any city in America.



"I am not taking any particular credit for the Los Angeles water system. I have to thank my organization for that. I think, though, that it was the Koran or some other high religious authority that said: "He who bloweth not his own bassoon the same shall not be blown."

Praise Staff

I am not taking particular credit; I have to thank my organization for that. The thing seemed to be suggested naturally and it was so built. I think it is the Bible or the Koran or other high religious authority that said: "He who bloweth not his own bassoon the same shall not be blown."

This map, which I now present for your attention, is presumed to represent the new project of the City of Los Angeles. It embraces the territory lying between the Colorado River and the Pacific Ocean and southerly of the Boulder Canyon dam site. I point out here the Colorado River on its western boundary. As shown on this map, to the north and where the great bend on the Colorado River is situated is the Boulder Canyon Dam.

I have outlined here the ostensible first route surveyed for the aqueduct to convey the water from the Colorado River. Since we started on the surveys for this route we resolved not alone to survey that line but the potentialities and possibilities of other directions to possibly get a cheaper line, so we started broadcasting and within the boundary here shown clear up to here and taking in the whole Boulder Dam country and clear over to the Grand Canyon of the Colorado, we closely surveyed every bit of it and it will be shown in our complete topographical map.

Country Mapped

That whole country is worked out and a model relief map made of the whole area, so that we can go in front of that map and you can plot an existing route or any alternative route without leaving our office. Every bit of it has been traced mile by mile; we found out where tunnels have to go, where siphons have to go, where the ground is too high or too low. It is the most monumental piece of work ever constructed. It is now within a month of being completed.

I will say in regard to this route direct from Blythe to Los Angeles that it is the one that has the least tunneling; it is the one that comes out with the higher point of delivery. I will not deny the fact that I am in favor of that rõute; I don't like to boast about the discovery but if you turn a jackrabbit loose at the Colorado River there and scare him enough and headed him for Los Angeles he would go that route.

Curiously enough that route is almost to a mile the same length as the other big one we built, the Owens River aqueduct.

Now let's check up the cost of this thing. The Los Angeles aqueduct cost us a bond issue of $153.00 per capita; we had 160,000 people in the city at that time. Now that didn't scare the people; they went to the bat and they built the aqueduct and they got their benefit in the shape of billions of dollars in increased value to the real property alone, which paid for the aqueduct many times over.

That debt is a little over a third paid off, very nearly a half paid off now, and we are going to undertake another debt. The estimated cost in the rough is between 150 and 200 million dollars; it

(Continued on Page 33)

Here is the relief map referred to by Mr. Mulholland in the accompanying article. The San Bernardino mountains are in the foreground. The map covers approximately 35,000 square miles.

STORAGE & DISTRIBUTION

Corrosion Problems of a Water System and Methods of Protection

Determination of Corrosion Power of Certain Soils Is Big Job Confronting Waterworks Men

By E. B. STEWART

Electrolysis Engineer, East Bay Water Company, Oakland, California

Editor's Note: Mr. Stewart's paper—one of those read before the annual convention of the California Section of the American Water Works Association—will be published in two parts. Part I, in this issue, concerns soil corrosion. Part II, which discusses corrosion from externally applied electric currents, will appear in an early number.

THE subject of corrosion has not in the past been given the consideration the importance of the subject might warrant. The lack of interest is probably due to the fact that pipe systems are as a general rule looked upon as practically indestructible, and when once installed require no further attention or replacement. Experience has shown, however, that pipes are always subject to corrosion, and under certain conditions, serious damage occurs in a short period of time.

Many corrosion problems have simply been looked upon as unavoidable and repairs and replacements have been made without any effort to locate and remove the cause.

The subject of electrolysis will always be a pertinent subject as long as the running rails are used as a return path for the railway current. Improvement in rail bonding, the use of lager rails, and the more frequent distribution of substations, thereby reducing the distance that return current must travel on rails, have been of material aid in reducing this form of corrosion.

Theory of Corrosion

Before taking up methods of preventing corrosion, a brief explanation will be given of the manner in which corrosion takes place, for unless there is a fair conception of the fundamental factors influencing corrosion rates, it will be difficult to know what protective methods will be most suitable.

It has been conclusively shown that corrosion does not take place to any appreciable degree unless the metal be in contact with both water and free oxygen. The action is practically nil where the metal is in contact with oxygen alone, or oxygen free water alone. In other words, all three elements, namely, metal, water and free oxygen must be brought in contact to cause corrosion.

It has been shown that when iron is placed in water, a multitude of electric potentials are immediately established between the metal ions and the electrically charged ions in the water. These potentials cause metal ions to go into the solution and set hydrogen free. This hydrogen gathers on the surface of the iron in the form of a thin invisible film, and tends to retard the progress of corrosion by insulating the metal from the solution, and thus prevents further corrosion taking place. In order that corrosion may continue, the film of hydrogen must be removed. This may be accomplished by dissolved oxygen which is usually present in water combining with the hydrogen film to form water. The film having been removed, more iron can go into solution, more hydrogen can plate out and the process can continue at a rate determined by the speed with which the oxygen removes the hydrogen.

"Solution Pressure" Defined

The tendency of a metal to go into solution in a conducting liquid called the electrolyte is accompanied by an electrical potential between the metal and the solution. This potential is known as its "solution pressure" or "potential pressure" and is different for different metals in contact with the same solution and also different for different solutions in contact with the same metal.

Hence when two dissimilar metals are placed in a conducting liquid, a galvanic battery is formed and the difference in potential between the metals is proportional to the difference in their "potential pressures." When the metals are connected by wire, an electric current will flow through the wire between the metals, and the electropositive metal will corrode at a rate inversely proportional to the resistance of the circuit. Therefore, the rate of corrosion will be a maximum when the metals are brought in physical contact, which is usually the case in practice. In this case the circuit will be completed internally through the metals.

Corrosion resulting from contact of dissimilar metals is commonly called "galvanic action." This form of corrosion is often not generally understood, probably for the reason that it occurs under conditions that are difficult to study.

Corrosion in Practice

An example illustrating the effect of corrosion from this cause in practice is found in the destruction of our service pipes at the union connecting the lead goose neck. Many cases have been found where the service pipe shows general corrosion immediately adjacent to the union. The service pipe is the electropositive metal, hence a galvanic current will flow from the pipe to the union resulting in corrosion of the latter.

An insulating bushing placed between the pipe and the union was found to be the most economical method of preventing this type of galvanic corrosion. The electrical circuit is thus broken and the corrosion hazard is eliminated. This insulating medium also prevents the flow of stray railway currents.

There are many cases where it is impracticable to insulate dissimilar metals

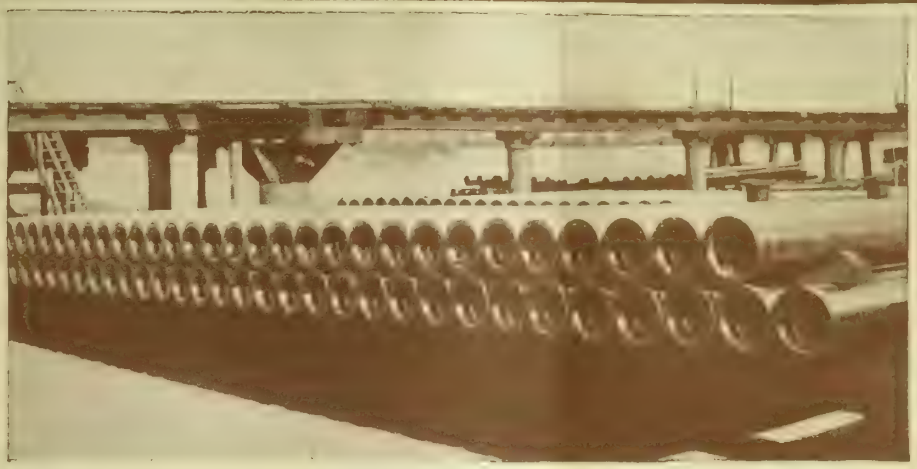
Preventive Measures

DAMAGE to pipes by soil corrosion may be prevented by two methods:

(1) Covering the pipe surfaces to insulate them from the earth.

(2) Making pipes negative to earth by external current or by the application of more anodic metals. This method is known as cathodic protection.

In the study of soils to determine the type of coating necessary to prevent soil corrosion, stray current from railway tracks should be taken into consideration. For instance, no coating is necessary on pipes located on railway lines where the potential of the pipes is negative to the rails regardless of the kind of soil, because it is well known that no corrosion takes place where pipes are negative to the earth. In some cases we have made small pipes negative to earth by connecting zinc plates to the pipe at intervals determined by earth current measurements. The plates are buried in the soil approximately one foot from the pipe. There is insufficient data available at present to determine the probable life of such protection, but from all indications, it appears to have some merit as a temporary expedient in localized cases.



deLavaud Centrifugal Cast Iron Pipe

—is now ready to ship in sizes from 4″ to 20″

The principal features of deLavaud Centrifugal Pipe are:

1—Lower cost per foot.
2—Greater carrying capacity due to larger inside diameter. Its smooth surface produces less friction.
3—An even greater resistance to corrosion owing to its finer granular structure.
4—Cheaper to install owing to its uniform lead space and self centering bell.
5—It is easier to cut and tap.
6—Its greater strength and uniform section makes it valuable for use for higher pressures.
7—Adaptability to special joints due to its smooth exterior and uniform circumference.
8—It is made to be used with standard fittings and specials.
9—Annealing gives a uniform metal with no casting strains.
10—This method of casting leaves no possibility for sand holes or gas pockets.

from physical contact with each other, particularly in well pumping equipment. In this case, it is desirable to select materials that are most uniform in texture. In some cases where cost is an important factor and the extent of the corrosion is limited, it may be advisable to select such combinations of metals as to make the least expensive metal electropositive and the most expensive metal electronegative.

Soil Corrosion

Natural soil corrosion is sometimes spoken of as "self corrosion" to distinguish it from corrosion due to externally applied electric currents.

On the whole, corrosion in soils is similar to corrosion in water, because the controlling factor in soil corrosion is water. For in the absence of water, no corrosion will take place. But since pure water does not corrode iron appreciably, it is obvious that the corrosive character of the soil depends primarily upon the presence of certain dissolved materials in the soil water, which originate both from the air and from the ground.

In other words the soil is an electrolyte of widely varying concentrations due to the many factors present such as soluble salts, acids, dissolved gases, etc., which makes a solution of high electrical conductivity and hence more stimulating to corrosion than pure water.

Factors Affecting Corrosion

There are certain physical properties of pipes which have more or less influence on the corrosion rate, such as, character and uniformity of the surface finish of the metal, segregation of impurities in the metal, composition of the metal, area of the metal exposed as anode, parts of the metal that have been scratched or bruised from rolling, hammering or threading. Some of these factors influence the total amount of corrosion. For instance imperfections in mill scale will cause pitting which is the most destructive form of corrosion. It is well known that mill scale is electronegative to iron, and hence galvanic action takes place between them when in contact with a conducting solution.

It is obvious that differences of potential exist between the points on the pipe surface that are in contact with soils of different concentration, since it is known that the "potential pressure" of a metal is different for different solutions. It follows, therefore, that galvanic currents will flow through the pipe between different points of concentration on the pipe surface, entering the pipe at points of low concentration and leaving the pipe at points where current leaves the pipe.

That corrosion does occur in accordance with these conditions, has been verified by the writer by placing non-polarized electrodes about six inches apart at right angles to a steel pipe, and noting the difference of potential between them when one electrode is very close to the pipe. Two points were located three feet apart where current was flowing away from the pipe at one point and entering the pipe at the other. An examination of the pipe indicated that corrosion was in progress at the point where current was leaving the pipe, while the pipe was found in good condition where current was entering.

When Lines Run Parallel

This brings out the fact that corrosion is stimulated when parallel mains are laid in close association with each other for the reason that the pipes act as conductors to complete a galvanic circuit between points of different concentrations in the soil. To illustrate the effect of corrosion under these conditions, a steel pipe laid eighteen inches distant from a parallel sixteen-inch main that was abandoned, showed with an earth current meter a relatively large galvanic current leaving the pipe toward the abandoned pipe at a point where serious corrosion was in progress. When the abandoned pipe was removed, this point became negative to the earth, thus preventing further corrosion. We have found from earth current measurements that pipes laid parallel in the soil should be at least four feet apart in order to prevent the flow of destructive galvanic currents.

One of the outstanding problems that confront waterworks people, together with all other utilities owning underground pipes, is the development of improved means whereby the corrosive power of certain soils may be determined. For if it were possible to determine the corrosive power of the soil, it would be possible to determine what form of protection, if any, would be most suitable for a particular kind of pipe at a minimum cost. The present knowledge of the corrosiveness of any particular soil is based largely on practical experience of the corrosion of pipes in similar soils.

Tests Started in 1922

In 1922 the American Committee on Electrolysis and the National Bureau of Standards in cooperation with a number of pipe manufacturers buried thousands of small samples of different kinds of pipe in about forty locations widely distributed throughout the entire country, with a view of obtaining a further knowledge of the effects of different kinds of soil on the corrosion of buried pipes. All kinds of soil and climatic conditions have been included in the tests. It is the plan to submit tentative reports as fairly definite results develop. The whole investigation is being carried out by the Bureau of Standards and is being

watched with great interest by the manufacturers and users of pipe.

Our investigations of the corrosiveness of soils indicate that very little corrosion occurs in soils having a resistance over 100 ohms per cubic centimeter.

Preventive Measures

Damage to pipes by soil corrosion may be prevented by two methods:

(1) Covering the pipe surfaces to insulate them from the earth.

(2) Making pipes negative to earth by external current or by the application of more anodic metals. This method is known as cathodic protection.

In the study of soils to determine the type of coating necessary to prevent soil corrosion, stray current from railway tracks should be taken into consideration. For instance, no coating is necessary on pipes located on railway lines where the potential of the pipes is negative to the rails regardless of the kind of soil, because it is well known that no corrosion takes place where pipes are negative to the earth. In some cases we have made small pipes negative to earth by connecting zinc plates to the pipe at intervals determined by earth current measurements. The plates are buried in the soil approximately one foot from the pipe. There is insufficient data available at present to determine the probable life of such protection, but from all indications, it appears to have some merit as a temporary expedient in localized cases.

(End of Part I)

Colorado Aqueduct Will Cost Los Angeles Less Than Owens

(Continued from Page 29)

won't cost as much per capita as the Owens River aqueduct. The city is proportionately richer than she was then, so it is no great undertaking.

I reasoned these things out—soothed myself; I am itchy about it; I am afraid to talk about that much money; I was brought up by frugal people in Ireland and there wasn't that much money in all Ireland I am sure. At any rate it will be about that sum and I don't think the people need fear to incur that debt, nor do I believe the people here will have any such fears. The people in Los Angeles are a canny kind of folks, but where they can see a profit they are going to invest; you can depend on that.

Drop in at our office any time and you will really see what that Colorado River desert country looks like in the minutest detail from our relief map, every rabbit hole, trail, road, and hollow, will be shown there. This detail is going to be tremendously advantageous in laying out the aqueduct.

IN THE WEST IT'S "WESTERN"

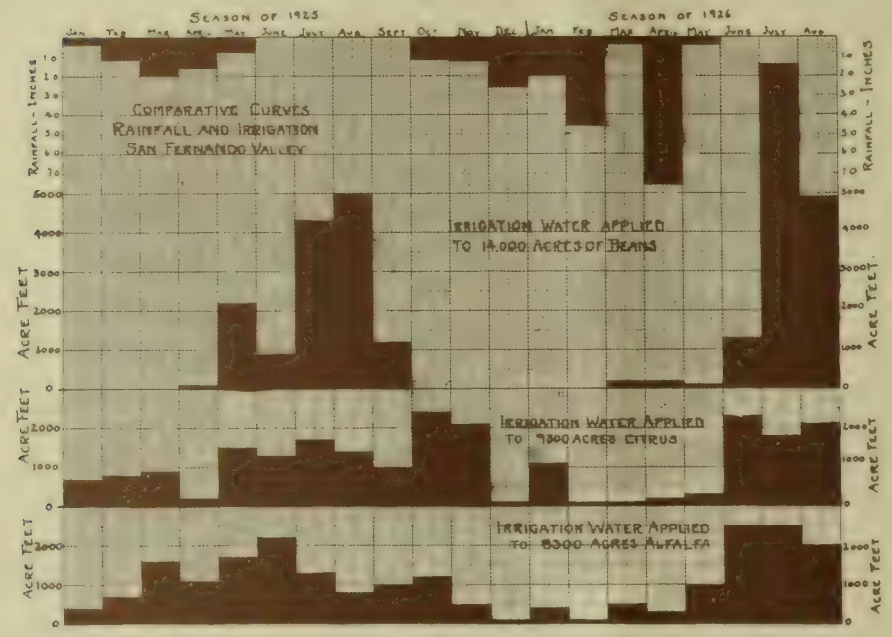
METERS & METERING

Read Issues Report for Los Angeles Meter and Service Department



Comparative curves, rainfall and irrigation water, San Fernando Valley

ACCORING to the annual report of George Read, superintendent, Meter and Service Department, Los Angeles Bureau of Water Works and Supply, the city water system had in service at the close of the fiscal year, June 30, 1926, a total of 218,635 meters as follows:

Meters in service, domestic and combination	211,231
Meters in service, intermittent irrigation	3,456
Jet meters in service, sewer flushing	3,948
Grand Total	218,635

The domestic and combination meters, according to size, were as follows:

⅝ in.	84,578
⅝x¾ in.	92,581
¾ in.	2,471
¾x1 in.	13,641
1 in.	10,003
1½ in.	4,509
2 in.	2,626
3 in.	474
4 in.	305
6 in.	43
8 in.	0

Total number domestic meters in service June 30, 1926	211,231
Number of meters in service July 1, 1925	197,476
Number of meters set during the year	13,755

Meter Failures

During the twelve months ending June 30, 1926, 22,534 meters were brought to the meter shop. Of this number, 14,823 were taken out because of failure to operate; 7,711 were taken out because of discontinuance or enlargement of the service on which they were set, or for minor repairs.

On an average for the year, 1235 meters were taken out monthly for failure to operate. The average percentage per month of the meters in service removed is .601, one meter for every 166 meters in service.

Table showing number of meters in service and percentages taken out monthly for failure to operate:

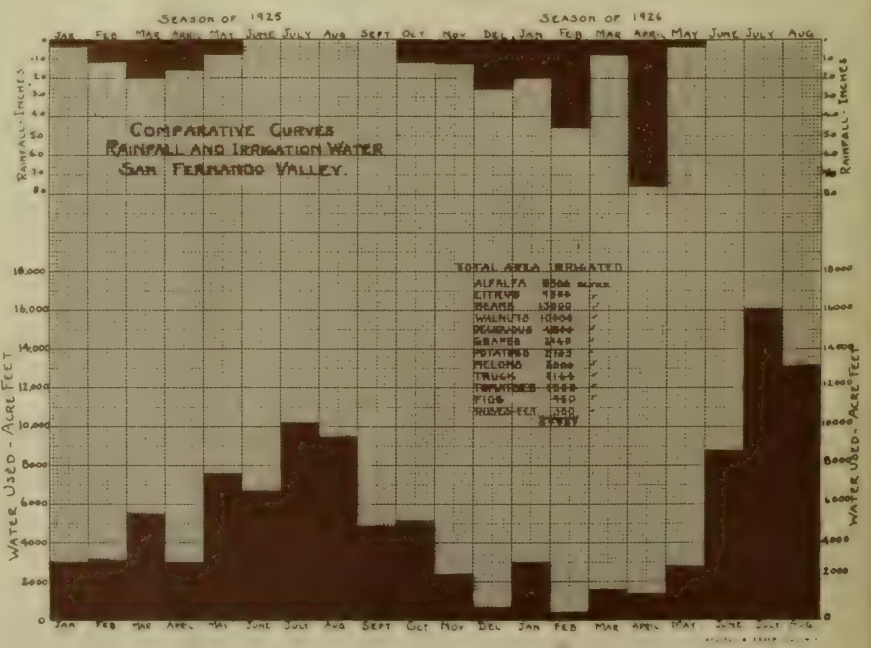
Meters in Service		Meters not Operating	% Taken Out
July, 1925	198,538	1,182	.6
Aug.	199,923	1,233	.62
Sept.	201,282	1,247	.62
Oct.	202,490	1,379	.68
Nov.	204,187	1,198	.59
Dec.	205,251	1,306	.64
Jan., 1926	206,308	1,077	.52
Feb.	207,220	1,254	.61
Mar.	208,446	1,335	.64
Apr.	209,536	1,150	.55
May	210,383	1,119	.53
June	211,231	1,343	.64

Average Upkeep 41 Cents

The average maintenance cost per meter, for all sizes in service, for the twelve months ending June 30, 1926, was 41 cents.

During the twelve months ending June 30, 1926, the department has changed 537 meters from straight to round reading meters. Most of these meters were taken over from privately owned water companies and are now being brought up to the standards of the department. Also, 6,761 meters were changed from open type gear trains to oil inclosed.

City officials of Burbank, California, are working on a comprehensive plan for the development of the local water system in connection with the expenditure of the bond issue of $150,000 recently voted.



Comparative curves, rainfall and irrigation water, San Fernando Valley

Beverly Hills Votes Water Bonds by Big Majority

Heavy Vote Polled; Will Spend Million Dollars for Improvement of Water System

The Beverly Hills, California, water bond issue, calling for one million dollars for the improvement of the local water system, was carried by a vote of 933 to 121 in a recent election.

Plans for a new filtration plant to cost $200,000, already practically designed, will be completed as the first expenditure to be made on the program of water improvement and the test work for the best type of coagulation for the filtration process will be proceeded with at once, according to Arthur Taylor, city consulting engineer.

The following is a summary of the various extensions and betterments for which the fund is proposed to be used and the estimated costs of same, as submitted by the city's firm of consulting engineers, Salisbury, Bradshaw and Taylor:

IMPROVEMENTS PROPOSED

Sherman Unit:	
Six new Sherman wells, pumping equipment, etc.	$ 44,000
Collection mains to Melrose and Sherman Ave., approximately 6000 feet, 8 to 16-inch	15,000
Pressure mains, Melrose and Sherman Ave., to Doheny or Sunset resvr. site, 5500 feet, 16-inch	23,000
Booster equipment and building	7,500
Possible aeration plant	25,000
Additional land for reservoir and reservoir at elevation of Reservoir No. 1	100,000
Miscl. pipe connections to east and west mains	7,500
Engineering and contingencies	28,000
Total	$ 250,000
Extension of Present System:	
Well sites, rights of way, litigation, etc.	$ 50,000
Two to four wells including pumping equipment, housing..$16,000 to	30,000
Collection mains 5,000 to	10,000
Booster pump and housing	6,000
Possible aeration	25,000
16-inch pipe line, booster site to southwest corner of city, 14,000 feet	42,000
300,000-gal. tower 55 ft. high and site	20,000
14-inch pipe line. Above tower to proposed new school site, 6500 ft., 14-inch, and site	40,000
Connections to east and west mains on Carmelita, Elevado and Lomitas	5,000
Engineering and contingencies	30,000
Total	$ 258,000
Water Treatment Plant:	
Additional land	60,000
5 M. G. D. filtration plant, including addition to aeration and plant to rid H2S gas	140,000
Experimentation	10,000
Engineering and contingencies	18,000
Total	$ 228,000

Report on Meter Maintenance Methods Gives Data on Current Practices

By J. H. FAGG

San Joaquin District Manager, Pacific Gas and Electric Company

FOR the purpose of this report a survey was made by means of a questionnaire returned by twenty-eight water companies in California, whose services were metered 80 per cent or over, and involving a total of approximately 640,000 services.

Of these twenty-eight, thirteen plants were municipally operated, and fifteen operated by private companies.

The questionnaire produced the following information:

(1) Fifteen companies check all new meters for accuracy upon receipt.

(2) Twenty companies use the round reading dials, and cubic foot, with one exception, is the unit of measurement.

(3) Only five are continuing the use of compound meters.

(4) Fifteen of the twenty-eight are using batteries of small meters on the larger services.

(5) But three of the companies test their meters periodically: one on two-year schedule, one on a 3-year schedule and one every 4 or 5 years. Also 2 remove their meters for test and overhauling after one complete revolution of the dial.

(6) Practically all of the companies use the concrete meter box and set meters just inside of curb line where mains are carried in the street.

(7) Eleven of those reporting are employing check valves to prevent hot water damage and bill consumers the cost of repairing the damage caused by hot water.

In analyzing the return on the questionnaire it appears that most of the companies realize the importance of testing new meters when received, and from the tone of some of the statements it is believed that it will soon be general practice to test all meters periodically.

The round reading registers are giving the best satisfaction as they will operate over longer periods than will the straight reader.

The use of compound meters is being discontinued rapidly by nearly all of the companies, and the use of batteries of small meters on large services is becoming popular with most Waterworks men.

A very small percentage of those reporting are making a practice of testing meters in the field, and they have equipped their shops with standard test tables of standard manufacture and other necessary facilities for proper handling of meter repairs.

Solving the Water Allocation Problem

(*Continued from Page 12*)

of irrigation benefits. With the total valuation on a basis, a tax rate is calculated to meet the budget with the legal required 15 per cent excess, and tax bills are prepared accordingly.

Naturally, some tax accrues unavoidably against "waived" lands but, with the nominal valuations set, it is trivial, and the general benefits easily compensate. As a practical convenience to the land owner the tax collector in preparing his tax bills shows the "waived" areas as a separate item with the corresponding tax.

To meet the water charges, which are not included in the budget, a *pro rata* flat charge per acre sufficient in the aggregate to meet the payment due to the San Diego County Water Company for the quota of water accruing during the following season, is made against each irrigable acre or lot; i. e., with "full water rights." Notice is given to the land owners by publication that this water toll may be paid in cash by a certain date, and if not so paid will be added to, and become a part of, the tax bill and a lien against the land. The practice is, as was expected, that these tolls are universally made a part of the tax bill and collected with the regular district taxes. Ample warrant for this procedure is contained in the statutes.

As heretofore stated, there is a 10 per cent annual step-up of water deliveries by the Water Company, so the district, therefore, tolls the land owner progressively for one-tenth of an acre-foot per year. For 1927, on the basis of 13,600 acre-feet originally purchased on graduated deliveries, the water allotment would be 2-10 acre-foot, which amount, on cost basis of $17.50 per acre-foot, would give a toll of $3.50 per acre. Since the district has acquired an additional thousand acre-feet, which is not on a graduated scale, but on a straight purchase basis, a *pro rata* of this amount has to be added to the quota stated, with a corresponding additional toll, giving a total water credit of 0.27 acre-feet and a charge of $4.50 per acre. The land owner then has a credit of 0.27 acre-foot of water to be used by him or not, as he sees fit. Eventually a plan will be formulated for the district to resell any unused water allotments to those requiring larger amounts, which will prevent the undesirable "peddling" of unused water. In case of a demand for it, the district may at any time procure from the water company additional water above the regular scheduled quota for that year up to the full contracted amount of 14,600 acre-feet.

Waived Areas Not Excluded

Although seemingly desirable at the outset, for obvious reasons it was found impractical to remove or exclude from the district these "waived areas," for if this had been done a "Swiss cheese" effect would have resulted. Being still legally within the district, these "waived" lands are not precluded from using water as would have been the case had they been removed, for the statute prohibits water deliveries outside an irrigation district. The district board now grants, on application, a permit for one-year periods to an owner of "waived" lands to use such water as he can spare from his fully watered lands, or that he may procure from non-users or surplus water of the district, and time is demonstrating that these areas will absorb considerable surplus and otherwise unused water until maturing orchards, etc., take up the full quota.

Furthermore, as development proceeds and lands are being more carefully examined, many acres of "declassed" lands are proving desirable for some particular use, and a marked tendency is already manifest toward a permanent transfer of water from less desirable fully watered tracts to these "waived" areas, which the board permits after careful scrutiny. The result is that an economic balance is evolving,—the water burden gradually shifting from lands that can not support the charges, to lands that are better suited to do so, due to the fact that there is an excess of lands competing for a fixed amount of water. The danger of the piling up of delinquent taxes on worthless or unused lands, which frequently proves serious and disastrous, will be avoided in the Vista Irrigation District under the play of economic forces afforded by this novel situation and its successful solution.

Current Meter Notes

Hydrometry has made little advance as compared with other branches of hydraulics, the reason for this, perhaps, being the difficulty of analyzing the forces that actuate current meters.

Smoothly flowing water can be measured by means of current meters with

a high degree of accuracy unless the velocity is too slow, but when the flow of a stream is turbulent to such a degree that it is difficult to hold a meter rigidly in the position least obstructing to stream flow—which is essential to reliable meter work—accurate measurements can not be expected.

All current meters will give coinciding results in smooth, evenly flowing water, when the relation between position of rotor axis and the direction of flow is definite and constant and the meter position is normal—the position which is maintained during calibration. Only under such conditions will results obtained by different types of meters or by different meters of the same type agree.

In reality, smoothly flowing water, where stream filaments move continuously parallel to each other, are rare if they exist at all. Although the appearance of the surface may indicate this condition, as a rule it will be found that below the surface the water is moving in varying directions. A meter can not respond to such forces in the same manner that it would to stream forces as they exist where water conditions are ideal, such as are artificially maintained at rating stations for the purpose of giving a meter its rating.

The question has been raised: Why not, then, rate the meters under conditions identical to those in which they will be used? The answer is simple,—there would be no base to the calibration unless a wide range of stream velocities were accurately preestablished.

It is natural that different types of current meters will be differently affected by forces of non-parallel stream lines. It is natural also that the makers of the different types of meters insist that their respective products are the most nearly perfect. The hydrographer will have to decide how a meter should be designed to meet best the prevailing conditions in order to produce most satisfactory results.

Since stream conditions as well as meter operations are never perfect, the solution of the meter problem will necessarily be a compromise. Nevertheless advantages and disadvantages in meters can be readily recognized when it is considered that the meter which offers least obstruction to the stream flow and at the same time is capable of a high rate of rotation, can not fail to be a reliable instrument. It is earnestly recommended that the meter's rating curve be examined in order to verify the good qualities which the appearance of a meter may suggest. A straight line curve of steep slope, connecting a large variety of rating points, is definite proof of quality.

HYDRAULICS

By Joseph N. Le Conte

Professor of Engineering Mechanics, University of California

A thorough Textbook on the theory of hydraulics and on the principles of hydraulic machinery. This book aims to show the student of hydraulics and irrigation how problems in hydraulic engineering can be reasoned out and solved by practical appeal to first principles.

348 pages. 5¾ by 9. Fully illustrated with diagrams and charts. All orders should be accompanied with cash. Allow ample time for shipment from the publishers. $3.00 postpaid.

WATER PURIFICATION

Water Improvement Lies in the Study of Biological Control of Reservoirs

Amount of Work Done by Living Plants and Animals is Astonishingly Great in the West

By DR. CARL WILSON

Director of Biological Laboratory, Los Angeles Bureau of Waterworks and Supply

WHETHER he anticipates it or not, the engineer who constructs an impounding reservoir for domestic supply is confronted with a problem, or rather, an unending variety of problems, in economic biology. The idea that he is dealing only with engineering structures and a chemical called in common language "water," was shattered years ago, but it is only recently that the waterworks superintendent seriously attacked the living causes of his troubles on the one hand, or encouraged his aquatic friends on the other.

Rarely does a water consumer have any conception of the important part which living organisms play in the quality and safety of the water which he uses so freely. He has a vague, and often erroneous, idea that running water purifies itself, and he is aware that disease may be caused by polluted water, but he is not likely to realize that both effects are due to living things. The observing housewife whose kitchen tap brings her water which has passed through one or more large reservoirs, may have noticed that the water is softer at the end of summer than it was in spring, but she would never guess that this difference is due to the untiring activities of microscopic plants. The waterworks engneer who is troubled with evil smelling and testing water, or who is tormented by hordes of insects in his lakes, knows only too well how important is a knowledge of biology.

West's Varied Problems

In our semi-arid climate, where we are compelled to store immense volumes of water for long periods, and where we have the maximum amount of sunshine, with accompanying high water temperatures, biological problems are not only more varied than in the East, but also more intense and trying. Even the stratification of water in a large storage reservoir, due to temperature differences between the top and bottom waters is more pronounced here, because reservoirs often received no influx of new water for months at a time. All summer long and far toward winter, the surface layer of the water will be enough warmer than the rest to prevent mixing with water lower down unless wind and wave action should be unusually effective.

RARELY, points out Dr. Wilson, does a water consumer have any conception of the important part which living organisms play in the quality and safety of the water which he uses so freely. He has a vague and often erroneous idea that running water purifies itself, and he is aware that disease may be caused by polluted water, but he is not likely to realize that both effects are due to living things. The observing housewife whose kitchen tap brings her water which has passed through one or more reservoirs, may have noticed that the water is softer at the end of the summer than it was in spring, but she would never guess that this difference is due to the untiring activities of microscopic plants. The waterworks engineer who is troubled with evil smelling and tasting water, or who is tormented by hordes of insects in his lake, known only too well how important is a knowledge of biology.

As a result of this condition, bacterial activity on the organic matter present in the water and in the bottom ooze, quickly absorbs all the free dissolved oxygen, and further bacterial activity must necessarily be of an anaerobic type, with the inevitable production of foul smelling decomposition products which are characteristic of stagnant water. Generally, hydrogen sulphide is one of these products.

We are told that the thermocline, or line of separation between the deeper, colder, stagnant water, and the upper, warmer, layer of aerated water, lies at a depth of 30 to 35 feet, but in most of our Southern California reservoirs it is likely to be much nearer the top, while in at least one lake with which the writer is familiar it is frequently only ten feet below the surface.

Since the production of objectionable odors in this case is wholly the result of living organisms, the solution of the problem must be a biological one. The answer is, furnish enough oxygen to make anaerobic activity impossible, as bacterial by-products produced in the presence of sufficient oxygen are relatively inoffensive. Complete control of this condition has been obtained in the Lower Franklin Reservoir, on the Los Angeles aqueduct system, by introducing the inflowing water through a pipe lying on the bottom of the lake, and extending from the upper end to within a short distance from the outlet tower. About every 100 feet along this pipe 4-inch openings are provided which shoot jets of water upward, and these jets not only bring to the bottom of the lake a supply of water which is saturated with oxygen, but they also keep the entire body of water in a constant state of circulation. Stagnation never occurs in this lake, and water from the bottom is always as sweet as that at the top.

Lower Franklin reservoir is about a mile long, very narrow, and some 70 feet deep at the dam. Because of its shape, this method of providing circulation is especially effective. The same procedure in Stone Canyon reservoir, which reaches a depth of nearly 200 feet at maximum, is successful, but not to the same degree as at Franklin, due to the greater width and the presence of two large arms which cannot be reached by the pipe system as installed.

Plankton Growths

Plankton growths in reservoirs afford an outstanding example of the need for control measures, and the methods adopted for their repression are familiar to waterworks men, as they are almost universally practiced upon open reservoirs. Sometimes, however, algae may be useful, and the destruction of such a growth is not always advisable.

On the Los Angeles system we have a reservoir covering an area of about 100 acres, with a maximum depth of 45 feet, and impounding 700,000,000 gallons, which illustrates the point. Three years ago this lake was drawn down to a small pond of about five acres extent, in order to make some changes in the outlet, and the exposed bottom ooze gave off sufficient odor to cause complaints from some of the nearby residents. To satisfy these people the lake bottom was plowed over and fresh, clean earth turned over the ooze, making virtually a new bottom for the reservoir.

(Continued on Page 48)

Chlorination

Manual Control Solution Feed Chlorinator—Type MSP
A new rugged apparatus in which the Chlorine is measured under a Vacuum

has become standard practice for the sterilization of water,—the sanitation of swimming pools,—the disinfection of sewage,—the elimination of noxious odors,—and for many other purposes,—largely because of the accuracy and reliability of W&T Chlorine Control Apparatus.

¶ Chlorination of drinking water is not only unsurpassed community health insurance but it is downright good business insurance,—in view of the recent tendency of the Courts* to award damages to persons stricken with intestinal disease caused by polluted water.

*See Engineering News Record, Vol. 97, No. 1, p. 30.

Postpone Water Case Hearing

Final allotment of water from the San Jacinto River, California, has been postponed until May 10 next, in accordance with the request of two of the interested companies. The application for a postponement was made by the Lake Hemet Water Company and the Fruitvale Mutual Water Company which are to be merged into one, the Hemet San Jacino Water Company. It was because of this merger that the delay was asked, according to W. H. Pawson, official of the new company. Two years ago conflicting claims to the water flowing in the San Jacinto River led to an extensive investigation by engineers under the direction of Edward W. Hyatt, chief of the division of water rights. With the results of the survey, Hyatt made a tentative allotment of water to five separate concerns with the understanding that this apportionment was subject to change. Controversy among the companies centers largely around the disposition of a relatively small portion of the water that at present is not being used, according to Hyatt.

SEWAGE DISPOSAL

Chicago Has Biggest Sewage Treatment Problem of Any U. S. City

CHICAGO is confronted with a larger sewage treatment problem than any other city in the United States. Probably few even of its own citizens realize the extent of the work which has been done, is being done, and is contemplated as one of the future necessities. The sewerage of the city and immediate vicinity is in charge of a board of trustees of a district known as the Sanitary District of Chicago, which board raises its own funds for meeting the necessary expenses by taxation.

In 1925, the United States Supreme Court decided that it rested with the Secretary of War to control the amount of water which could be withdrawn by the sanitary district from Lake Michigan for diluting the sewage in the drainage canal, and the Secretary granted a five-year permit for withdrawing 8,500 cubic feet per second, conditioned upon the performance by the district and the city of Chicago of certain obligations, of which the most important were the vigorous prosecution of a program for artificial sewage treatment, the metering of the Chicago water supply, and the construction of flood control gates in the Chicago River.

Comprehensive Plan

In 1923, the Illinois legislature amended the enabling act of the Sanitary District and required that sewage treatment works be put in operation annually, beginning with 1925, at the rate of 300,000 persons per year until provisions had been made for approximately 1,800,000 population. The requirements connected with the permit issued in 1925 by the Secretary of War imposed additional requirements and a program was prepared in five-year periods looking toward the ultimate completion of a system of intercepting sewers, pumping stations and treatment works whereby all the suspended solids will be removed and the liquid pollution so reduced biologically that the main channel and Illinois river will be cleaned up.

In July, 1925, the Illinois state legislature granted the district 1 per cent additional bonding power for the specific purpose of construction of sewage treatment works and adjuncts and for settlement of Illinois valley overflow claims. The district shortly thereafter submitted to the United States engineer a definite construction program calculated to fulfill the requirements of the permit, which was approved on July 28, 1926. During the year the district completed work amounting to approximately fourteen million dollars, and during the last half of the year awarded contracts totaling over eight million dollars.

Big Sums Involved

A bald list of the work under contract and which should be started in the near future occupies 3 1-2 printed pages. Some of the more important items are as follows: Under Contract—North side intercepting sewer, $1,799,000; north side sewage treatment works, $4,005,000. Completion of projects under way—North branch pumping station, $3,000,000; Calumet sewage treatment works additions, $3,693,000; north side sewage treatment works, $3,530,000.

Work which has not yet been started but should be begun this year includes the west side intercepting sewer, $15,800,000; Salt Creek intercepting sewer, $1,500,000; Oak Forest outlet sewer, $600,000; industrial wastes intercepting sewer, $850,000; west side treatment works, $13,410,000; southwest side sewage treatment site, $500,000.

There will be needed in the future although not immediately, a Racine Avenue pumping station, $3,000,000; southwest side intercepting sewer, $8,800,000; southwest side sewage treatment works, $7,200,000; north shore intercepting sewer extensions, $1,000,000; power service for north side sewage treatment works, $5,000,000, and various other items of under one million dollars each.

Engineer Reports on Progress

In reporting on this work the chief engineer, E. J. Kelly, describes briefly the condition of each of the various projects on January 1, 1926. The Calumet intercepting sewer system is practically completed and is receiving all the dry weather flow from the territory served. The North side intercepting sewer, the main feeder to the north side sewage treatment works, should be completed simultaneously with such works. Part of this sewer was completed in 1922 at a cost of two million dollars, providing an outlet for the sewage of the city of Evanston and the north shore towns up to the Lake County line. Another section of this sewer was about 96 per cent completed on January 1, while a third section had not yet been contracted for and five other sections are in various stages of construction.

The North Side sewage treatment works, designed to treat all the sanitary sewage originating in Chicago north of Fullerton Avenue, together with the sewage from the north shore towns to the Lake County line, will have a capacity to handle the sewage of more than 800,000 people. The total cost is estimated at about thirteen and a half million dollars. On January 1 the tanks and galleries were 93 per cent completed, the thickener mechanisms 99 per cent, sluice gates and aeration plates were entirely completed, centrifugal pumps 96 per cent complete; while of other items such as meters, blowers, electrical equipment, grit chambers, air conditioning equipment, pump and blower house and other details, none was more than 46 per cent completed and the pump and blower house had not yet been started. The completion of this work by 1928 is the most important duty of the trustees.

The North Branch sewage pumping station is a necessary link in the north side intercepting sewer system and will replace the existing Lawrence Avenue pumping station with a larger station, electrically operated. It is estimated to cost about $1,300,000.

Running to Capacity

The Des Plaines River sewage treatment works are already handling somewhat more sewage than it was designed for and should be enlarged at once. Future enlargement was provided for when the works were built and ample land is available. The estimated cost of the enlargement necessary is $325,000 with an additional $75,000 for a sludge line.

The Calumet sewage treatment works have almost reached the point where additional biological treatment is needed and it is proposed to install trickling filters following the Imhoff tanks; also additional sludge drying beds. It is also recommended that experimental work to aid in devising or selecting machinery for cleaning sludge drying beds should be installed at the Calumet works; also tests made of devices for indicating sludge levels in settling tanks before their actual use in the North Side sewage treatment works.

The Calumet sewage treatment works have been in operation since September, 1922, and the Des Plaines river works since August, 1922, the sludge press and dry house of the latter having gone into operation in October of that year. In the Calumet works an Oliver filter is used and in the Des Plaines works a Berrigan press and Worthington press. The Morton Grove sewage works are now in good operating conditions as are also the Glenview sewage plant and the North Brook sewage plant, the last of which was put in operation in April, 1926.

The next step in the sewage treatment program of the district is the construction of the West Side sewage treatment works which will serve that part of Chicago north of the south branch of the main channel not served by the North Side works, together with the Loop distict and some territory immediately adjacent thereto. Preliminary studies have been made for these works and borings and test pits sunk to determine soil conditions. This plant will consist of Imhoff or double deck tanks with a sewage pumping station, grit chambers, drying beds, etc. It is being designed to handle the sewage of 1,850,000 people in 1940, including the transient population of the Loop district.

At the Waterworks Convention

Those visitors at San Diego, who went with an eye open for new and practical information on meters found a great deal to intrigue them. The leading manufacturers of water meters were represented by attractive booths, with several experts in attendance to explain the mechanical features of the different makes. Among the meter exhibitors was R. W. Sparling, of Los Angeles. Mr. Sparling personally had charge of the booth.

Wallace and Tiernan Company's "Chlorine Ions" put on quite a spread at the informal convention dinner, Thursday evening at the Hotel San Diego. Among their many guests were the following well-known engineers of the waterworks fraternity:

Dr. Carl Wilson, Los Angeles Dept. of Waterworks and Supply; Harry Reinhardt, Asst. Gen'l Mgr., East Bay Water Co.; W. F. Langlier, Asso. Prof. Sanitary Engineering, University of California; Ray F. Goudey, Sanitary Engineer, State of California; C. G Gillespie, Director, Bureau Sanitary Engineering, Oakland.

E. A. Reinke, University of California, Berkeley; R. G. Wueste, Supt., Impounding System, San Diego; W. M. Starkey, Supt., San Bernardino Water Dept.; Geo. S. Hinckley, City Engineer, Redlands, Calif.; Dr. Lieson, San Diego Health Dept.; John L. Perhab, Water Supt., Calexico, Calif.

Graydon Oliver, Modern Irrigation; Paul A. Diehl, Cons. Engr., Black & Veatch, Los Angeles; C. A. Smith, Burns-McDonnell-Smith Eng. Co., Los Angeles; R. L. Derby, Sanitary Engineer, Salisbury-Bradshaw-Taylor, Engineers; R. D. Whitacre, Supt. Tucson Water Dept.

C. T. Henderson, Chairman, Water Commission; G. T. Luippold, A. L. Frick, Jr., and Alexander Bell of Wallace & Tiernan Co., and Geo. H. Bragg, Chief Engineer, Pacific Gas & Electric Corp.

You *Name the* Load
We *Make the* Pipe!

SINCE concrete pipe (as made by Bent) came into its own, engineers question no longer its striking advantages for a great variety of uses. *But*—a concrete pipe installation is either a mediocre or an eminently superior job of work, depending upon who fulfilled the contract.

Many trade names have become hall-marks of tradition, that serve as an unerring guide to discriminating buyers. Today the name "BENT" on a joint of Concrete Pipe marks it as a strictly finely made product. The same care and skill is exercised in its manufacture, and in the laying of the line, as though every future contract depended on *that* job meeting the fullest requirements of specifications—*and more.*

Let us give you a "concrete" demonstration of what we mean by "Bent" Service.

Fifty Years of Progress in Sewage Disposal is Tribute to the Scientist

IT WAS just fifty years ago, says Robert Spurr Weston in Industrial and Engineering Chemistry, that Colonel George E. Waring, Jr., described a closed tank for sewage treatment which he had built at Newport, R. I., and in which "the solid deposit of organic matter decomposes in the form of ammonia, which helps dissolve the grease and make it soluble so that both the deposit and scum are constantly wasted." This tank had its prototypes in France and elsewhere. Its modern representative is the septic or biolytic tank, improved in this day by separating digestion from subsidence, using two-storied tanks like the Imhoff tank, or separate digesting tanks as recommended by Clark and used successfully at Baltimore.

The digestion of sewage solids by hydrolysis is due to various groups of anaerobic bacteria which were not known fifty years ago and were not studied carefully until this century. At the present time these useful deoxidizing organisms, and the conditions under which they will best function, are better understood, even though much work remains to be done.

The contact bed is practically a tank containing a coarse contact medium (broken stone) and filled with sewage, emptied, and rested in cyclic order. It combines oxidizing and deoxidizing functions; that is, it both liquefies and nitrifies organic matter. Furthermore, because of the large surface in contact with the sewage, it furthers clarification. It is less used than formerly, although it produces better effluents than are produced by plain subsidence or screening. It is now used chiefly either where a high degree of purification is not required or preliminary to intermittent filtration through sand.

The trickling filter of coarse material over which sewage is sprayed or otherwise distributed mechanically is a development of thirty years. It is the result of trying to expose sewage in thin layers to a large contact surface, alive with aerobic bacteria and well aerated. Usually this device produces a nonputrescible effluent, turbid with humus-like matter, which latter is usually removed by the secondary subsidence before the final discharge of the effluent. A recent development at Fitchburg, Massachusetts, and elsewhere, is the return of this humus-like sludge to the Imhoff tank, which precedes the filter.

BASKING IN SAN DIEGO'S SUNSHINE AT THE WATER-WORKS CONVENTION

Top, left to right: Wm. Mulholland, chief engineer; Wm. W. Hurlburt, office engineer; Jas. E. Phillips, asst. engineer, all of Los Angeles water department; and L. N. Slater, manager Western Pipe & Steel Co.

Center: Alexander Bell, Wallace & Tiernan Co.; C. T. Henderson, Great Western Chemical Co.; A. L. Frick, Jr., Wallace & Tiernan Co.

Bottom: Andrew Ervast, chief engineer, Spreckles Co., San Diego; Virgilio Bruschi, city councilman, San Diego; A. P. Lovell, superintendent water department, San Diego; R. W. Martindale, U. S. Cast Iron Pipe Co.; and J. J. Swenson, American Cast Iron Pipe Co.

Activated Sludge Process

The activated sludge process was developed by Clark at Lawrence, Massachusetts, and by Fowler and his associates at Manchester, England, and was improved in principle by Bartow, Mohlman, Pearse, Hatton, Copeland, and others. It consists, in brief, in agitating sewage in contact with air and an accumulation of its own sludge. It is the acme of treatment by oxidation. The sludge particles, bearing nitrifying and other bacteria, circulate through the liquid, causing both flocculation and oxidation. Separation of sludge in the effluent is effected in tanks or clarifiers, the latter device being an adapted ore-dressing machine. The effluent from this process is excellent.

Mention must be made of the development in the way of preliminary treatment by screens, grit chambers, or subsiding basins, without which the operation of filters and activated tanks would be difficult. Practically all these devices, with the exception of plain subsiding basins, have come into use within fifty years.

Precipitation By SO_2

By adding lime and other chemicals the precipitation of organic matter may be accelerated. This process has come and largely gone during fifty years. Precipitation by sulphur dioxide has been suggested by Miles. It produces a partially disinfected sludge of low water content and high in recoverable fats and potential fertilizer value. The practicability of recovering the fats and fertilizer from this awaits research.

Supreme Court Holds City Liable in Typhoid Damage Suit

Washington State Tribunal Rules That Lack of Proper Inspection Constitutes Negligence by Municipality

"There are a few leading cases," says the Nation's Health, "in which compensation has been granted workmen for disease such as typhoid fever contracted through impure drinking water furnished in places of employment. Instances where damages have been awarded against a city for similar offenses are rather unusual. For this reason, the two following citations are of interest to health workers. They both apply to the same period of pollution but different legal points are cited in each case.

"The facts upon which claims were based (Aronson vs. City of Everett, Supreme Court of Washington, 239 Pac. Rep. 1011) were that the city of Everett, Washington, permitted access of polluted river water to the city mains which was consumed by different citizens, some of whom contracted typhoid fever with fatal results. The pollution entered the city mains through a cross connection in one of the local mills. This bypass was guarded by the usual check valves and a gate valve. Usually the pressure in the city mains was higher than that in the water system of the mill. Also, the gate valve was supposed to be kept closed at all times.

"It was subsequently found that during the relaying of some new pipe this valve had been left open, permitting access of the polluted river water to the city mains.

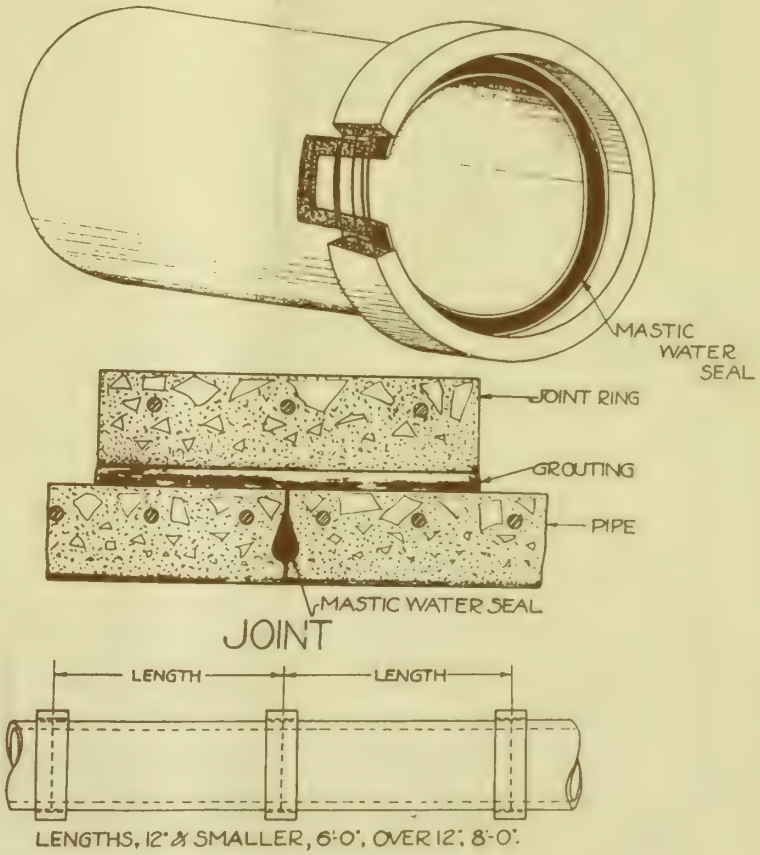
Holds City Negligent

"Under the case at issue, Mrs. Aronson contracted typhoid fever and her husband brought suit for damages against the city in which he obtained a verdict of $6,000, apportioned $2,000 to each of two children, three and six years of age, and $2,000 to the husband.

"On appeal it was contended that the city could not warrant absolutely the purity of the water, but the court held that the city was negligent in not protecting its supply from pollution. In dismissing this contention the court said that while former cases cited by the appellant 'hold that a city furnishing water to its inhabitants does not impliedly warrant that the same is pure and wholesome, yet both these cases recognize that the failure to properly inspect the water so as to keep it free from contamination is negligence. There is ample authority that a city engaged in furnishing water, electricity, or other kindred services to its inhabitants for a profit is liable for negligence the same as any private corporation engaged in the same business,

Centrifugal Reinforced Concrete Pipe

Spun by the Hume Process



Introduced Now in the West for High Pressure Pipe

This pipe is impervious to soil corrosion and free from leakage at high pressures. Tests show unit tensile strength in excess of 400 pounds per square inch, which is double that of the best concrete by old methods.

We are prepared to furnish and lay Hume Concrete Pressure Lines. Prices upon application.

that the city does not act in a governmental capacity, and that there is an implied warranty that the water is fit for human consumption. . . . As to which rule should be adopted it is not necessary for us to determine in this action, since we hold the complaint is based upon the ground of negligence and not on implied warranty.'"

Two Measures Advised to Check Siltage of Reservoirs

U. S. Forest Service Advocates Planting of Trees and Establishment of Settling Basins

The Department of Agriculture, through the Forest Service, has called attention to the danger to water-power and water-supply development through erosion and silting up of reservoirs. The planting of protective woods and the establishing of settling basins are two of the preventive measures advocated.

The full text of the statement follows:

Suggestions that may add to the value of waterpower and water-supply developments are made in a bulletin just issued by the Forest Service, United States Department of Agriculture, entitled "The Financial Limitation in the Protection of Reservoirs,'" by W. W. Ashe. It is of interest to investors of such properties and to engineers.

Siltage Reduces Ponds

Storage of water is becoming a recognized factor in hydroelectric development, just as it is necessary in most cases for municipal supply. This bulletin shows that with storage there enters the problem of siltage through erosion of soil, an insidious agency which may cause loss of pondage and consequent reduction in the capacity of reservoirs.

The rapidity of erosion and of silting up of reservoirs is affected by different physical and meteorological conditions in the different regions of the United States. Over the greatest portion of the northern and northwestern United States and in Canada erosion is not the serious problem that it is in parts of the southeast and particularly in portions of the southwest.

The bulletin calls attention to the high silt burden of certain streams and the rapidity with which storage capacity of reservoirs is reduced, as in the case of the Colorado River (of Texas). The reservoir at Austin on this river lost more than its capacity within ten years.

Many other streams carry a silt burden fully as great as that of the Colorado. On the basins of certain of these streams, according to Mr. Ashe, the surface conditions are such that erosion can be only slightly lessened. On these it is a natural condition, the result of con-

For Detailed Listings, Branch Offices, Etc., See the Buyers' Guide to Leading Supply Sources—Page 67

centrated rainfall on surfaces naked of protective vegetation on account of irregular rainfall. There are other regions, the bulletin points out, where protection of the surface is highly efficacious in reducing erosion.

Silting Can Be Measured

It is shown that it is possible to ascertain the rate of silting which is taking place and from this to determine the capital value of the storage capacity, the loss of which might be expected within a given period. It is also possible to determine the extent to which excessive erosion may be checked by artificial means.

Mr. Ashe proposes a formula for determining how much money could be economically expended to maintain this capital value, which otherwise would be destroyed by siltage. He points out that in case woods are artificially established for the purpose of securing soil cover and reducing erosion a definite return can be expected from the investment therein, but that power and water companies are justified in making additional expenditures which would be within the capitalized value of the storage capacity which will be preserved.

In the Southern Appalachians as well as elsewhere there are alluvial lands which have been injured during floods by gullying or by the deposit of sand and gravel. Where such conditions exist there is, in the opinion of Mr. Ashe, an opportunity for the establishment of settling basins.

Settling basins of the kind he proposes would not only result in the elimination of much silt from the stream but also would bring about the rehabilitation of the devastated lands, which, after being built up by deposit of the sediment, would again be available for farming. Since this sediment as a rule consists largely of the most fertile soil eroded from the surface of the watershed, areas thus built up would be very productive.

Copies of the bulletin, which is designated as Department Bulletin 1430-D, can be obtained from the Forest Service, United States Department of Agriculture, Washington, D. C.

Ralph R. Woolley, a hydraulic engineer of Salt Lake City, Utah, is now editing the Utah Engineer, a new periodical published in the interests of Utah engineering. Mr. Woolley has at various times been connected with road material tests and a number of hydroelectric and irrigation investigations. Since 1917 he has been connected with the U. S. Geological Survey, classifying public lands with regard to water power and irrigation possibilities.

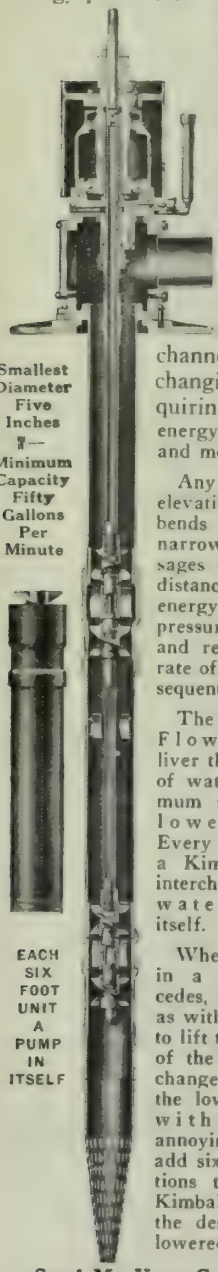
ITS NOT in the HEAD--- ITS IN THE PUMP!!!

The head transmits the power only. It's the pump in the well that does the work.

The shortest distance between two points is a straight line, and the least energy possible to move anything this distance is over this *direct* course. Any other route requires more energy.



Smallest Diameter Five Inches — Minimum Capacity Fifty Gallons Per Minute

EACH SIX FOOT UNIT A PUMP IN ITSELF

The Kimball pump is a *direct flow turbine.* It carries the water up in a direct, free, unobstructed, even diametered, straight channel, under an unchanging pressure; requiring the minimum energy, for the greatest and most efficient Service.

Any other manner of elevating water — around bends and turns — thru narrow and wide passages — lengthens this distance, requires greater energy, creates uneven pressures in the pump;— and results in a lowered rate of efficiency and, consequently, higher cost.

The Kimball Direct Flow Turbine will deliver the greatest capacity of water, from the minimum sized well, at the lowest operating cost. Every six-foot section of a Kimball pump is an interchangeable, complete, water lifting pump, in itself.

When the water level in a Kimball well recedes, it is not necessary, as with other type pumps, to lift the entire pump out of the well to make the change necessary to reach the lowered water level, with the accompanying annoying delay. Simply add six-foot pumping sections to the top of the Kimball pump, adding on the desired length to be lowered, does the job.

The Biological Control of Reservoirs

(Continued from Page 40)

Following this, the steep sides, which were subject to storm wash, were oiled and rolled with a view to prevent cutting. When the lake was filled there was no vegetation of any kind below the flowline, and the incoming water was all filtered. Black bass, blue perch, and carp stocked the lake, and multiplied rapidly. Here was a clear case of unbalanced biological conditions—all animal life. Naturally enough, plankton growths appeared, and they were held in check by the usual copper treatments, but in spite of our best efforts the water became stagnant and had to be withdrawn from service.

Briefly, the oxygen demand of the fish population (necessary to keep down insects) was in excess of the supply derived from the inflowing water and from surface absorption, so that anaerobic bacterial activity spoiled the water. Artificial aeration with the compressors was tried, but owing to the area and shape of the lake, it was not a success. Considerable growths of Scenedesmus, one of the green algae, appeared at midsummer, and were allowed to go on unchecked, as the reservoir was out of service, and practically devoid of dissolved oxygen at the surface. Scenedesmus happens to be one of the most benign algae, but candidly, we feared to use copper, thinking it would make bad matters worse.

Algae Save the Day

Contrary to expectation, as the growth increased, the quality of the surface water steadily improved, apparently due to release of oxygen by the green algae as a by-product of photo-synthesis. The plants had saved the day. Since then we have been able to utilize several of the algae in this manner with marked improvement in the upper waters. In fact, this simple expedient has enabled us to retain the lake in service all summer, skimming off the top layers, whereas otherwise it would have been necessary to put the reservoir out of service. Naturally, not all algae can be employed in this way, but generally speaking those members of the Chlorophyceae which are known not to be producers of foul odors, may be used.

Not infrequently birds assume importance on reservoirs, particularly those which send water directly into service. Swallows nesting around an outlet tower have been known to add colon bacilli to water which was otherwise perfect, thus necessitating a chlorine treatment that would not have been required. Obviously the remedy is to prevent nesting about the outlet works.

In Los Angeles we have had several instances where water fowl have carried Peridinium from the brackish sloughs near Wilmington, or perhaps from the open sea, to our distribution reservoirs. This organism is exceedingly interesting and even useful in the ocean, but it is always an unwelcome visitor in reservoirs, because it makes the water rusty red in color, and imparts a most unpleasant odor and taste when the growth finally dies.

Other Bird Offenders

Cormorants are also undesirable about a reservoir, first because they may seriously deplete the stock of fish, and second because of their unclean habits. Like swallows, they haunt the outlet towers and sadly deface the structures. It has been found desirable in Los Angeles to drive them off the reservoirs by shooting.

The worst bird offenders, however, are sea gulls and mudhens. In the fall it is a common thing for 10,000 or more gulls to rest on one of our lakes at night, and the amount of guano which they deposit in the water is sufficient to become a matter of real importance. Probably 30 grams per day per bird is conservative estimate, and when this is multiplied by the immense numbers of birds present it is easy to see how it may effect the quality of the water. Increase in B. coli content is the least serious result, for chlorination may be made to remove these bacteria. The amount of oxygen consumed in the reduction of the fecal matter is great enough to seriously deplete the available reserve, and when this has been done, anaerobic bacterial activity quickly spoils the water.

In the Los Angeles reservoir referred to above, we feel confident that the exhaustion of oxygen has been largely due to birds. Moreover, the fertilizing value of the guano stimulates luxuriant growths of algae, for these plants are quite as susceptible to the effects of fertilizers as are the farmers' crops. To be sure, growing algae furnish free oxygen to aid in the reduction of organic pollution, but many types cannot be permitted to grow long enough to accomplish real aid in this way, for they would give rise to their own peculiar bad tastes in the water.

Economic Control Desired

Because of the complexity of these actions and reactions, the problem of control is far from simple, but even here some benefit is to be derived by pitting the activities of plants against those of animals. So far, however, we have obtained our best results by shooting at the birds sufficiently to drive them from the lake.

[*Send Us Your Pump Problems for Solution*]

WOODIN & LITTLE
PUMP HOUSE
33 Fremont St. : San Francisco

The control of pollution on an impounding reservoir is at once the most important and most difficult of problems in economic biology. It is well to accentuate the fact that what we desire is *economic* control, for the whole solution of the problem hinges upon economy. If natural purification can be depended upon to accomplish the desired results it would be unwise to spend money to do it artificially. Naturally, gross pollution must be removed regardless of cost, but where adequate storage is afforded and draft is made through a distribution reservoir, too much money must not be spent on the impounding system.

Under ordinary conditions it is better practice to regard this branch of biological control as belonging to distribution reservoirs, but of course where one reservoir acts in both capacities, as Sweetwater reservoir, it is necessary to treat the lake as a distribution reservoir and eliminate all possible contamination. This policy has been adopted in the case of Sweetwater, and the company has bought up most of the small holdings around the lake, removing the buildings and holding the land fallow. Continuous chlorination of the effluent is relied upon to provide final protection.

There is one more task which biology may be made to shoulder under some conditions. In the case of a water which is high in temporary hardness, that passes through a large impounding reservoir and subsequently through one or more distribution reservoirs protected by the accepted treatment plants, plankton algae may be made to materially reduce the hardness, perhaps to the entire amount of the temporary hardness. It is well known that these plants are able, after all the free carbonic acid has been removed from water, to attack bicarbonates of calcium or magnesium with the release of half-bound CO_2, which they use as food material. The normal carbonates of these bases, which result from such action, are insoluble, and hence removed from the upper layers of water where photosynthesis occurs.

Careful Study Worth While

Careful study of the biological factors affecting water under storage will undoubtedly show us many new ways of improving water. The amount of work done by living plants and animals is astonishingly great, and means will be found to direct at least part of these activities for the benefit of man. Perhaps one of the most profitable ways in which small funds can be invested is in detailed and intelligent study of fresh water biology in its economic aspects.

Pumps to Praise

Not one or two owners, but hundreds of them have only good words to say for

PEERLESS PUMPS

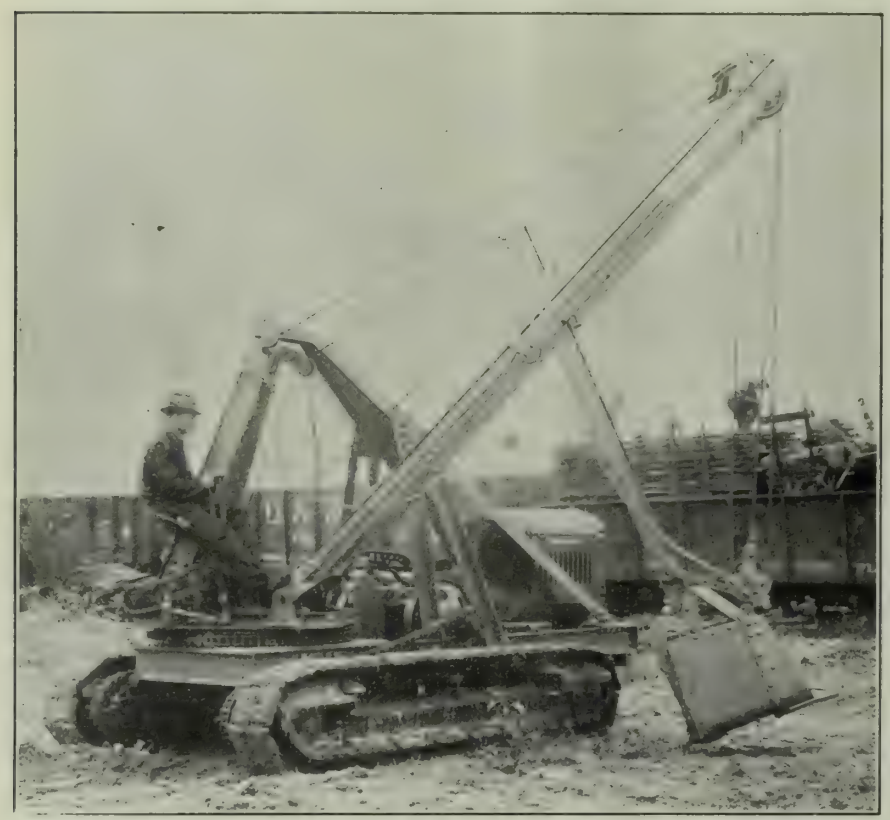
TRADE NOTES *of the* MONTH

THIS TRACTOR SHOVEL BUILT FOR SPEED



A close-up of the new tractor shovel. It is one-man operated and can be run on kerosene

THE Bay City tractor shovel, manufactured by the Bay City Dredge Works, of Bay City, Michigan, is being announced to the public following a period of exhaustive and severe tests. It is the creative work of John W. Fairbanks, designer of note, who has previously developed earlier models of tractor shovels.

This machine is built around the International McCormick-Deering Tractor, which supplies the motive power and provides three propelling speeds—the fastest of which is 3½ miles an hour—through its selective transmission. All of the operating machinery is located on a revolving bull-wheel, which is above the machinery frame.

The operator revolves with the machinery, which swings through an arc of 270 degrees. This three-quarter circle swing permits full circle utility and part circle economy. The shovel can dig or load opposite the rear end of the crawlers.

The machine is built throughout of special steels with alloy shafting; forged, heat-treated and machine-cut gears, and Timken roller bearings. It is equipped with a shovel that will make five bucket trips per minute; and with full-length steel crawler treads 9 feet long, with tread rollers enclosed to keep out dirt. The operating machinery, gears and bearings, are also enclosed under a removable metal hood for protection from weather and dirt.

One-Man Operation

The machinery is strictly one-man operated, and can be run on kerosene if desired. The shovel boom is 15 feet long, permitting the shovel to cut at a height of 17 feet or dump at a height of 15 feet. Crowding is accomplished by means of a steel worm and bronze worm gear running in oil and connected with the machine by shafts and gears. This crowd is reversible and positively self-locking.

The Bay City tractor shovel can be quickly converted into a crane, dragline or backfiller, by removing the shovel boom and crowd and putting on a 25 foot crane boom. Power boom hoist mechanism is provided for either shovel or crane.

The Bay City tractor shovel is intended to fill long felt needs for a light, small and fast convertible excavator for general excavation, loading materials from stock piles, loading or unloading cars, excavating or backfilling small sewers, curb trenches, etc. It is particularly adapted for the excavation of house basements. It can move to a job three miles away in less than an hour's time, and its high propelling speed and compact design make it the ideal machine to use on small jobs where the installation of a heavy, high-priced machine is not warranted.

The dipper capacity is 3-8 cubic yard water level measure, or practically ½-yard heaped. The machine weighs 8 tons, and is capable of digging very hard material.

Issues New Pump Bulletin

Ingersoll-Rand Company has issued a new and revised edition of the Cameron single stage, double suction, volute pump bulletin which describes in detail the three different classes of these pumps. The bulletin is excellently illustrated, showing all the details of the pump, as well as installations in various types of plants.

The Cameron single stage, double suction pumps, as described in the bulletin, are suitable for direct connection to alternating or direct current motor, steam turbine, gasoline engine, or for belt drive.

Would Cure Concrete With Liquid Sprayed on Wet Surface

Experiments With Hunt Process Show That It Has Many Advantages Over Old Methods of Curing

F. W. McRae, chief engineer of the Everlasting Paint and Sales Company, has recently been conducting exhaustive experiments upon the curing of green concrete by means of protective coatings, and has compiled a complete report of the results. It is his theory that new concrete can be properly cured by the application of a protective coating, sprayed upon the wet surface.

This theory is embodied in what is known as the Hunt Process, which is described in Mr. McRae's report as follows:

"The process consists of spraying the sub-grade just ahead of the concrete, which we find prevents the moisture in the concrete from going into the earth. If the contractor starts pouring at eight o'clock in the morning, by eleven o'clock he finds that a certain portion of his pavement has passed the runoff period, when water rises out of the concrete and a slight glaze is noticeable. If the conditions indicate a warm day, small checks appear as the quick evaporation sets in, or if the day is windy the same checks will appear. At that time, with the Hunt Process (protective coating) he could move his spraying machine up to the concrete and cover it with a protective coating which would stop evaporation and, we find, adhere to the wet surface. Possibly by the end of the day he will have protected two-thirds of his day's run. The next morning he can complete the protection of the previous day's run.

Will Remove Grief

"We do not expect this method to cheapen the cost of concrete paving to any great extent, but it will take from the contractor possibly the greater part of his grief, which is the curing and protecting of the pavement after laying. For instance, under the present method the sub-grade is dampened to a point of saturation, which to some extent protects the moisture in the concrete; next, a certain amount of earth must be left for covering purposes. This earth is naturally handled twice, which means expense on yardage; next, as the pavement is laid, the contractor is called upon to protect it from quick evaporation either by light spraying or covering with burlap or canvas, and the following morning a layer of from four to five inches is placed on the pavement by hand.

"This covering as a rule must be completed before noon, which means that the

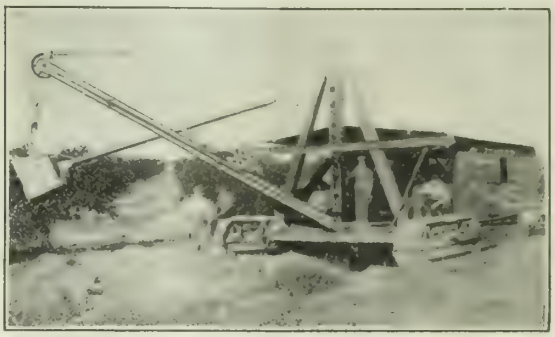
For Cleanout -- Maintenance -- New Ditches

There's a Bay City for Every Job

BAY CITY Land Dredges span the ditch, can dig any desired slope, and dump waste on both banks. BAY CITIES leave clean, wide berms, and can work up or down streams. One trip over the ditch is enough. The Shovel Type Dipper handles hard material in which other types of buckets cannot make a good showing.



At left—One yard BAY CITY Dredge digging and cleaning ditches in Florida Citrus Groves.

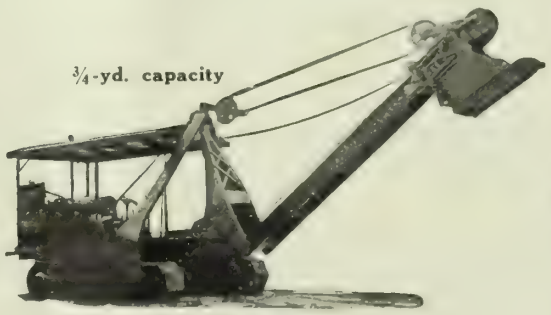
BAY CITY Land Dipper Dredges are built to fit the job. Walking, Crawler, Track or Floating mounting. Easily dismantled, transported and assembled. Capacities ½ to 1½ cubic yards. Oil engine or electric operation.

FOR SMALLER DITCHES — OR PIPE LINE TRENCHES

The BAY CITY 16-B convertible Excavator will handle a wide range of work. Operates Dragline, Trench Shovel, Clamshell or Skimmer. All steel. Shipped assembled. Digs any width or depth up to 20 feet.

STEEL CONSTRUCTION

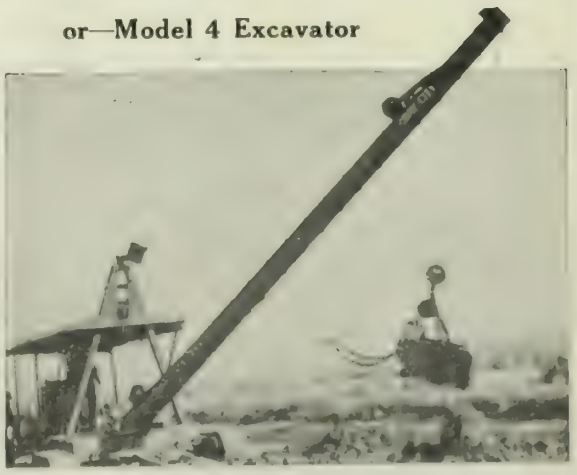
¾-yd. capacity



FULL CRAWLER MOUNTING

or—Model 4 Excavator

BAY CITY Model 4 is a small low-priced convertible, one-man operated Excavator. Fills the gap between hand labor and high priced equipment. Capacity 20 to 40 cubic yards per hour. Gasoline or electric power. A Real Digger economically designed for the small job. Also operates shovel, and clamshell.



One of the Model 4's Owned by Colorado Irrigation Companies. Cleaning Out Canal.

WHO'S *WHO* AND WHO'S *WHERE*

IN THE WORLD OF HYDRAULICS

Personal Notes and Impersonal Observations About Men You Know

B. A. Shumakov, irrigation engineer from Russia, recently visited the Yuma project, Arizona.

George C. Kreutzer, director of reclamation economics, conferred recently with owners of unimproved lands on the Orland project, California.

Glenn F. Engle, assistant engineer on the Newlands project, Arizona, has resigned to devote all his time to his ranch interests.

N. C. Grover, chief hydraulic engineer of the United States Geological Survey, recently visited the American Falls Dam, Idaho.

J. R. Iakish, associate engineer on the Shoshone project, Wyoming, has been transferred to drainage investigations on the Vale project, Oregon.

F. A. Kern, secretary of the Kittitas Reclamation District, Washington, paid a recent visit to reclamation headquarters in Washington, D. C.

T. R. Smith, junior engineer in charge of hydrography at American Falls Dam, Idaho, has been transferred to the Denver office of the Bureau of Reclamation.

B. T. Ploeger, levelman on the Shoshone project, Wyoming, has resigned to accept employment on the municipal water supply works for the East Bay cities, California.

J. J. Doland, assistant engineer in the Denver office of the Bureau of Reclamation, has resigned to accept a position as instructor in the College of Engineering, University of Illinois.

Professor Frank Adams, of the University of California, one of the members of a committee appointed to resurvey the levee of the Imperial Irrigation District, California, has begun preliminary work on the survey.

F. A. Banks, engineer in charge of the American Falls dam, Idaho, has been put in charge of the construction of the Owyhee dam and the canals and water distribution system, according to a recent report from Boise, Idaho.

Dean Phillips S. Donnell, of the University of New Mexico, gave a recent address before the New Mexico Association for Science on the proposed developments of the Middle Rio Grande Conservancy District.

Mrs. Laura E. Varco, named as director for the one-year term in the Snow Creek irrigation district, Oregon, is believed to be the first woman in Central Oregon elected to the board of directors of an irrigation district. She succeeds Paul Scoggin, resigned.

William M. Green, who has been in charge of the investigation of the Great Basin reclamation project in Utah, has resigned his position with the United States Bureau of Reclamation to become affiliated with the J. G. White Engineering Corporation in Mexico.

Stan Spacek, a representative of the Cchezoslovakian Government, is planning a trip, according to a report from the Bureau of Reclamation, that will take in the various reclamation projects where construction is going on, and particularly those where dams are being built.

C. C. Cragin, general manager of the Salt River Valley Water Users' Association, Arizona, made a recent trip to Washington, D. C., to secure approval of a contract for additional sale of electric power which is expected to add $250,000 to the annual revenues of the Salt River project.

M. J. Dowd, according to a report recently received from Imperial, California, has been made chief engineer and general superintendent of the Imperial Irrigation District with jurisdiction over the entire system. Mr. Dowd has been with the district for several years and prior to his appointment as general superintendent had been water master of the system with Calexico as headquarters.

Edward Hyatt, Jr., chief of the division of water rights of the State Department of Public Works at the semi-annual conference of the California Economic Research Council, recently held in Los Angeles, delivered an address on the subject of the relationship of economic research to California water problems.

W. P. Boone, of Dinuba, California, has been chosen chairman of the management board for the Pine Flats project. The other members of the board are: Charles L. Kaupke, Fresno, secretary; Harry L. Haehl, San Francisco; George L. Swendsen, Fresno; E. R. Reed, Reedley; R. E. Shore, Lemoore; and W. H. Shafer, Selma.

H. W. Nicoldsen, of the irrigation service of Punjab, India, paid a recent visit to the Denver office of the Bureau of Reclamation. He consulted with the officials of the bureau with regard to an itinerary for a trip he is planning through the western states to obtain information concerning high dam construction methods.

H. F. McPhail, electrical engineer in the Denver office of the Bureau of Reclamation, has made a recent study of the proposed pumping site at Shell Rock Point, Okanogan project, Washington. According to a report from the bureau, he also ran out trial lines for the proposed pump main from the river to the project canals, and looked over the McLaughlin Canyon dam site and the possibility of storage of water in Osoyoos Lake.

W. P. Davidson, president of the Oregon-Western Colonization Company, has volunteered, according to a report from Burns, Oregon, to underwrite the cost of casing for a thorough irrigation well test. At the same meeting P. S. Weittenhiller agreed to drill the well without immediate advancement of the costs. These proposals are said to make possible the establishment of an eighty-acre demonstration farm in connection with the Harney branch state experiment station for the testing of irrigation possibilities under field conditions.

Buell Dam Contract Let

At a special meeting of the board of directors on October 27, 1926, contract was awarded to Messrs. Kraner & Haskell of San Francisco for the construction of the Buell Reservoir Dam, Montecito County (Calif.) Water District.

This dam, which is to be a hydraulic fill with concrete cut-off wall and Gunite surface on upstream face, will form a storage reservoir of 63,500,000 gallons and is located on the south side of the Coast Range in Montecito, about six miles east of Santa Barbara, and will form an equalizing and storage reservoir on the district's distribution system. The dam will contain about 140,000 cubic yards of earth fill. Construction will be commenced immediately, and it is estimated that about eight months will be required to complete the dam.

Messrs. Leeds & Barnard, 704 Central Building, Los Angeles, are consulting engineers for the district, and Carl Wyant, Montecito, is general manager for the district.

MONTECITO COUNTY WATER DISTRICT

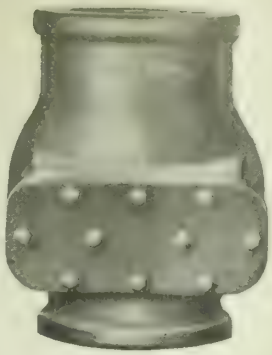
California Water Survey Ready

After six years of work the report on California's water resources will be ready for submission to the 1927 legislature, according to an announcement made by State Engineer Paul Bailey. Authorization for the survey was first given by the 1921 legislature, which voted $200,000 for the work. Subsequent appropriations by the legislature brought the total for the survey to $440,000. Mr. Bailey has not as yet determined whether the report will embody recommendations by his office, or whether the document, containing several plans of water conservation and control, will be presented to the legislature without comment as to the merit of the various schemes. One of the features of the report will be the plan to irrigate the thousands of arable but uncultivated acres in the San Joaquin Valley by the surplus water of the Sacramento River.

Issues Mortgage to Guarantee Payment

Roseville Water Company has been authorized by the California Railroad Commission to file its mortgage guaranteeing payment of $180,000 of bonds heretofore authorized by the Railroad Commission.



"COMMERCIAL" SWING CHECK VALVES

"Commercial," Horizontal or Vertical Swing Check Valves are manufactured in two types, Flanged or Threaded, for Standard Pipe or Water Well Casing as shown in cut.

They are all made with iron body and valve seat and rubber-faced valve. This feature makes them especially fitted for water well use as sand under the valve will not cause leakage.

LEGAL *and* JUDICIAL

A DEPARTMENT CONDUCTED BY HANKINS & HANKINS

Willful Failure to Supply Water Subject to Punitive Damages

An officer of a water company is also liable where acts are done under his direction.

In the case of Gila Water Co. vs. Gila Land and Cattle Co. et al., 249 Pac. 751 (Ariz. Oct. 5, 1926) the plaintiff Land Company, in a trial before a jury, obtains a judgment against the Water Company, and also its president, for the sum of Twenty-Four Thousand Four Hundred Fifty and no/100 ($24,450.00) Dollars, actual damages and Five Thousand and no/100 ($5,000.00) Dollars, punitive damages. The damages arose through the alleged, willful, unlawful and wrongful acts of defendants in depriving plaintiff of the use, during the growing season, of irrigating water. The judgment against the president is supported by the allegation that he personally directed or dictated the willful, unlawful and wrongful diversion of plaintiff's irrigating water.

In upholding the judgment against both defendants and for both actual and punitive damages, the Supreme Court of Arizona states:

"We think it is very well settled that an officer of a corporation who directs and controls its operations is equally liable for the commission of torts by the corporation done under such officer's authority or direction or with his approval. In such circumstances the officer is regarded as a joint tort-feasor. It is urged that there was no evidence justifying the submission of the question of punitive damages to the jury . . . . Exemplary, punitive, and vindicative damages mean practically the same thing, and comprehend damages inflicted upon a party over and above actual damages for the purpose of punishment and as a deterrent . . . . The question is, was the taking and converting of plaintiff's water done with a reckness disregard for, or a willful indifference to, the rights of plaintiff? If from the evidence it may reasonably be concluded or inferred that defendants assumed the attitude of intending to take plaintiff's water, deeming it sufficient justification that they were able to pay any damages that might result therefrom if it should be ultimately determined they had no right to such water, then the question of punitive damages was properly submitted to the jury . . . . Under such circumstances, we think the Court properly submitted the question to the jury to determine whether the defendant's act was wilful and in reckless disregard of plaintiff's rights, or whether defendants acted in good faith believing they were entitled to use the water they took."

Long Continued Use of Ditch Becomes a Right

The fact that claimant contributed to the ditch upkeep is evidence of a definite right in the ditch.

In the case of Miles vs. Fletcher 249 Pac. 781 (Wash. Oct. 8, 1926) the parties using a ditch became involved in a controversy and the upper land owner (defendant and appellant) refused to allow water to reach the lower land owner (plaintiff and respondent). A suit is brought to enjoin any interference with the ditch, and in deciding that plaintiff had a permanent right in such ditch and not merely a "permissive right" the Supreme Court of Washington stated:

"Under these facts it cannot be held that the right to the use of the ditch by the respondents and their predecessors in interest was permissive; but, on the contrary, it must be held that such use for more than the statutory period was under a claim and color of right, and that the appellants and their predecessors in interest in standing by, encouraging, allowing, and permitting the respondents and their successive grantors to expend money and labor in the improvement and maintenance of the ditch puts the appellants in a position that will not allow them to deny the fairness and correctness of the judgment from which they have appealed."

Agreement to Install and Maintain Drain Constitutes an Easement

A purchaser, seeing such drain, is put on inquiry as to agreement for maintenance.

In 1901 two adjoining property owners each built a drain on his own land and then connected the two so as to make one complete drain. An oral agreement was entered into between the parties whereby each was to pay the expense of constructing, maintaining and repairing his own drain. Later, owners of the lower drain changed this drain from wood to tile. In 1918 the upper owner also changed his drain to tile but the lower owner refused to allow him to connect up with the lower drain. A suit is brought to enjoin the lower owner from interfering with the connection of the two drains.

In upholding the right of the upper owner to make such drainage connection, the Supreme Court of Colorado in the case of Schneider vs. Cross 249 Pac. 643; (July 6, 1926) holds on the various points made by defendants as follows:

"Full performance for 17 years of oral agreement by adjoining landowners for the installation and maintenance of a drain takes it out of the Statute of Frauds. Such an agreement creates an easement which will run against the servient estate if the purchaser had notice of it, and a purchaser, knowing of the connection between his drain and that of adjoining land, is put on inquiry as to any agreement for maintenance."

Napa County Decision for Condemnation Held Void

A judge is disqualified to hear a condemnation suit if he is a stockholder in a bank holding a Deed of Trust on the property to be condemned.

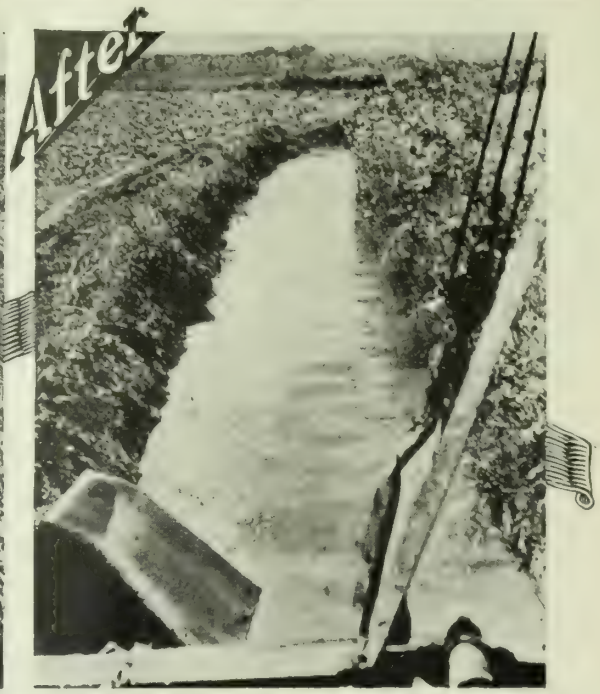
In the case of City of Vallejo vs. Superior Court of Napa County, 72 Cal. Dec. 313 (Sept. 29, 1926) the city brought a condemnation suit against various land owners to establish and maintain a reservoir to impound waters for municipal purposes. The various defendants appeared in the action and a trial was had before a jury, Judge King, of Napa County, presiding. Judgments were rendered and entered in the form of money judgments against plaintiff and allowing the condemnation. During the course of the trial an amended answer was filed by one of the defendants setting forth that the Bank of Napa held a Deed of Trust on a certain parcel of land sought to be condemned. After the entry of judgment it was discovered that the presiding judge was a stockholder of the Bank of Napa and motions were made for a new trial and to vacate and set aside the judgment, based upon the disqualification of the Judge under Sub. 1, Sec. 170 C. C. P.

In holding that the Judge was disqualified the Supreme Court states:

"The rule declared by this Court in the case of Adams v Minor 121 Cal. 372 to the effect that the Judge who is a stockholder in a bank which is a party to an action involving the validity of the bonds of an irrigation district, a portion of which is held by said bank, is an "interested" party within the meaning of Sec. 170 C. C. P. has been consistently adhered to in the later and recent decisions of this court. . . . In the face of these authorities we are constrained to hold that the interest of the respondent judge herein in these actions arising out of his relation to said bank was at all times during the pendency thereof, and still is such as to bring him within the disqualification to sit

(*Continued on Page 61*)

Digging, Cleaning Canals - *at Low Cost*



THE NEW RUTH DREDGER digs successfully in either dry or swampy ground. With its quick adjustable elevator, operating from either side of the dredger and its high speed endless chain of automatic self-emptying buckets and consequent uninterrupted flow of dirt, and ease of mobility, it operates at a minimum cost per cubic yard or lineal foot, heretofore considered impossible.

The RUTH cuts smooth even banks and bottoms—cleans canals, whether empty or filled with water, of all muck, sand, tulles, small willows and water grasses.

Write describing the type of work you contemplate doing and our engineers will gladly co-operate with you in selecting the dredger best adapted to your needs.

Send today for BULLETIN No. 9—it illustrates the NEW RUTH DREDGER, type and size of canals it digs or cleans, and gives specifications, maximum capacities, and operating costs.

IRRIGATION ENGINEERING

By ARTHUR POWELL DAVIS, D. SC.

Chief Engineer and General Manager, East Bay Municipal Utilities District; formerly President Am. Soc. C. E.; formerly Director and Chief Engineer, U. S. Reclamation Service.

AND

HERBERT M. WILSON, C. E.,

Mem. Am. Soc. C. E.; former Chief Engineer and Irrigation Engineer, U. S. Geological Survey.

Seventh Edition, Revised and Enlarged; Total Issue 12,000

THIS IS a rewritten and rearranged edition with much new material added. The principal difference introduced is the treatment of soils, plant food, operation and maintenance, and other lines of work where the duties of the irrigation engineer come in contact with the irrigator, such as in the preparation of land, the duty of water and its application to the land. A bibliography of standard works is given at the end of each chapter. 640 pages. 6 by 9. 249 figures and illustrations. Cloth, $4.50 net postpaid. Remittance must accompany the order. Allow from one to two weeks for transmittal of order and shipment from the publishers.

IRRIGATION PRACTICE *and* ENGINEERING

By B. A. ETCHEVERRY,

Professor of Irrigation Engineering, University of California.

In three volumes—the most comprehensive work in the field. A wealth of information of both practical and informative value for everyone interested in water development and conservation. Prices are net postpaid and remittances must accompany order. Allow from one to two weeks for transmittal of order and shipment from the publishers.

Vol. 1.—Uses of Irrigation Water and Irrigation Practice.....$2.50
Vol. 2.—Conveyance of Water..... 4.00
Vol. 3.—Irrigation Structures and Distribution System..... 4.50

OVERHEAD IRRIGATION

CONDUCTED BY WM. J. B. STEWART

Alfalfa Growers Look to "Overhead" for Better Irrigation

Demonstration at Chino, Calif., Shows Advantage of This System in Water and Labor Savings

The advantages of overhead irrigation on citrus groves have been so manifold that to date large installations have been almost exclusively on that type of plantings. Overhead systems will probably continue to be of more value to citrus groves than to alfalfa properties. Careful study of alfalfa irrigation by large growers and farm bureau experts, however, shows a need of better irrigation than the flooding system generally used. To quote from a recent Farm Bureau bulletin:

"Careful conservation of water, with an intelligent check-up on methods of irrigating alfalfa in Los Angeles County, is becoming increasingly important according to Assistant Farm Advisor F. H. Ernst. Excessive irrigation by the flood or surface method not only breeds trouble in some areas, causing high water tables and alkali accumulations, but contributes to direct financial losses as well. Two of the most common losses experienced by local growers are those resulting from improper field layouts where basin or checks are too large, and, the use of open ditches.

Inspection Trip Described

"At a recent tour of alfalfa growers, results of an improved surface layout were demonstrated on the T. B. Carter ranch at Lancaster, Los Angeles County, Cal. In 1925, alfalfa was irrigated in checks 30x660 feet in size. Sixty acre-inches of water were applied. By cutting the length of checks in half, the ground is now covered in nearly half the time and sufficient water supplied more economically. Due to porosity of soil and rapid penetration, practically 50 per cent of last year's water was lost through deep percolation.

"As an example of loss through open ditches, an actual measurement was made at another demonstration ranch which showed a loss of approximately 1-3 of the water during a run of 1300 feet. Twenty-one and four-tenths miner's inches were measured at the pump, of which 14½ inches remained above ground at the other end of the run. Where water is worth money, as is the case throughout Southern California, Ernst strongly urges the use of a more efficient system of distribution."

Such a system was demonstrated before a large contingent of alfalfa growers at a meeting under Farm Bureau supervision Nov. 11 at the I. B. Netzley ranch at Chino, Cal. A twenty-acre unit of alfalfa on this ranch has been equipped with overhead irrigation, pressure being supplied by a centrifugal type booster pump. As there is but a six-inch fall in the surface of this unit it was formerly very difficult to irrigate it by any method, requiring 18 days to get the water over the area. A large portion of the water was undoubtedly lost through deep percolation.

The overhead irrigation system is in three units and with three nights of operation, with practically no attendant labor, a uniformly distributed irrigation is given the alfalfa.

The system was installed recently by Albert E. Harris.

Clarence Thomas, one of the pioneers of the overhead installation business, is engaging also in the construction of reservoirs to hold the water supply for booster pumps. He has recently completed a 2,000,000-gallon reinforced concrete reservoir for the Rubio Land and Water Association at Altadena at a cost of approximately 3-4 cent per gallon of the approximate dimensions of 110x220x 12 feet deep, the site being on a gradient of 11 per cent in rather gravelly soil. The concrete was of a rich mix, 4 inches thick on the bottom, 3 inches on the sides and reinforced with 6x6 mesh. This is the third of the Association's battery of reservoirs to supply the domestic water for the district.

Fred Farrar, of Denver, Colorado, represented the Denver and Colorado Springs chambers of commerce at the Winning of the West convention in Los Angeles. While there he invited all the delegates to the convention to be present at the conference of the western states' chambers of commerce to be held in Colorado Springs early in December.

Orange County Grower Finds Natural Gas Cheapest Fuel

Overhead Irrigation Installation on La Verne Ranch Also Utilizes New Type of Sprinkler Made in East

Another overhead irrigation system operating very economically on natural gas, a fuel available rather generally through the foothill and Orange county citrus districts of Southern California, has just been completed on the 700-acre La Verne Ranch of Ralph W. Lewis. This ranch is given over to the production of grapes, grain and citrus fruits, and a second unit of overhead irrigation will soon follow the first unit of eighteen acres that has just been completed by Clarence H. Thomas of Los Angeles.

The power plant for the booster pump is a Waukesha motor that operates the No. 800 Fairbanks-Morse centrifugal pump at 86 per cent efficiency, supplying from 200 to 700 G. P. M. at 65 pounds pressure. The power cost, using natural gas, is reported to be about one-fifth that of electricity and about one-half that of gasoline, and dependable performance is obtained.

A new sprinkler, or rather one that is the result of several months of development, makes its appearance on this installation, that for the present is known as the Thomas Special, being manufactured by a large eastern manufacturer. Although the sprinkler has a coverage 140 feet in diameter, the sprinklers on the job are being set from laterals between every third row, or about 92 feet apart. The sprinkler itself, with its positive adjustments, is said to give excellent distribution and with the carefully balanced, overlapped setting of the sprinklers this installation is expected to give an ideal distribution of water.

The greatly quickened activity on small farm land in San Diego county has resulted in much overhead irrigation work being started throughout that district. The various conditions of irregular surface, porous soil, valuable water, general absence of concrete pipe systems to date, and a water suppply under pressure have combined to greatly stimulate overhead installations.

ALL CITRUS GROWERS

talk of the

Application of Economy in Irrigation

Many of them are realizing economy in operation through the use of

Internal Combustion Engines

Overhead Irrigation is rapidly coming into favor. It is being applied by a large percentage of growers in many districts on our gas distribution system.

More Power

is required to distribute to the overhead system. Therefore, the man looking for the most practical power will find real economy in the use of

Natural Gas

The experience of pioneer overhead irrigators has proven this point. It is further being borne out by the large number of plants being equipped with Natural Gas Engines for this purpose.

Our power engineers are at your service. Full information at your nearest gas office.

Southern Counties Gas Company

With the California Railroad Commission

Will Buy Water System

Thousand Oaks Water Company has been authorized by the California Railroad Commission to acquire the water system supplying water for domestic and irrigation purposes in the Thousand Oaks District of Ventura County, heretofore operated by L. M. and M. E. Culver and S. Meyers and Hellman Commercial Trust and Savings Bank, trustee, and has been authorized to issue $38,100 of common capital stock for the purpose of paying therefor. A certificate has also been granted by the Commission to Thousand Oaks Water Company to operate said properties and the following rates have been fixed for said service:

Minimum monthly charge: 5/8"x3/4" meter, $1.50; 3/4" meter, $2.00; 1" meter, $3.00; 1½" meter, $5.00; 2" meter, $7.50; 3" meter, $12.00.

Monthly meter rates: From 0 to 1,000 cubic feet per 100 cu. ft. 30c; from 1,000 to 2,000 cu. ft. per 100 cu. ft., 25c; from 3,000 to 6,000 cu. ft. per 100 cu. ft., 20c; 6,000 to 10,000 cu. ft., per 100 cu. ft., 15c; over 10,000 cu. ft., per 100 cu. ft., 12c.

Grants New Rate Schedule

The California Railroad Commission has authorized Rodeo Water Company, owned and operated by S. J. Claeyes, to establish a new schedule of rates designed to yield a reasonable return upon the investment required to comply with the Commission's recent order for the development of an additional water supply and improvement of the service as follows: 3/4 and 5/8-inch meters, $2.25 per month; 1-inch, $4.00; 1½-inch, $5.50. Quantity rates: 300 cubic feet, or less, per month, $2.25; 300 to 1000 cubic feet, 39 cents per 100 cubic feet; 1000 to 3000 cubic feet, 32 cents per 100 cubic feet; all over 3000 cubic feet, 27 cents per 100 cubic feet.

Discounts Good Will Value

In authorizing Hollydale Water Company to issue $92,800 of stock for the purpose of acquiring the water system of Mercantile Investment Company in Hollydale District between the cities of Los Angeles and Long Beach, and for improvements to the same amounting to $31,600, the California Railroad Commission refused to permit the purchasers of this system to capitalize going concern value. The order of the Commission eliminated the item of $7,159.40 representing going concern value.

Asks Authority for Loan

The Hanford Water Company, supplying water to the inhabitants of the city of Hanford, Kings County, has applied to the California Railroad Commission for authority to borrow from The First National Bank of Hanford the sum of $4,000, and to execute a promissory note for the above sum payable six months after date with interest at the rate of seven per cent per annum, and to use the said $4,000 together with $6,000 now on deposit to pay an outstanding note issued to P. McRae.

Will Buy Wells and Ditches

Finnelle Land Company has applied to the California Railroad Commission for permission to sell and El Camino Canal Company to purchase a well and certain ditches and pipe lines in the vicinity of Proberta, Tehama County; and El Camino Canal Company has also applied for permission to purchase from Pacific Land Corporation two wells and ditches and pipe lines in the El Camino Rancho tract, Tehama County.

Will Establish New Rates

The Richmond Company, Incorporated, operating a small water system in Contra Costa County, has applied to the California Railroad Commission for authority to establish a $5.00 meter deposit on all new services, and a minimum monthly charge of $1.75 for four hundred cubic feet of water, and 50 cents per 100 cubic feet for all water used in excess of 400 cubic feet.

Asks Permit for Bond Issue

Haines Canyon Water Company, engaged in the distribution of water in the city of Tujunga, Los Angeles County, has applied to the California Railroad Commission for authority to issue $25,000 of bonds, bearing interest at the rate of six and one-half per cent, for the purpose of reimbursing its treasury for expenditures made to purchase necessary equipment.

Would Sell Water System

B. H. Steffen, operating a public utility water system in the city of Chico and vicinity, Butte County, under the name of Chico Vecino Water Company, has applied to the California Railroad Commission for authority to sell said system to C. B. Jackson, who has applied for permission to take over and operate same.

Would Buy Heber Waterworks

W. A. Hensley has applied to the California Railroad Commission for permission to sell and transfer Heber Waterworks to George Dyer Thompson, and the latter has applied to take over and operate the system, which supplies water to the town of Heber, Imperial County.

Edison Co. Sells Water System

Southern California Edison Company, having sold its Mound Water System in and near the city of Ventura, the California Railroad Commission today relieved that company of any further public utility obligations to furnish water in that territory.

Will Sell Right-of-Way

Port Costa Water Company has been granted permission by the California Railroad Commission to sell 6.386 acres of land for the sum of $5,250.00 to East Bay Municipal Utility District as a right-of-way for a pipe line.

Asks Permit for Water system

Ford L. Howland has applied to the California Railroad Commission for a certificate to operate a public utility water system for irrigation purposes and domestic use in the vicinity of Santa Anita Colony, Los Angeles County.

Water Company Will Sell Land

East Bay Water Company has been authorized by the California Railroad Commission to sell to Giacomo Badano approximately 5.71 acres of land in Contra Costa County, for the sum of $2,280.

Legal and Judicial News

(*Continued from Page 56*)

or act therein defined in Sec. 170 Sub. 1 C. C. P. It follows necessarily that whatever actions, orders or judgments have been taken, made, given or entered by said Judge in said action, or either of them, during the existence of such disqualification, the same and each of them were, are and continue to be wholly void."

Change in Point of Diversion Must Not Injure Later Appropriation

Under Idaho Statutes action of Commissioner of Reclamation in granting permit for change of point of diversion is not exclusive.

In the case of Crockett vs. Jones 249 Pac. 483; June 26, 1926, the Supreme Court of Idaho held that the remedy of an appeal to the District Court provided by the State statutes from the action of the Commissioner of Reclamation, granting a permit for a change of point of diversion of waters, is not exclusive, but cumulative, he being an administrative officer without judicial power. Instead thereof the aggrieved party might bring an original action in such court for determining the question involved in the proceedings before the Commissioner.

In the case before the court it appears that the water supplied to the appropriator arose below the point to which he desired to move his point of diversion. By reason of these conditions the court stated:

"An appropriator of water may not change his point of diversion, under C. S. par. 5563 to a point higher up stream, if water supplied him arose between the two points, and such condition existed at the time of the subsequent appropriations, and the change would injure the subsequent appropriators."

Taxes Can Be Paid Only in Money.

Acceptance of checks by collector or treasurer is not payment.

A decision of interest to Irrigation District officials (such officials corresponding with county officials) is rendered by the Supreme Court of South Dakota in the case of Eggleston vs. Plowman, as Treasurer, 207 N. W. 981 (44 A. L. R. 1231). In that case the court held:

"A County Treasurer has no authority to accept anything other than money in payment of taxes unless expressly authorized to do so by statute.

"In the absence of an express agreement otherwise, payment by draft or check is conditional payment ripening into payment only when the draft or check is in fact paid.

"The rule that want of diligence in presenting for payment a draft sent in satisfaction of a claim extinguishes the liability of the drawer, cannot be applied in favor of a taxpayer sending a bank draft to the collector in payment of taxes, and therefore the negligence of the collector in failing to present the draft for payment before the insolvency of the drawer, so that the draft becomes uncollectable, does not release the taxpayer from his liability for the taxes, and Mandamus will not lie to compel issuance of tax receipts by the tax collector."

SURVEY *of* HYDRAULIC DEVELOPMENT

As Shown by Official Records of the Month -- Local, State, and Governmental

Applications Filed

Among the more important applications for permit to appropriate water filed with the California Department of Public Works, Division of Water Rights, during the month of October, 1926, were the following:

Application No. 5225 (San Bernardino County)—Walter A. Geft, 4816 6th Ave., Los Angeles, Calif. for .12 cubic foot per second from Old Sheep Corral Springs (2) tributary to Santa Ana River to be diverted in Sec. 34, T 2 N, R 2 E, S. B. M. for domestic and irrigation purposes on 25 acres in Sec. 27, T 2 N, R 2 E, S. B. M. Estimated cost $1200.

Application No. 5229 (Eldorado County)—Dr. A. L. White, Placerville, Calif., for 150 acre feet per annum from Shingle Creek tributary to S. Fk. American River to be diverted in Sec. 19, T 11 N, R 10 E, M. D. M. for irrigation purposes on 80 acres.

Application No. 5230 (Butte County)—Mrs. L. A. Kister, Rt. B, Oroville, Cal. for 2.21 cubic feet per second from Feather River tributary to Sacramento River to be diverted in Sec. 10, T 18 N, R 3 E, M. D. M. for irrigation purposes on 177 acres in Secs. 10 and 11, T 18 N, R 3 E, M. D. M. Estimated cost $10,000.

Application No. 5231 (Sacramento County)—William McLauchlin, 8 Atlantic Ave., Long Beach, Calif., 3.00 cubic feet per second from Linda Creek tributary to Sacramento River to be diverted (1) intersection of Lots 41, 43, 48 and 49 (2) on Linda Creek on line between Lots 33 and 34 both in Rio Linda Subdivision No. 1 for agricultural purposes on 100 acres alfalfa. Estimated cost $1,500.

Application No. 5232 (Plumas County)—J. N. Evans Estate Co., 539 Riverside Drive, Reno, Nevada, for 200 acre feet per annum from Taylor Lake tributary to Hungry and Indian Creeks to be diverted in Sec. 35, T 27 N, R 11 E, M. D. M. for agricultural purposes on 510 acres alfalfa and general crops. Estimated cost $1000.

Application No. 5236 (San Diego County)—Mrs. R. Silva, Box 224 Escondido, Calif., for 0.25 cubic foot per second from Los Cochis Creek tributary to San Diego River to be diverted in Sec. 13, T 15 S, R 1 E, S. B. M. for irrigation and domestic purposes in Sec. 13, T 15 S, R 1 E, S. B. M. (12 acres). Estimated cost $1500.

Application No. 5237 (Alameda County)—Henry Linderman, Sr., c/o Ohm & Raab, 517 E. Market St., Stockton, Calif., for 5.44 cubic feet per second from Kennedy Cut tributary to Old River to be diverted in Sec. 29, T 1 S, R 4 E, M. D. M., for agricultural purposes on 435.8 acres. Estimated cost $8,000.

Application No. 5239 (Lake County)—William A. Forbes, 750 12th Ave., San Francisco, Calif., for 0.56 cubic foot per second from Seigler Creek tributary to Cache Creek to be diverted in Sec. 19, T 12 N, R 7 W, M. D. M., for irrigation and stock watering purposes on 120 acres. Estimated cost $1500.00.

Application No. 5241 (Lake County)—James P. Smith, Kelseyville, Calif., Box 262, for 1.0 cubic foot per second from Cold Creek to be diverted in Sec. 36, T 13 N, R 9 W, M. D. M. for irrigation and domestic purposes on 80 acres.

Application No. 5243 (Mariposa County)—Louise Land Co., La Grande, Calif., for 60,000 acre feet per annum from Chowchilla River tributary to San Joaquin River to be diverted in Sec. 18, T 7 S, R 20 E, M. D. B. & M., for irrigation of 20,000 acres. Estimated cost $400,000.

Application No. 5244 (Sutter County)—D. C. Smith et al, Meridian, Calif., for .150 cubic feet per second from Butte Creek tributary to Sacramento River to be diverted in Sec. 36, T 16 N, R 1 W, M. D. M. for stock watering purposes and irrigation of 8000 acres.

Application No. 5245 (Placer County)—Bank of Italy as Trustee for A. K. Detwiler and Wm. J. D. Lambert, Tahoe City, Calif., for 1 cubic foot per second from unnamed spring tributary to Lake Tahoe to be diverted in Sec. 22, T 15 N, R 16 E, M. D. M., for agricultural and domestic purposes on 80 acres in Sec. 13.

Application No. 5247 (Tuolumne County)—Sierra and San Francisco Power Co., San Francisco, Calif., for 60,000 acre feet per annum from Middle Fork Stanislaus River tributary to San Joaquin River to be diverted in Sec. 11, T 1 N, R 13 E, M. D. M. for irrigation and domestic purposes on 150,000 acres.

Application No. 5248 (San Joaquin County)—Banta-Carbona Irrigation Dist., Tracy, Calif., for 40 cubic feet per second from San Joaquin River tributary to San Francisco Bay to be diverted in Rancho El Pescadero for agricultural and domestic purposes on 18.486 acres. Estimated cost $334,000.

Permits Issued

Among the more important permits to appropriate water issued by the Department of Public Works, Division of Water Rights, California, during the month of October, 1926, were the following:

Permit No. 2635, Application No. 5023 (Inyo County) Issued to Reorganized Silver King Divide Mining Co., Reno, Nevada, October 5, 1926, for 0.03 cubic foot per second from 2 springs in Sec. 1, T 24 S, R 42 E, for mining, milling and domestic purposes in Secs. 35 and 36, T 23 S, R 43 E. Estimated cost $3,500.

Permit No. 2640, Application No. 4995 (Ventura County) Issued to James Erwin, Piru, Calif., October 9, 1926, for .1 cubic foot per second from unnamed creek and spring in Sec. 10, T 4 N, R 19 W, for domestic and irrigation of 7 acres in Sec. 10.

Permit No. 2641, Application No. 5033 (Los Angeles County) Issued to Sara Hedge Stevens, Llano, Calif., October 11, 1926, for 0.075 cubic foot per second from a spring in Sec. 25, T 4 N, R 8 W, for domestic, stock and irrigation of 8 acres in Sec. 25. Estimated cost $1000.

Permit No. 2643, Application No. 5082 (Mendocino County) Issued to Wilfred Bradbreek, Spyreck, Calif., October 13, 1926, for .22 cubic foot per second from Burns Creek in Sec. 36, T 24 N, R 15 W, for irrigation of 20 acres in Sec. 30, T 24 N, R 14 W.

Permit No. 2645, Application No. 5120 (San Joaquin County) Issued to Jack Klein and Sol D. Klein, Stockton, Calif., October 14, 1926, for 4.19 cubic feet per second from Middle River in Sec. 1, T 1 S, R 4 E, for irrigation of 335.4 acres near point of diversion. Estimated cost $3,500.

Permit No. 2646, Application No. 5121 (San Joaquin County) Issued to M. G. Oliveira, Stockton, Calif., October 15, 1926, for 4.7 cubic feet per second from Burnes Cutoff in Sec. 12, T 1 N, R 5 E, for irrigation of 377.6 acres near point of diversion. Estimated cost $6000.

Permit No. 2647, Application No. 5153 (San Joaquin County) Issued to Theodore Lorenzen, Stockton, Calif., October 15, 1926, for 12.34 cubic feet per second from San Joaquin River in Sec. 22, T 2 S, R 6 E, for irrigation of 987.6 acres near point of diversion. Estimated cost $16,000.

Permit No. 2649, Application No. 5160 (Sutter County) Issued to The Commercial Investment Co., Sacramento, Calif., October 18, 1926, for 1.75 cubic feet per second from Sacramento River in Sec. 11, T 11 N, R 2 E, for irrigation of 140.07 acres near point of diversion. Estimated cost $3000.

Permit No. 2651, Application No. 4956 (Butte County) Issued to Mrs. Kate Haack, Oroville, Calif., October 21, 1926, for 3 cubic feet per second from Lateral E-I of Recl. Dist No. 833 Drainage Ditch in Sec. 6, T 17 N, R 2 E, for irrigation of 128 acres of rice in Sec. 6.

Permit No. 2653, Application No. 4904 (Santa Barbara County) Issued to Caleb A. Ensign, Maricopa, Calif., October 22, 1926, for 0.37 cubic foot per second from Eckert Canyon Creek in Sec. 12, T 10 N, R 29 W, for domestic and irrigation of 45 acres in Sec. 7.

Permit No. 2654, Application No. 4104 (San Mateo County) Issued to Islam Redwoods Shrine, San Francisco, Calif., October 22, 1926, for 4.59 cubic feet per second not to exceed 3 cubic feet per second from any one source, from Evans, Slate and Peters Creeks in Secs. 3 and 5, T 8 S, R 3 W, for domestic use and irrigation of 1640 acres near point of diversion. Estimated cost $51,100.

Permit No. 2655, Application No. 5136 (Del Monte County) Issued to C. F. Huffman, Crescent City, Calif., October 25, 1926, for 0.27 cubic foot per second from an unnamed spring in Sec. 35, T 16 N, R 1 W, for domestic and irrigation of 22 acres in Sec. 26.

Permit No. 2657, Application No. 5054 (San Diego County) Issued to C. M. Eichenlaub, San Diego, Calif., October 26, 1926, for 0.12 cubic foot per second from Skye Valley Creek in Sec. 2, T 17 S, R 3 E, for domestic, stock and irrigation of 10 acres near point of diversion. Estimated cost $400.

Permit No. 2658, Application No. 5092 (San Joaquin County) Issued to Edna Gianelli, et al, Stockton, Calif., October 26, 1926, for 15.15 cubic feet per second from Beaver Slough and S. Fork Mokelumne River in Secs. 17 and 18, T 4 N, R 5 E, and Sec. 12, T 4 N, R 4 E, for irrigation of 1212.1 acres near point of diversion. Estimated cost $15,000.

Permit No. 2660, Application No. 4896 (Sacramento County) Issued to E. O. Morse, Elk Grove, Calif., October 30, 1926, for 11.5 cubic feet per second from Burton Slough and Mokelumne River in Secs. 16, 17, 20, 21 and 28, T 5 N, R 5 E, for irrigation of 920.2 acres near point of diversion. Estimated cost $5000.

OREGON

Among the more important applications for permit to appropriate water filed in the office of Rhea Luper, State Engineer of Oregon, from October 9 to November 13, were the following:

F. M. Lockwood of Walla Walla, Washington, covering the appropriation of water from East Br. Mud Creek and Swamp drainage, tributary of Walla Walla River, for mostly winter irrigation and washing out alkali of 35 acres in Umatilla County.

City of Newport, a municipal corporation, of Newport, Oregon, covering the appropriation of water from Big Creek and its tributaries, for Municipal Water Supply, in Lincoln County.

J. G. Jarvis, of Hood River, Oregon, covering the appropriation of water from Seepage water and waste water to Whiskey Creek, tributary of Hood River, for the irrigation of 10 acres in Hood River County.

James Trimble of Hereford, Oregon, covering the appropriation of water from Burnt River, tributary of Snake River, for irrigation of 37 acres in Baker County.

Minette Sentner of Cove, Oregon, covering the appropriation of water from Springs and Swamps, tributary of Mill Creek, for irrigation of 20 acres in Union County.

J. B. Curl, of Port Orford, Oregon, covering the appropriation of water from Bald Mountain Creek, tributary of Elk River, for municipal supply for City of Port Orford, in Curry County, Oregon.

Frank Cook of Turner, Oregon, R. F. D. No. 2, covering the appropriation of water from Cook Creek, tributary of Mill Creek, for irrigation and power, irrigation of 20 acres in Marion County.

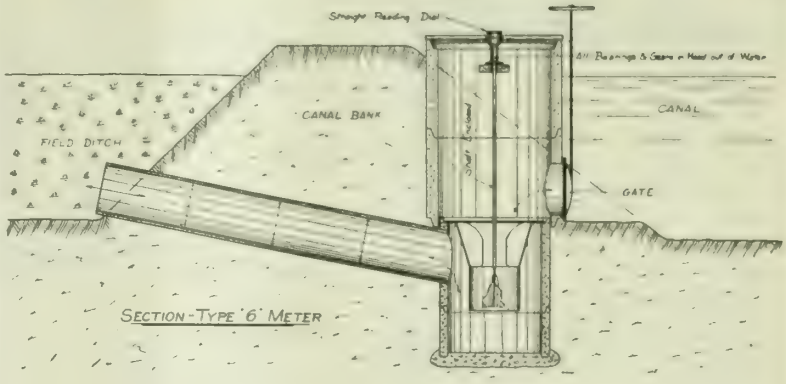
G. H. Lund and Dena Towle, of Cove, Oregon, covering the appropriation of water from waste water raised on the NW ¼ of Sec. 15, T. 3 S, R. 40 E, for the irrigation of twenty acres in Union County.

C. A. Lockwood of Roseburg, Oregon, covering the appropriation of water from North Umpqua River, tributary of Umpqua River, for irrigation of 12 acres in Douglas County.

Earl Bechdolt of Butte Falls, Oregon, covering the appropriation of water from Beaver Dam or Parsnip Creek, tributary of Buck Creek (Middle Fk. Rogue River) for irrigation of 100 acres in Jackson County.

William S. Woodcock of Malheur, Oregon, covering the appropriation of water from Cottonwood Gulch and springs, tributary of

The RELIANCE METER



THE "Type 6" Reliance Irrigation Meter offers you standardized permanent construction at a very low first cost. Their sustained efficiency with a minimum of upkeep has been proven by 12 years usage. Cut shows installation of the 4 sec. ft. size in 24 and 30-inch concrete pipe. This is the standard type of setting adopted by many irrigation districts in Texas and elsewhere who are now equipping all their deliveries with this device. The "Type 6" meter is furnished in sizes ranging from ½ up to 16 sec. ft.

Willow Creek, for the irrigation of 10 acres in Malheur County.

R. E. Scott of Mitchell, Oregon, covering the appropriation of water from Gable Creek, tributary of Bridge Creek for supplemental irrigation of 98.4 acres during the non-irrigation season in Wheeler County.

The Roseburg Country Club of Roseburg, Oregon, covering the appropriation of water from North Umpqua River, tributary of Umpqua River, for domestic purposes and the irrigation of 104 acres in Douglas County.

Samuel E. Perkins, of Kerby, Oregon, covering the appropriation of water from Mendenhall Creek, tributary of West Fork Illinois River, for the irrigation of 15 acres in Josephine County.

H. F. McCormick, of St. Helens, Oregon, covering the appropriation of water from Milton Creek, tributary of Columbia River, for the irrigation of 72 acres in Columbia County.

Albert Johnson, of Canyon City, Oregon, covering the appropriation of water from Canyon Creek, tributary of John Days River, for the irrigation of 12 acres in Grant County.

Nick Barry, of Adel, Oregon, covering the appropriation of water from a reservoir on Jack Creek, tributary of Guano Lake, for the irrigation of 640 acres in Lake County.

U. S. Reclamation Report Cites New Confidence of Settlers

Adjustment Act Held Responsible for New Spirit of Optimism on Federal Projects; Construction Progress Given

Enactment of the Reclamation Adjustment Act has resulted in a spirit of confidence, optimism, and cooperation among settlers on Federal reclamation projects, according to the annual report of the Commissioner of Reclamation to the Secretary of the Interior.

Summarizing its beneficial effect the report points out that the reclamation projects have been more nearly placed on a strictly business basis than at any time in their history, the threat of having to pay water charges on unproductive land has been taken from settlers, debts which water users did not believe they should be called upon to pay have been wiped out, and time of payment has been extended so that the adverse influence of temporary hard times in agriculture has been overcome.

Boost in Crop Values

The Commissioner's report shows that the total value of crops grown in 1925 on irrigated lands furnished in whole or in part from Government irrigation works was $131,000,000, compared with $110,000,000 in 1924, an increase of $21,000,000. Total payments from water users to the Reclamation Bureau increased from $3,811,600 in 1924 to $4,454,800 during the fiscal year of 1925, a gain of $643,200.

Regarding the engineering activities of the Bureau, the report announced that the Gerber dam on the Klamath project in Oregon-California, and the McKay dam for the irrigation of the greater Umatilla project in Oregon will be completed this year. Construction of the Guernsey dam on the North Platte project in Nebraska-Wyoming was continued during the year and plans were made for the construction of the Stony Gorge dam on the Orland project in California and the Gibson dam on the Sun River project. Contracts for the first unit of the Kittitas division of the Yakima project in Washington have been finished while plans are being consummated for the early commencement of construction of the Vale and Owyhee projects in Oregon. In the absence of convincing evidence of the feasibility of the Baker project in Oregon, nothing has been done toward carrying it out.

Wage Settlement Campaigns

The report announced that an intensive settlement campaign had been made on the Belle Fourche project in South Dakota and the Lower Yellowstone project in Montana-North Dakota. Both of these projects need settlers who will be good farmers. If a considerable acreage of the unoccupied or unirrigated lands on these projects can be settled with the right type of farmers by the beginning of the next irrigation season, it will have placed two Federal reclamation projects on a sound financial footing and pointed the way to similar development on other projects.

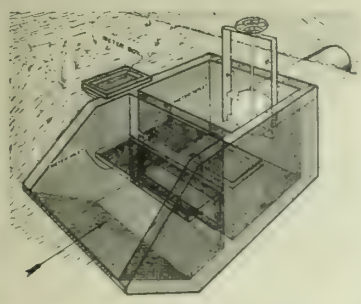
Under an appropriation of $15,000, plans were being made for a preliminary survey of opportunities in the southern States for planned rural community development, a report on which will be made to Congress at the coming session.

Bureau of Reclamation to Test Imperial's Levees in Mexico

Imperial Irrigation District Makes Request Following Query by California Bankers Association

The Federal Bureau of Reclamation has been invited by the Imperial Irrigation District of California to make a survey of the protective levees below the Bee River Dam in the republic of Mexico, the Interior Department announced on Oct. 26.

The invitation was sent to Dr. Elwood Mead, Commissioner of the Reclamation Bureau, in the form of a resolution adopted by the Imperial Valley irrigation organization after the California Bankers Association expressed doubt over whether the levees were of the proper height to avert floods along this river. The district promises to furnish the Reclamation Bureau the necessary



Submerged Orifice Measuring Structure

acre foot meter and turn out gate combined.

large measure, to A. P. Lovell, superintendent of the San Diego water department, who was chairman of the committee on arrangements. Mr. Lovell's committee also gave generous assistance to the exhibitors. Fifty exhibitors in all occupied booths in the convention hall and their displays comprised a complete line of equipment and supplies necessary to the construction and operation of a modern waterworks system.

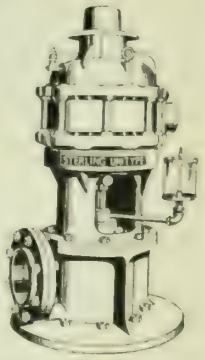
The election of officers resulted in the choice of S. B. Morris for the chairmanship of the section. Mr. Morris is chief engineer of the Pasadena water department and served as vice chairman of the Section during the past year, and as secretary-treasurer prior to that.

J. J. Ryland of San Jose was elected vice chairman, and Paul Magerstadt of the East Bay Water Company, Oakland, was re-elected secretary. P. Dietrich and John Burt will compose the executive committee for the coming year.

Next year's convention will be held at San Jose, the exact dates to be announced later.

Sterling Quality CENTRIFUGAL PUMPS

VERTICAL PUMPS for Surface or Pit Pumping. Same construction features as the split case Centrifugal Pump. Sizes—1½ in., 2 in., 3 in., 4 in., 5 in., 6 in., & 8 in. Send for bulletin No. 21.



Sterling Unitype Drive
The Original

Deep Well Turbine Pumps

Made for the following well diams.: 4 in., 6 in., 7 in., 8 in., 10 in., 12 in., 14 in., 16 in., 18 in. and 20 in. Capacities 20 G.P.M. to 4,000 G.P.M. Send for Bulletin No. 16.

NOTE—The motor drive for this vertical pump interchanges with the deep well Turbine Drive.

contractor must have idle men on his hands the balance of the day, as it is not practical to hire men for half a day. Next, there is the continuous wetting, either by puddling or covering the whole surface with wet earth. Then there is the question as to whether the shoveling onto the pavement of earth and small rocks does any damage to the surface of the pavement.

"It is impractical for the contractor to clean off a piece of pavement as soon as the curing period is over, so as a rule this earth is left upon the pavement until completion of the project or until a great portion is completed; then it is bladed into wind-rows. The blade, in scraping over the top of the pavement, may damage the newly set crystals, causing the pavement to "dust" on top.

"The wind-rowed earth may either be loaded by machine or hand in trucks, and hauled away to a dumping ground. Then the pavement is thoroughly cleaned and a color coat is applied for the purpose of killing the glare of a white pavement. Frequently before this curing earth is removed it becomes dry, and if traffic is allowed on it, dust blows into homes, upon lawns, shrubbery and so on."

Editorial Jottings About Current and Forthcoming Feature Articles, Dealing With Practical Problems of Hydraulics, and the Men Who Have Written Them

GEORGE S. HENRY, whose contribution in this issue describes the plan developed by the Vista Irrigation District, in southern California, for a satisfactory settlement of its riddle of water allocation, is a man who brings to the important office of president of an irrigation district a specialized training and experience not generally found in such high

GEORGE S. HENRY

places. Mr. Henry is a graduate of Harvard, where he specialized in hydraulics and irrigation engineering. His early experience was gained in engineering work in Mexico, and he was later associated with his father, the late T. C. Henry, of Denver, in irrigation development in Colorado, Utah, New Mexico and other sections of the Southwest. In 1911 he removed from Colorado to California, where he has been engaged since that time in irrigation and land development and settlement. When the Vista Irrigation District was formed, his wide experience in irrigation district law and practice as well as his knowledge of the technical and financial problems incidental to the successful launching of such a project, fitted him admirably for the post to which he was chosen—that of the district's first president.

FOR MORE than a generation William Mulholland, who describes the proposed Colorado aqueduct, has been a notable figure in waterworks and engineering circles of Southern California. During the forty years that he has been superintendent and chief engineer of the Los Angeles water system he has played an active part in the development of many irrigation and water supply projects. The Owens River aqueduct is perhaps his best known piece of work. For this project he devised the plans and superintended the construction of an aqueduct for conveying a supplementary water supply from the Sierra Nevada Mountains to Los Angeles, a distance of 250 miles, at a cost of $24,500,000. Mr. Mulholland was born in Belfast, Ireland, in 1855. He received his education in Dublin, and was awarded the degree of LL.D. by the University of California.

THE ARTICLE telling of the work in irrigation done by the Washington State College is one of a series in which is being related the significant story of the contributions which the higher institutions of learning in all parts of the West are making to the progress of irrigation knowledge—and, more important, to the application of that knowledge. O. L. Waller, author of the article, is well qualified to summarize the relationship between his college and irrigation in the Northwest. In addition to being vice-president of the institution, and head of its department of civil engineering, he has himself had an important part in the irrigation history of Washington. In 1900, he was appointed expert in irrigation drainage for the United States Department of Agriculture; in 1915, he was chairman of the federal Board of Review named to report to the Secretary of the Interior the condition of federal irrigation projects in the state; he was chairman of the Water Code Commission, appointed by the governor to revise the state's water laws; he was a member of the Columbia Basin Commission, named by the legislature to study the possibility of developing the Columbia plateau through irrigation; and he recently served as a member of the federal board of engineers created to report to the Secretary of the Interior on the feasibility of the Columbia Basin Irrigation project.

DR. CARL WILSON, who writes the article on the Biological Control of Reservoirs, is director of the biological laboratory of the Los Angeles Bureau of Waterworks and Supply. Dr. Wilson

DR. CARL WILSON

has "followed the game" for twenty-five years and for half of that time has been in his present position. Before becoming a member of the Los Angeles Water Department he spent three years with a private waterworks company in Monterey, Mexico, and for a number of years was engaged in private practice.

CHARLES H. LEE is not unfamiliar to readers of MODERN IRRIGATION. He is the author of the "Water Survey of San Francisco District," published in our October issue. Mr. Lee is a consulting engineer in private practice in San Francisco, and specializes in water supply and development. The plan he proposes in this issue for determining the future water requirements of metropolitan areas will be discussed further next month.

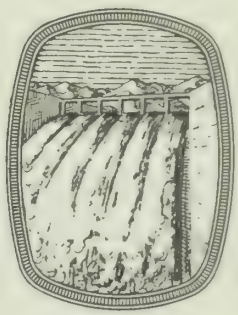
MAJOR C. R. OLBERG

Who, in his capacity of engineer in the U. S. Indian Service, designed the Coolidge Multiple Dome Dam on the San Carlos, Arizona, irrigation project. Major Olberg has to his credit not only the accomplishment of the preliminary work, including the design, of the Coolidge Dam, but also the construction of the Ashurst-Hayden Dam, the design and part of the construction of the Sacaton Dam and Bridge, both in Arizona, and is in charge of the San Carlos project in that state. He has been in the Indian Service for 26 years.

MODERN Irrigation
The Magazine of Applied Hydraulics



Volume II DECEMBER, 1926 Number 12

The Progress *of* Irrigation

A TENTATIVE ten-year construction program for Federal reclamation with total estimated expenditures amounting to $97,514,000 that will result in the completion of all existing Government projects, has been proposed by the Interior Department.

The program contemplates construction work on 22 unfinished projects in 17 Western States with annual expenditures averaging between $8,446,000 and $10,826,000, a sum exceeding the probable average annual income of the Reclamation Fund by about $1,000,000. If adopted, the program will preclude the undertaking of any new projects by the Government during this period.

Annual construction work to carry out the proposed program provides for the expenditure of $10,826,000 in 1928; $10,239,000 in 1929; $9,118,000 in 1930; $9,180,000 in 1931; $8,597,000 in 1932; $8,450,000 in 1933; $8,521,000 in 1934; $8,730,000 in 1935; $8,584,000 in 1936; $8,446,000 in 1937 with an additional $6,823,000 to be expended thereafter. An outline of the apportionment by projects of these annual expenditures under the program follows:

A total of $1,291,000 has been apportioned to complete the distribution, drainage and power systems of the Yuma, Arizona-California project. Of this amount it is proposed to expend $35,000 in 1928, $60,000 in 1929, $55,000 in 1930, $550,000 in 1931 and $591,000 in 1932. This project under the program will be completed in 1932.

A total of $727,000 will be used to construct the Stony Gorge reservoir and complete lateral canal extensions and linings on the Orland, California, project, the proposed expenditures consisting of $605,000 in 1928, $32,000 in 1929, $30,000 in 1930, $30,000 in 1931, and $30,000 in 1932. This project under the program will be completed in 1932.

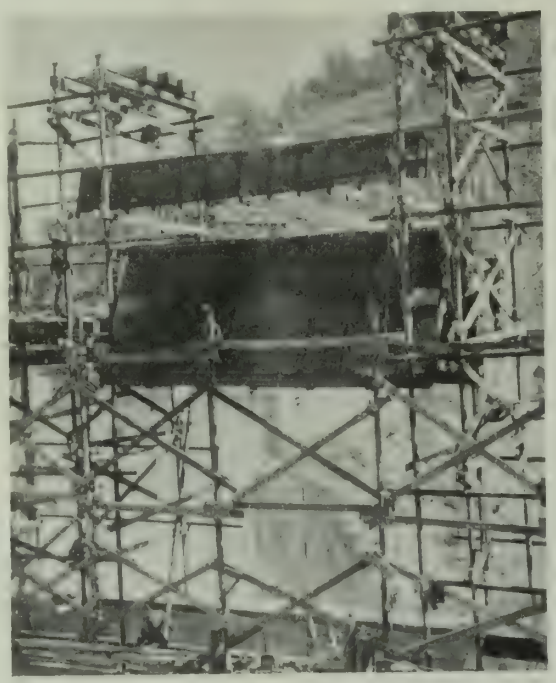
The sum of $136,000 has been apportioned to complete distribution and drainage systems of the Grand Valley, Colorado, project, divided as follows: $30,000 in 1928, $30,000 in 1929, $30,000 in 1930, $30,000 in 1931, and $16,000 in 1932. This project under the program will be completed in 1932.

An aggregate of $500,000 for drainage system on the Uncompahgre, Colorado, project has been proposed, $300,000 to be expended in 1932 and $200,000 in 1933. Under the program this project will be completed in 1933.

"Western Waterworks" Begins on Page 25

A total of $6,334,000 will be spent for main canal betterments, and drainage on the Arrowrock and Payette divisions of the Boise, Idaho, project, distributed as follows: $116,000 in 1928, $84,000 in 1929, $50,000 in 1930, $1,000,000 in 1932, $1,500,000 in 1933, $1,500,000 in 1934, $1,500,000 in 1935, and $584,000 in 1936. This project under the program will be completed in 1936.

A total of $8,423,000 has been apportioned to complete American Falls reservoir, American Falls power development, Minidoka power development, south side pumping division drainage and north side pumping unit at Minidoka, Idaho. This proposed expenditure is divided as follows: $1,583,000 in 1928, $1,000,000 in 1930, $2,671,000 in 1931, $1,000,000 in 1932, $1,250,000 in 1933, and $919,000 in 1934. This project under the program will be completed in 1934.



Lowering drumgate A-2, Melones Dam, Oakdale and South San Joaquin Irrigation Districts, California.

A total of $181,000 will be spent to complete the St. Mary Canal and Sherburne Lakes reservoirs and canal and lateral system at Milk River, Montana, with $17,000 expended in 1928, $40,000 in 1929, $40,000 in 1930, $49,000 in 1931, and $35,000 in 1932. Under the program this project will be completed in 1932.

The sum of $3,653,000 will be used for Gibson reservoir, Fort Shaw distribution system, north side distribution system and north side drainage at Sun River, Mont., with $1,037,000 expended in 1928, $1,165,000 in 1929, $500,000 in 1935, $500,000 in 1936 and $451,000 in 1937. This project under the program will be completed in 1937.

On the Lower Yellowstone, Montana-North Dakota, $460,000 has been apportioned to complete drainage system divided as follows: $100,000 in 1928, $180,000 in 1929, $180,000 in 1930. This project under the program will be completed in 1930.

A total of $707,000 will be set aside to complete Guernsey reservoir, power development, distribution and drainage systems on the Interstate and Fort Laramie division of the North Platte, Nebraska-Wyoming project, the expenditures to be divided as follows: $450,000 in 1928, $147,000 in 1929, $75,000 in 1930, and $35,000 in 1931. Under the program this project will be completed in 1931.

At Newlands, Nevada, $1,164,000 will be spent for Truckee storage, canal construction, a power system and Carson division distributing system of which $64,000 is to be expended in 1928, $50,000 in 1929, $50,000 in 1930, $500,000 in 1934 and $500,000 in 1935. This project under the program will be completed in 1935.

At Carlsbad, New Mexico, $1,001,000 has been voted for McMillan reservoir claims and for Avalon water storage divided as follows: $501,000 in 1929 and $500,000 in 1930, thus completing this project in that year.

A total of $590,000 has been apportioned to complete the distribution and drainage system of the Rio Grande, New Mexico-Texas project divided as follows: $400,000 in 1928 and $190,000 in 1929. This project under the program will be completed in 1929.

At Owyhee, Oregon, $17,714,000 will be spent to construct storage, canal, and drainage systems as follows: $2,000,000 in 1928, $3,000,000 in 1929, $3,000,000 in 1930, $3,000,000 in 1931, $3,000,000 in 1932, $3,000,000 in 1933, and $714,000 in 1934, thus completing the project in 1934.

A total of $3,115,000 for storage, canal, drainage, and distribution system on the Vale, Oregon, project, will be divided as follows: $750,000 in 1928, $750,000 in 1929, $750,000 in 1930, and $865,000 in 1931. This project under the program will be completed in 1931.

The Klamath, Oregon-California, project will receive $1,831,000 to complete Tule Lake distributing and drainage systems, Langell Valley (Clear Lake) and Langell Valley (Gerber division). Expenditure of this sum is divided as follows: $124,000 in 1928, $500,000 in 1932, $500,000 in 1933, $477,000 in 1934, and

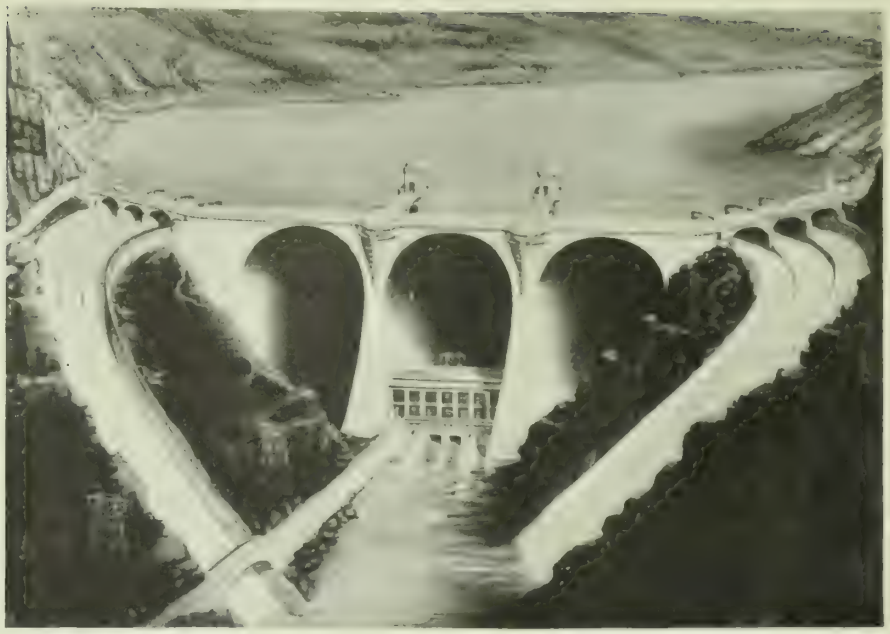
"Western Waterworks" Begins on Page 25



How the Coolidge Dam will look when completed. Contract for the construction of the dam, the first multiple dome type in the world, has been awarded to the Atkinson-Spicer Company, Los Angeles.

Engineering Aspects of Coolidge Dam Excite Interest of Hydraulic World

Multiple Dome Structure of San Carlos Project of Arizona Will be First of Its Kind in World

THE engineering world has taken great interest in the new government reclamation project, the Coolidge Dam, the contract for which has just been given to the Atkinson-Spicer Company of Los Angeles. The dam was designed by Major C. R. Olberg, engineer on the United States Indian Service, and is known as the Multiple-Dome Type. It will be the first of its kind ever built.

Major C. R. Olberg is a well known hydraulic engineer, and has been in the government service since his graduation from George Washington University in 1900. He was in charge of the preliminary work, including design of the Roosevelt Dam; constructed the Ashurst-Hayden Dam in Arizona; was in charge of the design and part of the construction of the Sacaton Dam and Bridge in Arizona; and is now responsible for the development of this new work, the San Carlos Project of Arizona.

Local History

Colonel J. H. McClintock, former state historian of Arizona, has given some interesting information in regard to the former occupants of the San Carlos area, and in a recent article stated:

"The area to be reclaimed, named after the ruins of the prehistoric community houses, was farmed, a thousand years ago, by a people who built canals from the Gila and who were possessed of a culture similar to that of the Pueblo tribes of today. Their homes were ruins when seen, about 1694, by Padre Kino, the first white man to write of the region, while the Pimas tell that when their forefathers came the ruins were even then ruins. The Pimas cleaned out some of the ancient ditches and were farming when the Spaniards arrived, raising corn, cotton, beans, and squash. Being land owners, they were conservative among the Indians and they joyously helped the white man in his campaign against the Apache Ishmaelites of the hills.

"About 1870, the white man began diversion of water around Florence, and a few years later more waters of the Gila were taken out around Safford, farther up the stream. The minimum flow of the stream thus became appropriated, to the injury of the Indians, though it is known that their summer supply had always been limited and often non-existent. Year after year attempts were made to secure appropriations for the benefit of the Pimas, whose story of friendship for the whites has had frequent repetition."

The plan of giving assistance to the Pima Indians has been contemplated by the Indian Office for a great many years, but conditions prevented the materialization. It was for this reason that Edgar B. Merritt, assistant commissioner of Indian Affairs, was instrumental in preventing the granting of permit to a large transcontinental railroad to build within the area to be used by the flood waters, because he could foresee that if the railroad once established its route, it would be very expensive to have them make a change.

The dam, designated the Coolidge Dam by Congress in honor of the President, will impound water for the irrigation of some 100,000 acres of land, constituting the San Carlos Irrigation Project, in Southern Arizona. This project is being constructed under the direction of the U. S. Indian Irrigation Service, since the irrigable land is equally divided between the Pima Indians of the Gila River Indian Reservation and the white owners of lands adjacent to the towns of Florence and Casa Grande, Pinal County, Arizona. As indicated on the accompanying map, the project lands are located immediately south of the Salt River project, one of the most prosperous of those constructed by the U. S. Reclamation Bureau, and since the climatic and other physical conditions are practically the same, it is anticipated that the San Carlos project should enjoy a similar success.

The Dam Site

The site of the Coolidge Dam is located about 100 miles above lands to be irrigated, at the entrance to the Box Canyon of the Gila River, some 35 miles southeast of Globe, Arizona. San Carlos, from which the project derives its name, is located on the Southern Pacific Railroad at the confluence of the Gila and San Carlos Rivers about nine miles above the dam site.

The discharge of the Gila at the dam site varies from a few second feet during the dry season to about 92,000 second feet during maximum flood, the mean annual run off being about 400,000 acre feet. A study of the river discharge records for the past 35 years indicates that a dam rising 220 feet above the river bed, provided with floating spillway gates, was best adapted to local

"Western Waterworks" Begins on Page 25

conditions. The resulting reservoir, having an approximate capacity of about 1,200,000 acre feet, will form a lake extending up the valleys of the Gila and San Carlos Rivers a distance of about 25 miles, with a maximum width of about 2 miles. The great size of the storage reservoir and the comparatively large ratio of the storage volume to mean annual run off combine in rendering the accumulation of silt relatively unimportant, thereby relegating the silt problem to the distant future, and practically assuring an annual draft of 320,000 acre feet of water over a very long period.

The elevation of the river bed at the dam site is 2,313, U. S. G. S. datum, while the width of the canyon at the same point is about 300 feet, widening to about 600 feet at the crest of the dam. Borings at the dam site indicate that the maximum depth to bed rock is 23 feet, and it is assumed that it will be necessary to excavate ten feet into this rock to secure adequate foundations. The borings and exposed rock on the canyon sides indicate that the bed rock is hard quartzite. Suitable sand, gravel and rock are available at the site for the construction of the dam.

Developments of Multiple Dome

The building of the Coolidge dam required the removal of some 14 miles of railroad from the reservoir basin, involving some very heavy construction, and since the amount available for the dam including all charges was limited by Congress to $5,500,000, it was necessary to exercise the greatest economy to stay within the amount authorized.

Several types of dams were investigated for the Coolidge site, to determine the most economic type, and in the effort to overcome objections inherent respectively in the variable radius and multiple arch dams, the multiple dome type was developed.

This type consists of a series of egg-shaped domes supported by intermediate buttresses and the canyon walls. The development of this type was due to the apparent discovery during the course of the analytical investigation that the desirable relation respecting minimum stresses and economy of material, and the rise and span of the arch elements resisting the water pressure, formed an egg-shaped dome, the smaller end resting on the foundation and the larger forming part of the crest of the dam.

Resembles Multiple Arch Type

Superficially the dam resembles the multiple arch type since there is no distinct line of demarcation along the spring line of the arch elements forming the dome, which lends to the front elevation of the dam the appearance of a series of barreled arches. Actually very little similarity exists between the two types except that both are inclined upstream to take advantage of the water pressure and both employ buttresses in the design. Due to the egg shape of the dome, the span of the arch elements diminishes as the depth of the arch below the water surface increases, and the rear of the buttresses is flared out to support the arches. For this reason the span of the arch at the base of the dam is comparatively short and greater stability is given to the buttress.

On account of the arch and wedge action at the base due to the shape, cantilever action is virtually eliminated. At the crest, the dome shape is adapted to the use of the dam as a bridge or roadway. Each dome is supported on a continuous surface extending along the buttress or canyon walls and the foundation.

Extrados Is Surface of Revolution

The extrados, or outer surface of the dome, is a surface of revolution, since it can be generated by revolving the trace of the extrados on a vertical plane through the center of the dome and normal to the dam, around a certain inclined axis through an arc varying from 180° at the base to about 80° at the crest. Hence the trace of the extrados on the plane normal to the inclined axis is the arc of a circle with a central angle varying from 80° to 180°. The inner surface or intrados of the dome cannot be generaated in this manner owing to the necessity of increasing the thickness of the arch elements at the haunches in order to satisfy stress requirements and for this reason the trace of the intrados on the plane normal to the inclined axis is a three-centered arch. In each dome the upper section at the crest and the intrados at the heel are parts of true spherical domes.

While the dome shape undoubtedly contributes to the strength and stability of a structure, on account of the limitations of the methods of analysis available each dome is figured as a series of inclined arch elements and the beneficial effect of the dome action is not included in the calculations.

Hools' Method of Arch Analysis based on the elastic theory was used in the design since it appeared after investigation to be more rigid analytically and better adapted to the particular type and loading of the arches than other methods.

The arches are designed to have little or no tension in the concrete and to keep the compressive stresses within reasonable limits, including the effect of rib shortening and an appropriate temperature variation.

The desired stress conditions were secured by an appropriate relation of the rise of the arch to the span, by increasing the thickness of the arches as the depth increased and by increasing the thickness of the arches at the haunches. All the domes forming the dam are symmetrical, hence the transverse stresses due to arch action are balanced and carried to the canyon walls.

The buttress stresses are calculated by the monolithic method considering the domes and buttresses acting together. They were also analyzed by a modification of Cain's method as worked out by F. A. Noetzli whereby the directions and intensity of the principal stresses were determined.

Maximum Height 250 Feet

In the design of the multiple dome dam for the Coolidge site three domes and two intermediate buttresses were employed. The maximum height of the dam is 250 feet and it rises 220 feet above the stream bed. The length of the dam or canyon width at the base is about 300 feet while the distance along the crest is 580 feet exclusive of spillways. The spillways are each 150 feet in width. The distance from the rear of the dome along the base of the dam to the toe of the buttress is 286 feet. The buttresses are spaced 180 feet on centers and on the downstream side vary from 60 feet in thickness at the base to 24 feet at the narrowest section which occurs immediately below the spring of the arches forming the bridge. Their thickness at the rear at the base of the dam where they merge into the domes is 110 feet. The clear span of the arch elements forming the dome varies from 70 feet at the heel to a maximum of 150 feet at the "shoulder" of the dome while the thickness of the arches at the crown varies from four feet at the crest to 21 feet at the river bed.

The maximum compressive stress in the arches is 586 pounds per square inch including stresses due to rib shortening and to a temperature variation of 70 degrees F. at the crest, diminishing to 30 degrees F. at the base, and in the buttresses the compressive stress is about 400 pounds per square inch. The compressive stream due to the load alone in the arches is 375 pounds per square inch and with load and rib shortening excluding temperature, 500 pounds. The stress based on the cylinder formula is 370 pounds. There are no tension stresses in the base of the buttress; the compression stresses vary from 18 pounds at the heel to 311 pounds at the toe. The tension stresses in the arches are negligible when the reservoir is full, but when the reservoir is empty some tension develops due to temperature. This

Highest Multiple Arch Dam in World to be Located Near Phoenix, Arizona

Lake Pleasant Structure Will Rise Total of 250 Feet from Bed Rock

THE LAKE PLEASANT Dam, located near Phoenix, Arizona, and now under construction for the Maricopa county municipal water conservation district No. 1, across the Agua Fria at the site formerly known as Frog Tanks, when completed, will be the highest multiple arch dam in the world. From stream bed to parapet it will rise 170 feet, and below stream it will sink, in the deepest part of the subterranean channel, another 80 feet to bed rock, making a total height of 250 feet.

The second highest multiple arch dam in the United States, known as the Littlerock, was recently completed at Palmdale, in Los Angeles county, California, by J. G. Tripp, the superintendent of construction in charge here for Carl Pleasant, the contractor. It rises 170 feet above stream bed and is 725 feet long, as against 1975 feet of length across the crest of the Lake Pleasant dam.

Built for Irrigation

The duty of the dam is to impound 173,500 acre feet of water in a lake eight miles long and two miles wide for the irrigation of approximately 40,000 acres of land owned by the Beardsley Land and Investment company on the west bank of the Agua Fria river. The average annual discharge of the river, as measured over a period of 15 years, is 254-000 acre feet, of which it is estimated that 140,000 acre feet will be diverted for irrigation. The remainder will waste into the spillway, at times of high floods.

Twice in its known history, the river has risen to a peak discharge of more than 100,000 second feet, but the spillway gates will have a discharge capacity of 150,000 second feet. The plans call for 29 of them, each 23 feet wide by 16 feet high, set across a natural overflow channel situated about 750 feet northwest of the west end of the dam.

Economically Designed

No wastage is contemplated until the water behind the dam rises to a level within one foot from the parapet. Thus the maximum storage capacity of the dam will always be realized as nearly as possible or, to put it another way, the money invested in the dam will be earning the greatest possible amount. The dam, that is, was designed to do a maximum amount of work for a minimum of material and investment.

A multiple arch dam may be described as one relying for its strength, not on sheer mass and weight, but on the structural principles which enable an arch to absorb thrust on its crown and distribute overhead pressure through its piers and haunches to their supporting buttresses, bedded in the solid rock of the bottommost foundations.

The crown of the arch bulges upstream and slopes backward on its upstream face. The piers and haunches lie in the river bed, pointing down stream. The buttresses lie across the stream, and in turn transmit the stresses delivered to them into the natural containing walls of the river. The economy of materials thus effected more than offsets the greater difficulties of construction and the very much greater amount of carpenter work required to build forms.

Engineering Features

The spillway of the Lake Pleasant dam wastes into a second lake below the main storage dam, backed up against it by a diversion dam one and one-quarter miles farther downstream. When there is no wastage through the spillway, the impounded water behind the main dam is discharged through a six-foot valve into a 66-inch steel penstock 200 feet long and out again through a regulating needle-valve into the natural channel of the river. Two other outlets of the same diameter will be installed, for future power use.

Auxiliary Division Dam

The diversion dam, of rubble masonry and gravity type, will back up the water behind it 10 feet against the main dam above. Its function is to recapture and save for irrigation use any water employed in the generation of power or passed through the main dam via the penstock and regulator valve. Out of this second lake opens the main irrigation canal, on the east side of the river, with a carrying capacity of 500 second feet.

Four miles downstream the canal crosses the river to the west shore in a metal flume supported by timber trestles continuing for another eight miles to the

(Continued on Page 36)

Facts Regarding Building of New Lake Pleasant Dam

Following are the principal financial and physical facts underlying the construction of the new Lake Pleasant irrigation and power dam across the Agua Fria river at the Frog Tanks site:

Amount of money available for completion of entire project	$ 3,325,000
Date on which proceeds of bond issue became available	March 11,1926
Storage capacity of dam, in acre feet	173,500
Amount of power to be generated annually in k. w. h.	23,000,000
Acres of land to be irrigated	40,000
January flow of river (maximum month) in acre feet	701,000
Maximum flood flow, in second feet	105,000
Minimum recorded flow, in second feet	0.60
Delivery capacity of diversion canal, in second feet	500
Length of main diversion canal, in miles	35
Aggregate length of lateral canals, in miles	60
Maximum height of main dam from bedrock, in linear feet	250
Maximum depth from stream bed to bedrock, in linear feet	80
Thickness of dam at bottom of longest buttress, in linear feet	253
Length of dam proper across crest, in linear feet	1,975
Length of spillway, approximate, in linear feet	750
Discharge capacity of spillway, through 30 gates, second feet	150,000
Bulk of dam, in cubic yards of concrete	75,000
Number sacks of cement used in mixing concrete	500,000
Weight of reinforcing steel used, in tons	1,200
Amount of excavation from river bed, in cubic yards	80,000
Amount of excavation for spillway, in cubic yards	30,000
Amount of excavation for masonry diversion dam	1,600
Amount of excavation for canal and laterals, in cubic yards	1,700,000
Total excavation for main dam and spillway, in cubic yards	115,000
Grand total of all excavation, in cubic yards	1,900,000

THE MELONES DAM, WHICH WAS DEDICATED ON ARMISTICE DAY, 1926, MARKING THE HAPPY END OF A LONG STRUGGLE OVER CONFLICTING WATER RIGHTS

Melones Dam Completion Ends War Between Districts and Power Companies

Financial and Construction Details of Project Concluded November 11 Make Absorbing Story of How Co-operation Has Succeeded Enmity

By LOUIS MEYER

NOVEMBER ELEVENTH was a date well chosen for the dedication of the Melones reservoir by the Oakdale and South San Joaquin Irrigation Districts, for as Armistice Day of 1926 marked the end of the World War eight years before, so the completion of the big dam meant the finish of years of conflict between the farmers and the power companies, each claiming rights upon the Stanislaus River, in Northern California.

The Oakdale and the South San Joaquin Irrigation districts succeeded to water rights which were among the earliest in California, the old San Joaquin Valley and Canal Company and the Stanislaus Consolidated Water & Power Company (known as the Tulloch system) acquiring the water rights, but not the electric system, seventeen years ago.

Until nearly eight years ago, there was a continued difference of opinion between the irrigation districts and the Sierra & San Francisco Power Company, which took over the electric system belonging to Tulloch, and which built its own reservoirs in the mountains above Sonora for generating power. In 1918 the first step in co-operation was taken, when the districts agreed to buy the stored water owned by the power company at seventy-five cents per acre foot, per annum.

Today this co-operation is carried to its logical conclusion, the dedication of the dam last November marking the end of the fight over water rights on the Stanislaus, and ushering in a new era of development in the irrigation districts affected.

Novel Financial Arrangements

The contract signed two years ago on the one hand by the Sierra & San Francisco Power Company and the Pacific Gas & Electric Company to whom the Sierra system had been leased, and on the other hand by the Oakdale and South San Joaquin irrigation districts, provided in brief that the two districts should build a dam at Melones reservoir, to cost $2,200,000, and to hold 112,000 acre feet of water, and that the power companies should build a power plant to cost $2,500,000, a mile below the dam site.

Under the agreement the power companies are to have the use of the stored water for conversion into electric energy, and are to reimburse the districts for the amounts expended in construction of the dam, both interest and principal, through payments over a period of forty years.

In substance the farmers receive the water required for late irrigation without cost, other than lending their credit for construction of the dam.

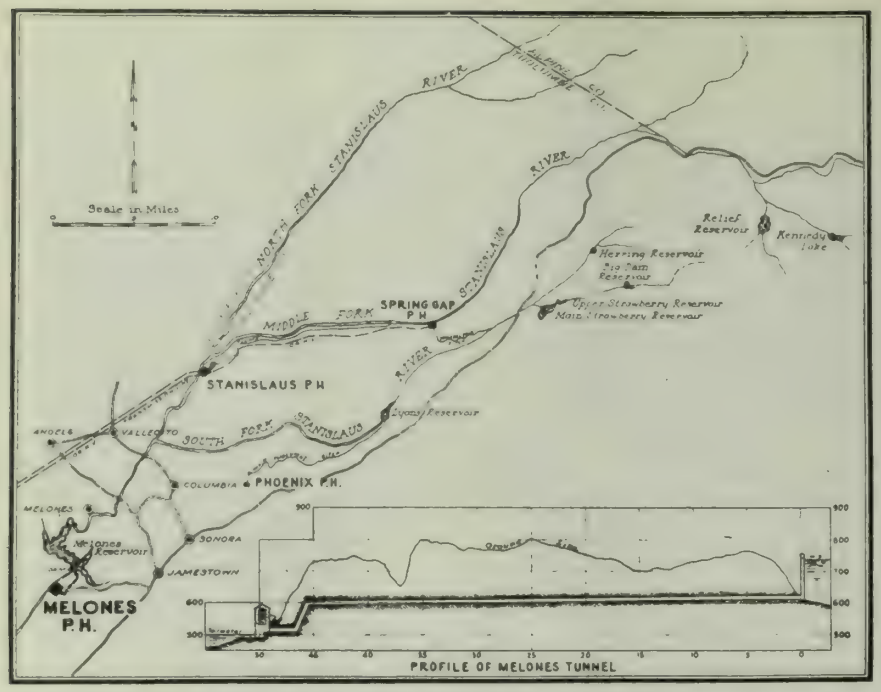
When the bond issue was submitted to the voters the directors promised that the additional storage water would not cost them a cent, and that their tax rate would not be increased, because of the favorable agreement with the power companies. This promise has been kept —even in the face of delay in completion of the big dam.

Difficulties Overcome

Like all irrigation districts, the Oakdale and South San Joaquin have had their trials and tribulations. The seventeen years since organization have been years of struggle. But the districts have never defaulted in their interest, and they have never assumed an obligation that they were unable to carry out.

The average citizen is always more or less suspicious of corporations, and the farmers in the two districts have in the past shared in the general disposition to doubt the good intentions of the power

"Western Waterworks" Begins on Page 25 ☛



companies. For many years there was a condition somewhat resembling an armed neutrality between the irrigation districts and the old Sierra & San Francisco Power Company over their respective rights upon the Stanislaus river.

The question of the priority of the districts' water rights was always a source of trouble. Although the farmers had first rights to the natural flow of the river, they contended that the water stored by the power company also belonged to them, and were fearful at times that they were being deprived of some of the natural flow of the stream as well through its being impounded in the Sierra reservoirs.

After years of rather acrimonious discussion, the districts finally agreed to recognize the ownership by the power company of the stored water. Then followed a contract by which the farmers paid seventy-five cents per acre foot for the water reelased for their use, as has been described.

What the Contract Provides

It was natural, then, when finally the directors obtained from the Sierra & San Francisco Power Company and the Pacific Gas & Electric Company an agreement by which these corporations would in turn pay the districts, practically at the rate of $1.25 per acre foot, for the water to be impounded at Melones reservoir, that opposition arose—it seemed too good to be true.

In the meantime the irrigation districts had refused, by a heavy majority of votes, a proposition for the purchase of the dam site alone from the Calaveras Copper Company for $125,000. The districts were not then ready to go ahead with storage development—they saw no means of financing expensive reservoirs.

So the contract, which after months and months of negotiations, was signed and sealed and which needed only the approval of the voters at a bond election, was far better than the ranchers had reason to expect. Storage had always meant to them additional taxation —and they had suffered already from excessive taxation, since the war. They read and re-read the proposed contract—meanwhile listening to an aggressive minority demanding that the districts develop their own power and actively fighting the proposed bond issue of $2,-000,000.

The majority of the land holders, however, sensing the fact that they had no market for the power aside from the power companies' offer, and doubting the wisdom of embarking in enterprises outside of irrigation, approved the bonds by a 26 to 1 vote in the Oakdale district, and 3 to 1 in South San Joaquin Irrigation district.

This contract marked an entirely new relationship between farmers and power interests—partners in a joint, commonsense enterprise from which both might benefit.

Both use water—stored water—and it had occurred to them that the expenditure of two millions of dollars when one million would suffice, was foolish and unnecessary.

The terms of the contract are exceedingly plain. They provide that the districts shall build the dam, at an estimated cost of $2,200,000, and that the power companies shall repay them for their expenditures a total of $5,175,000, on a basis of $1.25 per acre foot. This sum, paid over a term of forty years, pays both interest and principal of the bonds.

The districts agreed to vote the needed bonds, which was done May 18, 1925.

The districts agreed to build a reservoir to impound 112,500 acre feet of water, which has been done. They agreed further to provide rights-of-way and a site for a power house to be built by the Sierra & San Francisco Power Company, upon which the power companies agreed to construct a power plant with a maximum capacity of 30,000 kilowatts. Construction is now under way on this power house.

From March 1 to October 31 of each calendar year the districts have exclusive control of the reservoir and water therein, and from November 1 to March 1, the power companies control the reservoir, it being agreed that at no time shall the draft upon the reservoir exceed 1700 cubic feet per second (the maximum requirements of the districts); the power companies agreeing also to permit the storage of 36,000 acre-feet prior to March 1, at Woodward reservoir of the South San Joaquin district.

In addition, the power companies agree to release, for the use of the districts, and without charge, any waters they may store in reservoirs already constructed or hereafter to be built upon the Stanislaus river.

More Storage Available

By virtue of this clause the districts secure, in addition to the 112,000 acre

Water Service Extension in the Vista Irrigation District—a Business Solution

By GEORGE S. HENRY
Former President Vista Irrigation District

THE territory served by the water system of the Vista Irrigation District in Northern San Diego County is generally rolling. Climatic conditions and other factors favor the subdivision and settlement of exceedingly small acreages with a consequent eventual dense rural population. The ultimate development will be for citrus, avocado, sub-tropicals, etc., with a large percentage of off-season and winter vegetables during the first years.

The plans for primary construction contemplated the distribution of water to the high point of each 40-acre tract only throughout the district, and this water service was completed on schedule. The board of directors early realized that an opportunity existed in the district for the exercise of business foresight coupled with business methods, in speeding up the transition from a sparsely settled and generally undeveloped section, such as comprise most irrigation projects, to a going concern, promptly utilizing its water resources and developing its economic opportunities through successful and competent colonization. The necessity was very apparent—the means afforded by statutory handicaps not so very clear. After a thorough study of the type of future development likely to take place here and as the greatest single aid, the board devised a plan to extend water service to ten-acre tracts as will be detailed later.

Board's Proposal

It was apparent that good business and proper regard for economy demanded a progressive extension of this 10-acre service, on an orderly plan in step with development needs. A fortunate and somewhat unusual cash saving made in the original construction, plus a substantial reserve in bonds set up at the time construction bonds were voted, provided an ample fund with which to finance the program. A circular letter was addressed to each land owner within the district by the board proposing briefly as follows:

That the District will build such necessary extensions to its system of laterals that water may be delivered to each tract of ten or more acres of irrigable land within said District, the owners of which tracts will comply with the following necessary regulations:

First: If such extension is made during the calendar year 1926, the owner of such tract or tracts shall pay into the treasury of said District the difference between the estimated cost of such extension and an amount equivalent to fifteen dollars ($15.00) per acre for each irrigable acre owned by the owner so applying.

Second: If such extension is made during the calendar year 1927, the owner of such tract or tracts shall pay into the treasury of said District the difference between the estimated cost of such extension and an amount equivalent to eleven dollars ($11.00) per acre for each irrigable acre owned by the owner so applying.

Third: If such extension is made during the calendar year 1928, the owner of such tract or tracts shall pay into the treasury of said District the difference between the estimated cost of such extension and an amount equivalent to seven and 50-100 dollars ($7.50) per acre for each irrigable acre owned by the owner so applying.

Fourth: Each owner so applying for such extensions shall grant to the District easements and rights of way for the laying of such proposed extensions. All laterals or pipe lines so extended under this proposal shall be the property of the Vista Irrigation District.

Fifth: Each owner so applying for such proposed extensions must either have already expended or agree to the satisfaction of the Board that he will expend in improvements upon the land to be served an amount equivalent to fifteen dollars ($15.00) per irrigable acre. The term "improvements" as used in this paragraph shall be construed as meaning leveling of the land or preparing the same for irrigation or planting or proper preparation and cultivation of the soil and the planting of trees and for the laying out of pipe lines or distribution lines, or such other improvements as render the land to be served susceptible of beneficial irrigation and utilization of irrigation waters, or such term shall be construed to mean the subdivision and platting of said land and filing of said plat of record and the approval thereof by the County Engineer and Board of Supervisors of San Diego County, as provided by law, together with necessary and requisite laying out and construction of roads and highways. The owners of land within said District shall have the option of the manner of expenditures for improvements as herein specified. The erection of buildings upon the land shall not be considered as improvements within the meaning of this paragraph.

Sixth: The laying out and construction of all such laterals and extensions shall be done by the District and shall be under the direction of the Engineer of the Vista Irrigation District and shall be laid out in such manner as said Engineer shall deem for the best interests of the land and of the District.

Seventh: In case the expenditures for improvements shall not have been made prior to the application for such extension the owner so applying shall enter into an agreement satisfactory to the Board of Directors that such expenditures will be made within one (1) year from the date of such application, which agreement shall provide that in case of the failure to make such expenditures for such improvements as contemplated by this resolution, and to the satisfaction of the Board of Directors of this District or its Engineer, that the owner of said land shall forthwith pay into the Treasury of the District the amount expended by the District in the construction of such extension, and that the District shall have a lien upon the property so to be served by such extension for the repayment of such money.

Eighth: Before commencing the work of construction of such proposed extensions, the owner so applying shall deposit with the Treasurer of said District a sum sufficient to cover the amount to be contributed by him toward such construction, the amount of such deposit to be determined by the Engineer of the District. Upon the completion of such construction, any surplus over and above the amount to be contributed by such owner remaining in the hands of the Treasurer shall be forthwith returned to such owner

As definitely determined by the Board, extensions of pipe lines to less than 10 acre tracts of irrigable land cannot be made by the District. Where owners of less than ten acres desire extensions, it is suggested that they attempt to secure the cooperation of adjoining neighbors, or ask the Manager of the District for advice in the matter.

Prior to inaugurating this novel program, a test case was prepared and tried in the Superior Court of San Diego County, California, before Judge Cary who affirmed the legality of the board's action.

Plan Is Succeeding

Not only did the board have in mind the objective of bringing water service as near as possible to the ultimate consumer with the consequent better financing of the major cost of these necessary extensions through district credit, but by the foregoing procedure the board through its engineer will obtain eventually the general oversight and supervision of the subdivision plans of every tract in the district. The importance and necessity of "planning supervision," for which the law makes no provision, is apparent to anyone having had to do with the orderly development of as extensive a territory (17,600 acres) as embraced in the Vista Irrigation District, where very complex factors enter into the laying out of subdivisions suitable for proper irrigation, cultivation, avoidance of erosion, etc. Next to the direct financial benefit afforded the developer, this supervisory feature is of secondary importance only.

As practically no development had been possible prior to the completion of the system, and in view of the fact that the district was obligated to take any pay for a definite quota of water during the current and succeeding years, as detailed in a former article, the graduated scale of cash allotments was de-

Vol. II DECEMBER, 1926 No. 12

A Business Proposition

IT IS conceded that the irrigation district provides, generally, the best and most feasible vehicle yet evolved for the financing, development and management of co-operatively owned irrigation enterprises Although viewed with little approval by the government reclamation officials in the earlier stages of the government's irrigation ventures, time has demonstrated the utility of this agency and the irrigation district has become the ultimate legatee of a government project.

The irrigation district is the logical expression of American democratic ideals and vests in a community in concrete form, the ownership and management of its basic utility. That the California statutes governing the organization and conduct of these organizations are faulty to an exasperating degree, and that some reform or reenactment can not much longer be postponed is very patent.

Irrigation districts are termed "quasi-municipalities" and in certain respects they conform to the municipal pattern. But the financing, construction and management of an irrigation enterprise involves successful combining of raw materials—land, usually in a raw or 'rare' state, and water—into a product to be utilized by a purchaser or purchasers for profit. That resembles a business enterprise more closely than municipal administration.

Boards of directors face, therefore very real business problems demanding business judgment, business foresight, and business initiative and courage. The present irrigation district statutes give very little direct, unequivocal encouragement or sanction for the exercise of such qualities, but still the inherent problems must be faced and solved successfully or disaster follows. The statutes enjoin on a board of directors the duty to so administer and conduct the affairs of a district as to accomplish the purpose and intent of the act; i. e., furnish water successfully and satisfactorily to the lands within a district. The injunction is plain and mandatory.

Faced with this responsibility, the directors of the Vista Irrigation District, through the counsel of their legal advisor, adopted a "rule of reason" policy and applied to their problems the same business methods and decisions that would be employed in a private enterprise of like character, except, of course, where directly prohibited by statute. In an article appearing in a former issue of MODERN IRRIGATION, and in one in this issue, are set forth solutions of practical managerial problems adopted by one of the newest but seemingly most progressive districts in the state. The direct results of these policies apparently have justified the business thought and initiative expended.

Corrosion's Toll

THE toll exacted by electrolytic corrosion, or electrolysis, from many industrial enterprises in our larger American cities runs into a fabulous sum yearly. It is almost impossible to estimate this loss in figures, but millions of dollars would be conservative. This economic waste which could be eliminated by the proper methods of correction, will undoubtedly be a subject for extensive treatment during the years to come. When one realizes the extent of the damage inflicted by these small stray currents, the need for corrective action becomes easily apparent.

It has been, and still is, common practice for street railway and traction companies to use the ground as a return conduit to the generating plant or sub-station. Of course, electricity will follow the line of least resistance to its objective, and if the return provided offers higher resistance than some other course, the latter one is naturally followed. As a general rule, this latter course is along some metallic pipe line or conduit used by the municipality or one of the other public utility companies operating in that vicinity.

Some of our more progressive cities, as for example, Washington in the District of Columbia, have already established corrective measures by proper legislation. Street railway companies or traction companies are granted their franchises upon condition that they take the proper precautionary measures stipulated by the government for

"Western Waterworks" Begins on Page 25

POINT *Of* VIEW

the prevention of electrolysis. In this particular instance, they are required to use an independent line to the generating plant; that is, instead of a single trolley wire, a double line is used, thereby providing a conduit which does not come into contact with the ground. The generators at the sub-stations are not grounded, but connected to this independent return, and in this manner the currents are confined to a single path, which eliminates at the source any stray currents that might otherwise be generated. All electric motors operated within the limits of the district are provided with independent lines, and in no case is the ground used as a return. This applies to all industrial motors, such as elevator motors, factory motors, etc.

Undoubtedly it would be a costly procedure to make the proper corrections in most of our American cities at this particular stage of civic development, but the time is coming when such action will be absolutely necessary, and it would be well for the engineering fraternity to lay their future plans accordingly.

Solving a Sewage Problem

THE sanitary disposal of the trade wastes from many industrial plants is one of the biggest problems of the sanitary engineer. The advent of the activated sludge process and its application to trade waste problems, has opened up a new field for investigation. It is found that some of the wastes can be successfully treated by this method if mixed with domestic sewage, but not if treated separately without excessive costs for chemical precipitation. This is a problem which varies with individual plants and must be solved by local study of each particular trade waste.

There is no doubt but that the trade waste problems of many cities could be solved by properly designed activated sludge plants and that further studies will perfect methods for treatment of wastes not at present successfully treated.

The comparatively high cost of activated sludge plants has been one of the main objections to their adoption. The mechanical types show a power economy and require less labor attendance. So far data on the depreciation charges for this type are too meager to warrant any definite conclusions. It would seem that some form of mechanical aeration eventually will be found that will be the most economical form of activated sludge plant, especially for small installations.

The initial cost of an activated sludge plant is no greater than that of other methods giving as high grade of effluent.

The higher operating cost of activated sludge plants over other methods is due to more mechanical devices, higher power costs, and a greater labor overhead. The cost per million gallons, including depreciation, interest, labor, power, etc., has been found to run from $20 to $50 in the few plants where data are available. The initial cost of the plants varies from $10 to $30 per capita.

The wide variation in these cost figures serves to emphasize the fact that each municipality has a separate sewage disposal problem of its own and that cost data of other cities may not be at all applicable. Thorough preliminary investigation is necessarily to economically design a sewage disposal system, whether it be an activated sludge plant, or one of the other types. High operating, repair and alteration costs of many plants are directly due to a lack of preliminary investigations.

The New Pump Contract

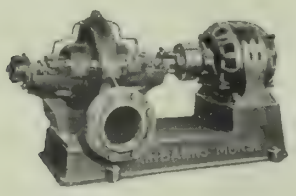
ELIMINATION of waste in industry through standardization of methods and machinery, is a goal toward which marked progress has been made in the years since the war. This progress has been manifest in the automobile business, in the oil business, and other businesses where economic laws make success dependent on reducing waste to a minimum.

In the field of irrigation and waterworks in California the effort made during the last three years to standardize on a purchase agreement for deep well pumps is a notable development in this movement to eliminate waste. The recent completion and approval of such an agreement by the Western Irrigation Equipment Association and the Pacific Hydraulic Engineering Association, marks a milestone in standardization development. It is an agreement that attains an objective none too easy of accomplishment; it is a fair proposition both to seller and purchaser.

Before this purchase agreement can become standard practice, however, its approval by the California Farm Bureau Federation, as well as the University of California Agricultural College and the California Bankers Association, is essential. These bodies are studying the standard contract form and the hope has been expressed that within another year, the agreement will have met with the approval of all the agencies necessary to its general adoption.

Credit for the initiation of the plan to standardize on a purchase agreement for deep well pumps and the bringing of that plan to its present stage of realization must go to the Western Irrigation Equipment Association, certain members of which have given unreservedly of their time in the last three years in order that the idea might become an accomplished fact. We feel that the general approval of the agreement is merely a matter of time. The fairness and practical value of the agreement cannot be denied.

"Western Waterworks" Begins on Page 25



How much attention should pumping equipment require?

Take the Fairbanks-Morse pumping unit illustrated above. This motor pump outfit requires about the minimum attendance imaginable. Lubrication, for example, is a simple matter of greasing the bearings at six month intervals. Practically no other attention is needed. Every bearing is a ball bearing, which means that friction and wear are practically eliminated. The shaft is carried on permanently true centers and the proper running clearance is maintained between impeller and wearing rings.

This unit is typical of other Fairbanks-Morse pumping equipment that is setting new standards of dependable, economical operation and long life in irrigation service. One advantage of using Fairbanks-Morse equipment that has appealed to many irrigators, is the fact that a complete Fairbanks-Morse installation can often be used—all pumping and power equipment furnished by one manufacturer with no split in the responsibility for satisfactory service.

Whatever your requirements, investigate Fairbanks-Morse equipment for filling them. The advice of our engineers is always available. Write the nearest branch for bulletins and other literature.

Coolidge Dam Interesting Innovation

(*Continued from Page 12*)

amounts to a maximum of 140 pounds per square inch. For this reason, while no steel is required when the reservoir is full steel is added, to take care of the temperature deformations and to tie the structure together. Steel reinforcement is also used in that portion of the dome forming the bridge and in the shoulder of the dome to provide for the shear induced by the bridge and the unsupported section of the dome. Although no steel is required in the buttresses, some is used to overcome the possible effect of shrinkage in the line of action of least stress. The sliding factor of the dam when the reservoir is full is 0.73 without uplift; with 50 per cent uplift at the heel diminishing to zero at the toe of the buttresses, it is 0.76. The overturning factor with the reservoir full without uplift is 2.83, with uplift 2.00.

In the design, as precaution against uplift, the foundation will be grouted; the dam will be anchored to its base and provided with inspection and drainage galleries. The stability factors conform closely to the usual custom and could be increased if considered desirable by giving the dam a flatter slope, but it is believed at a sacrifice of economy.

Estimate of Quantities

It is proposed to use a 1:2:4:2 concrete in the arches, 1: 2½: 5: 2½ mix in the buttresses which before the dam receives its full load should develop strengths of at least three thousand and two thousand five hundred pounds per square inch respectively, corresponding roughly to a factor of safety of five against crushing.

Owing to the massiveness of the dome type, the cost of the forms per cubic yard is comparatively low.

The estimated quantities of materials required for the construction of the dam are as follows:

Excavation: Sand, gravel (cu. yds.)..		26,000
Excavation: Dry, dam base and spillways above elecation 2316 (cu. yds.)	195,000	
Excavation: Wet rock, dam base below elevation 2316 (cu. yds.)	14,000	
Total Rock Excavation (cu. yds.)		209,000
Concrete (buttresses) (cu. yds.)	83,000	
Concrete (domes) (cu. yds.)	73,100	
Concrete (spillway floor, walls, and gate settings) (cu. yds.)	13,500	
Concrete (bridges over dam, on road to powerhouse, to outlet towers) (cu. yds.)	10,330	
Concrete (outlet towers) (cu. yds.)	2,300	
Concrete (power house base and house) (cu. yds.)	7,200	
Concrete (gunite and grout) (cu. yds.)	1,500	
Total concrete (cu. yds.)		190,930
Cement (bbls.)		223,300
Steel (reinforcing) (tons)		2,250

Exclusive of bridges and other items not common to the several types, the percentage of cost and quantities of concrete which the multiple dome dam bears to the other types of dam investigated are as follows:

Type of Dam	Per cent of Cost	Per cent of Quantity
Rock fill	74	...
Variable radius	89	62
Arch gravity without uplift	83	52
Arch gravity with 50% uplift	71	43
Multiple Arch	98	150

As a specific example it may be mentioned that the total concrete in the multiple dome dam is 156,100 cu. yds. as compared to 367,000 cu. yds. in the curved gravity dam figured with similar uplift.

While the estimated cost of the Multiple Arch type was in excess of the dome, the difference was too slight to be of any great importance. The two had also approximately the same stability factors and working stresses. The important difference lay in the fact that there was considerably more concrete in the Dome than in the Multiple Arch type, which rendered it more massive, with a probability of greater stability and permanence. The Dome type had such further security as the domes might afford and also possessed the advantage of being readily adapted to the development of electric power.

During the preparation of plans and estimates for the Coolidge Dam the designers had the assistance of a board of consulting engineers consisting of L. C. Hill and F. A. Noetzli of Los Angeles, California, and the firm of Wright and Gentry, architects of Los Angeles and Long Beach, were secured to design the architectural treatment. A second board of consulting engineers, consisting of General L. C. Langfitt of New York and A. J. Wiley of Boise, Idaho, was appointed to pass on the plans when they were complete. After a careful investigation this board recommended the construction of the multiple dome dam at the Coolidge site, and the plans were finally approved by the Secretary of the Interior May 8, 1926. Since the multiple dome dam is a new type the designers thus were fortunate in having two boards of eminent consulting engineers to pass on their work, all of whom belong to the American Society of Civil Engineers and are too well known to require special comment.

The Pacoima Dam, Los Angeles County, California, now in process of construction, proved its value during recent rains, according to a statement by G. H. Wray, engineer in charge. The impounded waters at the base of the dam measured 60 feet in depth and ran back a distance of 800 feet.

Standard Purchasing Form for Deep Well Pumps Gets O.K.

Progressive plans were made at the last meeting of the Western Irrigation Equipment Association, held the 19th of November, at San Jose, Calif., for the promotion of a new group of buildings for the California state fair grounds at Sacramento, to house the exhibits of the farm machinery and equipment manufacturers. Heretofore, such exhibits have been placed in tents rented by the state, and were very unsatisfactory from many standpoints.

E. F. SEWELL

Who has succeeded C. A. Utley, resigned, as secretary of the Western Irrigation Equipment Association. Mr. Sewell is associated with the Martin Iron Works, Los Angeles.

The association reported a very successful year. Probably the oustanding accomplishment of the twelve months was the completion of a standard form to be used in the purchase of deep well pumps. This form has been approved by the Pacific Hydraulic Engineering Association and Western Irrigation Equipment Association. It is a milestone in the merchandising history of farm equipment, and is fair to both seller and purchaser. A copy of this agreement may be obtained by writing the secretary of the association, E. F. Sewell, Martin Iron Works, Los Angeles.

The evening session of the meeting was started with a banquet, the toastmaster being Frazier O. Reed, of San Jose. At the close of the banquet papers were presented by Max Watson, Prof. R. L. Adams, and Fred C. Scobey.

Melones Dam Completion Significant Event

(*Continued from Page 16*)

feet stored at Relief, both reservoirs owned by the power companies. Since the signing of the contract the Sierra & San Francisco Power Company and the Pacific Gas & Electric Company have announced plans for a 53,000 acre feet reservoir to be built at Big Dam, above Strawberry, and a 7,000 acre feet reservoir to be built at Herring Creek. This will give the districts a total storage of practically 200,000 acre feet, sufficient for all future development.

The contract provides for the payment of the total sum of $5,175,000 in forty years, in semi-annual amounts of $64,687.50, each district to receive one-half. The first payment under the contract was expected to be made December 15 and semi-annually thereafter until the entire amount has been paid.

Still another clause makes the signing of the agreement mark the end of the dispute as to water rights on the Stanislaus river. All rights are declared settled, and the adjudication of the California Department of Public Works is accepted as final.

Following the election the districts immediately offered the bonds for sale, and placed the entire issue practically at par. The acceptance of the 5 per cent bonds at such terms was doubtless due in large measure to the double security of the assets of the two irrigation districts, and the contract by which the Pacific Gas & Electric Company agreed to pay the interest and principal. Since their original sale, they are now being sold on a 4.75 basis, showing the soundness of the co-operative agreement from a strictly financial standpoint.

Construction Began in July

On July 14, 1925, the contract for the construction of the dam, railroad and wagon-road was awarded to the Mathews Construction Company of Sacramento, at a round figure of $1,431,000. The total did not include certain materials which the districts agreed to furnish, nor the rights-of-way, which will bring the grand total to $2,200,000, the estimate of the engineers.

Work was started a month later, the contract calling for completion of the dam by March 15, 1926. Delays arising in difficulties in controlling the Stanislaus River prevented the completion of the dam in time for this year's irrigation, but two months ago the districts stored their first water behind the mass of concrete.

No fears are entertained but that there will be plenty of water available to fill the dam this winter.

The districts have water rights on the Stanislaus river consisting of 1046 second feet natural flow of the river, plus 770.6 second feet storage rights, making a total of 1816.6 second feet. Statistics show that the average annual run-off of the Stanislaus river is 1,300,000 acre feet, and that the water requirements of the two districts, when fully developed, are 560,000 acre feet, one-half the normal run-off.

The dam is 210 feet above bed rock. It is of the constant-radius arch type, the designs and plans having been prepared by A. J. Wiley, consulting engineer, of Boise, Idaho, who is one of the most eminent dam builders in the United States. Mr. Wiley designed the Don Pedro and Exchequer Dams, both recent construction projects in the San Joaquin Valley.

The length of the dam on the crest is 585 feet. The thickness at the base is 107 feet. Thickness at crest is 24 feet—radius 228 feet. Mass concrete in the dam amounts to 90,000 cubic yards —80,000 barrels of cement were used in the concrete. The foundation excavation was 32,400 cubic yards.

The outlet from the reservoir is controlled by six 2½ feet by 8 feet gates in the outlet tower, discharging into a concrete lined pressure tunnel through which both irrigation and power demands are supplied.

The tunnel is eighteen feet in diameter for a distance of 415 feet below the headgates, where four 60-inch (Johnson type) needle valves, with a capacity of 2,000 second feet, tap the tunnel for irrigation use. The power company is now constructing a 12-foot tunnel with a capacity of 1500 second feet, 4,000 feet in length, from the end of the districts' tunnel to their power plant, located down stream from the dam at the end of Iron Canyon Gorge.

Construction Details

The spillway for by-passing the flood waters provided over the rest of the dam consists of nine drum type spillway gates, each 12 feet in height by 57 feet in length. The combined weight of metal in the drum gates is over 600,000 pounds. They are the largest gates of this type ever constructed. The spillway capacity is double the maximum recorded flood of 20,000 second feet. Melones is the highest over-pour dam in the world.

The back water in the reservoir extends up stream from the dam site for a distance of twelve miles, submerging approximately 2,000 acres of land and creating 112,500 acre feet of storage.

To build the dam it was necessary for the districts to build a railroad 8½ miles in length, extending from Jack Siding on the Sierra Railway to the dam site. This required excavation of 97,000 cubic yards, mostly rock. The districts own and operate the last 2½ miles of railroad, using a Shay locomotive becaues of the sharp turns. The gravel for the dam was hauled from the Atlas Rock Company plant near Oakdale, the districts purchasing eight 80,000-pound gravel cars for this purpose.

It also required construction of a wagon road, 3½ miles long, to haul the materials for preliminary work into the dam site. The estimated cost of the dam, including the railroad and wagon road, was $1,657,000, which did not include the rights-of-way.

The construction of the dam was the work of the Mathews Construction Company of Sacramento, and the construction program has been carried on under supervision of George K. Parker, as superintendent, and H. L. Leventon, assistant superintendent.

In addition to A. J. Wiley of Boise, Idaho, who designed the dam and has been the consulting engineer, the technical staff includes R. E. Hartley of Oakdale, chief engineer; C. L. Riley of Manteca, associate engineer; George D. Macomber of Oakdale, resident engineer, and Vern L. Peugh, assistant engineer.

Gillespie Dam Is Sold

The Gillespie Irrigation project, lying about 60 miles southwest of Phoenix, has been sold to an Eastern syndicate for about $5,000,000, according to announcement recently made. The purchase includes over 80,000 acres of land north and west of Gila Bend, a forty-mile canal and a multiple arch diversion dam across the Gila river. The project is one dating back to the early '90's, promoted by Lewis Wolfley, then territorial governor of Arizona. At the time of sale title was held by the Gila Water Company, in which the president and principal stockholder is F. A. Gillespie, of Los Angeles.

Credit to A. W. W. A.

In three instances in its last issue Modern Irrigation failed to give credit to the California Section American Water Works Association for papers printed in that issue and previously read before the annual meeting of the California Section at San Diego. Mention should have been made of the fact that the articles by William Mulholland, J. H. Fagg and Dr. Carl Wilson were originally read as papers before the waterworks convention and reproduced in Modern Irrigation through the courtesy of the editor of the Journal of the American Water Works Association.

Problems of a Sub-Surface Water Supply

With Particular Reference to the Lindsay Strathmore Irrigation District, California

By GEORGE W. TRAUGER
Superintendent, Lindsay Strathmore Irrigation District

THE Lindsay Strathmore Irrigation District was organized on November 9, 1915, under the "Irrigation District Act of the State of California." It extends from the Southern Pacific Railroad on the west, eastward to the westerly slope of the Sierra Nevada Mountains, and from a point three miles north of the town of Lindsay, southward to Strathmore. Its boundaries are irregular. Its gross area is slightly over 15,000 acres. The district lies wholly within Tulare County. Prior to the year 1900 the land now within the district was used either for dry farming or allowed to be fallow. By 1903, five hundred acres of the area had been planted to orange trees, many of which were in bearing. These plantings showed that valuable citrus crops could be produced by irrigation with water pumped from underground sources. As a consequence, the development from 1903 to about 1914 or 1915 was rapid, and by the end of 1914, over 7,000 acres had been planted to citrus crops. Of these about 6,000 acres were in full bearing. Practically all of the San Joaquin Valley is semi-arid, in the sense that irrigation is necessary to the profitable production and this is particularly true of that portion of the valley now known as the Lindsay District. The increased draft on the water sources to serve this additional planting, so lowered the water table that the supply showed evidences of depletion as early as 1912 or 1913, and by 1915 the water supply had given out entirely in some areas, and in others it had become so salty that its use for irrigation purposes became injurious, if not absolutely destructive of the crops and trees to which it was applied.

It therefore became necessary for the land owners to acquire other water sources from which a sufficient supply could be obtained. Otherwise the area about Lindsay would revert to desert conditions of earlier days. About ten miles north of the town of Lindsay there was found a tract of land lying on both sides of the Kaweah River, known as the Rancho de Kaweah, and consisting of coarse sand and gravel filled to the surface with water. Opinions of competent engineers were obtained to the effect that sufficient water to supply the needs of the citrus groves

in and about Lindsay could be obtained by pumping from this underground basin, and relying thereon, the Lindsay Strathmore Irrigation District was organized in 1915; the Rancho de Kaweah was purchased, and thereafter thirty-nine wells, spaced at one-eighth of a mile apart, were bored, and are now and have been since the year 1918, pumped and the water obtained thereby transported to the lands within the Lindsay District.

About 12,000 acres of citrus orchards to the west of the Southern Pacific Railroad remained out of the district, feeling that their supply was ample and would hold out with the discontinuance of pumping on the east. About 500 acres located inside the district boundaries also decided to take a chance on their wells in preference to coming in. Practically all of these last mentioned lands exhausted their supply in a few years and have since been taken into the district.

This was done by buying unimproved lands within the district and thereafter excluding them and substituting the improved lands in their place. This entire project was approved by the State Engineer, and by several very well known engineering firms; bonds of the district were approved by the State Bond Commission, and were sold at or very near par. The outstanding bonds consist of two issues: the first issue in the amount of $1,400,000.00 sold at a premium; and the second issue of $250,000.00 sold at slightly below par.

Local History

The history of our water conditions is similar to that of many other parts of California. The area west of the Southern Pacific Railroad, before mentioned, is now finding that it also has a water problem. Its supply is greatly depleted; many wells have become salty; the water table has been lowered beyond an economic lift. This is due to several causes: First, many sections have developed by the use of underground waters, without any study of the amount available, and the possibility of replenishment. It should be the purpose of men who develop projects of this character to prevent over-drafts on underground basins. This is done by our State where districts are formed, but I have in mind cases where an individual will drill a well, get water and profitably raise crops; then another comes in, does likewise.

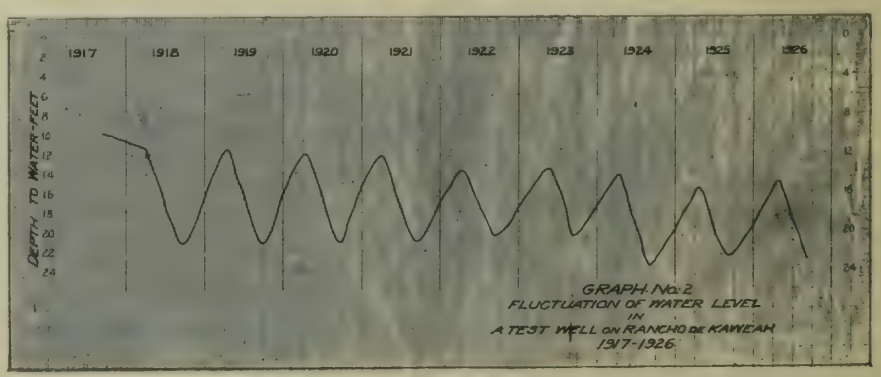
Some real estate company buys large tracts, sub-divides the same and sells to innocent purchasers on the strength of what this or these men have done. In the course of a few years there is not an adequate supply, and failure for many is the result. I favor either a state or even a county control of drilling wells. This may be impossible. There certainly should, however, be some control of men drilling wells, to protect the public. Enough money has no doubt been wasted by poor well drilling, poor equipment and unscientific methods, to build many good storage reservoirs. Many of these men don't even know how to keep a log of a well. I have known many cases where a rancher has drilled a well usually for convenience near his property line, sufficient for his needs; then his neighbor drills just across the line; then they play hide-and-seek with each other until one "goes broke." I know whereof I speak. I have lived on an orange grove, and still do, and have seen this very thing happen many times. The state keeps tab on the drilling of oil wells; why not on water wells?

Second: There must be a greater effort made to conserve our water in times of heavy run-off, both by building reservoirs, and when these are full by spreading as much as possible to build up the underground storage. This means a study of the underground basins, and means of replenishment. The great advantage of underground storage is not fully appreciated: In our own case, the past three years have amply demonstrated that where it is possible this is the best possible storage. We were able to meet our needs in a fairly satisfactory manner, when almost any other plan would have left us "high and dry." In many cases the underground storage basin is filled by fall and winter flows that otherwise would be lost, leaving available for spring and early summer irrigation a greater amount of water. For this reason a better study should be made and a systematic way worked out for the filling of these basins.

History of Kaweah River

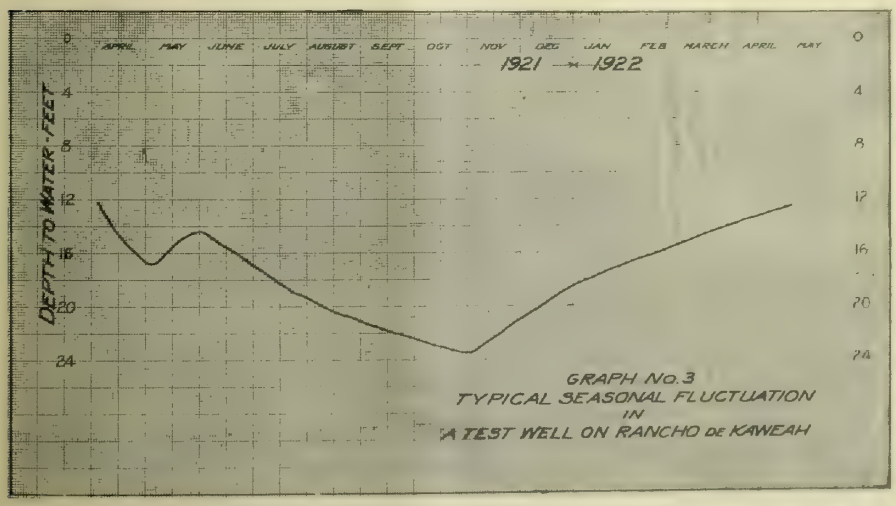
A condition that is true of the Kaweah River is also true of many other streams of California. This river, with a watershed of about 600 square miles, rises at the top of the westerly slope of the Sierra Nevada Mountains at an elevation of 10,000 to 12,000 feet. This stream with its tributaries has an annual run-off of about 450,000 acre feet. from 1915-16 to 1925-26 the average run-off was 295,000 acre feet. From 1906-07 to 1915-16 it was 458,700. This is 1,550,000 acre feet less than normal for the past ten years. These figures, which do not take into account the big year of 1905-06, account in a large measure for the present acute condition.

Curve No. 1 shows the fluctuations of a well southwest of Lindsay in a section that locally is considered good. The well, 240 feet deep and used only for a small domestic supply at the house,



is a good example. Measurements cover a period of 14 years. The ground surface is at an elevation of 370 feet. In 1912, the water in this well stood at 42 feet from surface. By 1918 it was 73.2 feet. By 1923 it was 111.7 feet, and in September, 1926, it was 133.2 feet from the surface. All other measurements were made in October. The graph shows intervening years.

Curve No. 2 shows the fluctuations of water in an index on the Rancho de Kaweah, and which is about a mile distant from the river. It is used for keeping track of the elevation of the ground waters. The purpose of this graph is to show how an underground reservoir will store and hold water, especially where there are often early fall rains which bring up the flow of the rivers, and heavy floods during the winter and spring. The fall and winter flows will replenish the basin, in most cases, before the water is needed in the regular irrigation period. This well is at an elevation of 411 feet, about ten feet higher than flood level of the river, and never according to our records subject to overflow. It is in an area where about 14,000 acre feet has been pumped out each year for the past eight years. It gives a good idea of how water can be stored, used and replenished. On April 3, 1918, before any pumping had been done in this area there being no wells closer



GRAPH NO. 3
TYPICAL SEASONAL FLUCTUATION
IN
A TEST WELL ON RANCHO DE KAWEAH

than two miles or more, the water in this well was 11.5 feet from the surface. On April 29, 1926, the water was only 14.9 feet from the surface. It must be remembered that in this section of the San Joaquin Valley, the years 1924, '25, and '26 were very dry, but with all this pumping and dry years, we only have a loss in ground water elevation of 3.4 feet. The graph shows the intervening years.

Too Much Water a Detriment

Curve No. 3 on the same well shows the draw-down over a period of a year, measurements being taken each month, and the year 1921 used—a normal year in rainfall, snowfall and run-off. On April 4, 1921, the depth to ground water was 12.3; by May 2, 1921, it was 16.8 feet; on June 1 it had come back to 14.4 feet, due to flood waters from melting snow, river over-flowing its banks. By November 2 it had reached its lowest point, 23.5 feet, and by April 7, 1922, it was back to 13.7 feet, and on May 4, 1922, it was 12.6 feet, or only .3 of a foot lower than the previous year. Many of these areas that are pumped have been greatly benefited by holding the ground waters below the root area of the growing crops and in many districts pumping is absolutely necessary to keep the ground from becoming water-logged.

At this point I wish to tell of the owners of 60 acres of orange orchard, who came in one day to find out if we would install a meter for them. They were part owners in a large well, the water was not measured and they felt they were not getting sufficient for their needs, or in fact their share of the water. I found out before getting through with them, that at the time they were planning to buy drainage pipe to draw off water, and that even the water they were getting was just twice what they needed for an orange grove, located as theirs was on very heavy soil. I had to show them some mighty fine groves, with a metered system, using the needed amount, to convince them. This only goes to prove, as I believe, that in very many cases ground waters are being used far beyond reasonable requirements, and in many cases to the actual injury of crops.

History of Litigation

A short review of the history of the litigation in which the Lindsay Strathmore Irrigation District is involved may be of interest. Furthermore, the effect of its final outcome upon our district may be of vital importance to other districts and municipalities. The original complaint was filed on the 15th day of July, 1916. Included among the plaintiffs were one irrigation district, 17 mutual water companies, and 56 individuals. The purpose of the action was to enjoin the Lindsay Strathmore Irrigation District from pumping water on

Continued on Page 16

Use of Water for Special Purposes Presents Big Field for Research

Data for Consumption in California Cities Is Presented to Stimulate Work Along This Line

By CHARLES H. LEE

Consulting Hydraulic Engineer, San Francisco

The Author's Conclusions

IN DOMESTIC service alone the depth seldom exceeds 2.1 feet per annum, including the irrigation of large beautified estates. For human needs alone the depth is less than 1 foot.

Industrial demand requires a maximum of possibly 5 or 6 feet depth per annum, although data is lacking for a definite determination.

In commercial districts the demand may run as high as 24 feet per annum.

The duty of water in irrigation varies from 1.25 to 4.58 feet per annum.

Graphical analysis of water consumption data on the basis of depth of water and density of population offers a method for comparative study which is simple and comprehensive.

"Service area acreage" should be added to the items listed in the Manual of Water Works Practice, as the least which a waterworks system should have (pp 433-4).

The making of special tests of the depth of water delivered in various types of waterworks service should be encouraged.

WATERWORKS reports are usually lacking in information regarding the use of water for special purposes, such as domestic, commercial or industrial. The rate of per capita consumption, as determined from statistics in such reports, is a composite made up of all varieties of use, and throws out little light upon any one type. The only available sources for such data are reports of special tests. With the increased tendency toward zoning, as stimulated both by city and regional planning programs, more detailed information is coming to be in greater demand. The following specific data for consumption in California cities have been obtained from various sources, and will be presented in the hope that it will stimulate the more systematic collection and publication of such information. In addition to other uses, such data would be very valuable in distribution system design.

Domestic use includes that necessary for human needs, such as drinking, cooking and washing. To this should be added the water used for irrigation of gardens and lawns, where such is necessitated by local climatic conditions. Table I indicates the amount of water delivered for this purpose, as indicated by various tests.

The influence of lawns and gardens in increasing the rate of domestic consumption is quite apparent. First-class residential areas, for example, with large improved estates consume three times the quantity of water used on areas where the demand is limited to strictly human needs. It is to be noted in using these data that, with the possible exception of the area served by the Belvedere Water Corporation, the data apply to fully built-up districts. The service area as reported for a whole city, on the other hand, would ordinarily include isolated vacant lots and other small non-consuming areas.

"Commercial Use" Defined

The term "commercial use" as generally applied, includes not only the strictly commercial use of water in hotels, stores, office buildings and apartment houses, but also industrial use by manufacturing plants, railroads, sugar refineries, laundries, etc. Commercial use is usually small relative to total consumption, and is constant in amount.

Industrial use, however, may be very large in amount and varies with business conditions and the relative cost of water from the public system and from privately developed sources. Considered from the standpoint of areas, the two services seldom overlap. With haphazard growth, commercial and industrial plants are seldom to be found mingled, and modern zoning practice tends to emphasize the separation. For purposes of

estimating future water requirements, it has been found very useful to have the two services considered separately, and they will be hereafter so considered in this paper.

The amount of water used in commercial service, although a small proportion of total consumption, is large when expressed as depth upon the area to which the water is actually delivered. This is illustrated by a test made by the Bureau of Waterworks and Supply of the City of Los Angeles for the consumption in the congested business district bounded as follows:

Hill St. from First to Fifth St., Fifth St. to Grand Ave., Grand Ave. to Sixth, Sixth St. to Figueroa, Figueroa St. to Ninth, Ninth St. to Los Angeles, Los Angeles St. to First, and First St. to Hill. The water delivered to this area of 324 acres in September, 1923, was equivalent to a depth of 2.16 feet. As the rate of delivery to this area is practically constant throughout the year, the annual depth may be considered as 24.36 feet. Spread over the whole city service area this amounts to but 0.10 feet in depth, as compared with the total annual depth for all purposes of 1.74 feet.

Good Field for Study

The amount delivered for industrial purposes in the typical area of 183 acres bounded by Seventh, Sacramento and Alameda streets, and Los Angeles River, was also measured. This area received during the period July 1, 1923 to June 30, 1924, a depth of 1.67 feet of water. This quantity is very small in comparison with the amount of water consumed in the industrial districts of many eastern manufacturing centers. For the larger American cities, the water used in industrial purposes, if spread over the whole city service area, exceeds 1.50 feet.

As industrial plants occupy a minor portion (less than one-fourth) of even the most distinctively industrial cities, it is to be inferred that the annual depth consumed on the area actually devoted to industrial use may be as great as 5 or 6 feet, and may even exceed this figure in the case of special industries using large quantities of water for washing processes. Data are very meagre on this subject, and, with the prospective industrial growth in many western cities, special effort to obtain such information for different types of industry would be well worth while.

Water for Irrigation

It frequently occurs in western cities that irrigated areas are included within the municipal boundaries. Such lands may either be temporarily used for commercial agriculture in the raising of berries, garden truck, or flowers, or may be more permanently devoted to residential or recreational purposes. Golf courses and public parks and playgrounds may be included within the latter. Often as a city expands it encroaches upon irrigated farm land devoted to the growing of orchards or general crops. The question thus arises in waterworks practice as to the quantity of water used by such land under irrigation, as compared with the needs of the same land under suburban or urban conditions. The subject of the use of water in irrigation is beyond the scope of this paper, but for comparative purposes certain general data may not be out of order.

TABLE I
DEPTH OF WATER IN DOMESTIC USE

Character of domestic use	City	Authority	Depth of water used in feet per annum

Third class residential—small lots, few gardens	Belvedere, Laguna and San Antonio Twp. adjacent to N. E. Limits City of Los Angeles	Belvedere Water Corporation	0.68

Factors Governing Consumption

The amount of water required in irrigation depends upon many factors, among which may be mentioned climatic conditions, including temperature and precipitation, soils and crops. For lands already under irrigation the stage of economic development of the region and the character of the people are important factors. Recent comprehensive studies made by the State Engineer show that in California the amount of water actually used in various parts of the state for irrigation of general crops varies in depth from 1.14 feet to 3.88 feet per annum, and that a corresponding desirable duty would vary from 1.25 feet to 3.00 feet.* These figures are for water delivered to the land, and do not include the large losses in transmission often amounting to as much again as that delivered.

The following table compiled from the State Engineer's report gives the average measured use and desirable duty of water in the vicinity of the larger cities of California.

TABLE II
Average Measured Use and Duty of Water in Vicinity of Large Cities of California

City	Measured Use Depth in Feet	Desirable Use (Duty) Depth in Feet
San Diego	1.26	1.25
Los Angeles	1.62	1.75
Bakersfield	2.24	2.00
Fresno	2.24	2.00
Stockton	2.24	2.00
Sacramento	3.88	2.25
Santa Barbara	2.43	1.5
Santa Cruz	1.42	1.5
Monterey	1.82	1.75
San Jose	1.42	1.50
San Francisco	1.42	1.50
East Bay Cities	1.42	1.50
Eureka	1.52	1.25

It is to be recognized, however, that the above values represent broad averages and that considerable local variation from them is to be expected. Taking up more detailed data, the irrigation use for general crops in the San Fernando Valley within the boundary of the City of Los Angeles, as served from the city's irrigation system, is reported as follows by the Bureau of Waterworks and Supply:

TABLE III
USE OF WATER FOR IRRIGATION IN SAN FERNANDO VALLEY, CITY OF LOS ANGELES, CALIF.

Year	Recorded Gross Average Use	Net crop Average Use	Recorded Gross Duty Depth in Feet	Net Crop Duty Depth in Feet
1919	[illegible]		1.06	
1920	[illegible]		1.09	
1921	63,300	33,000	1.20	1.18
1922	[illegible]		1.30	
1923	[illegible]	52,810	1.43	1.60
1924	[illegible]	51,723	1.02	1.20
Average			1.18	1.39

More than half the acreage in the San Fernando is planted to crops requiring but little irrigation, such as beans, walnuts, etc. Where a considerable pro

STORAGE & DISTRIBUTION

Cooperation of Utilities Is Doing Much to Solve the Corrosion Problem

Better Rail Bonding, Use of Larger Rails and More Substations Have Reduced Loss from Electrolysis

By E. B. STEWART

Electrolysis Engineer, East Bay Water Company, Oakland, California

Editor's Note: This is the second and concluding installment of a paper on corrosion problems of a water supply system and methods of protection, read by Mr. Stewart before the recent annual convention of the California Section of the American Water Works Association at San Diego, Calif. The first part, printed in the November number, concerned soil corrosion, whereas part two discusses corrosion from externally applied electric currents and preventive measures.

CORROSION from stray current is of special importance in cities where buried metallic conductors come in more or less close association with electric railway systems. The chief factors involved in dealing with stray current electrolysis comprise the testing for, and the control of, stray currents responsible for the damage.

The majority of the street railways of the country are operated on the single trolley system using the rails to return the current back to the power station. The total current, however, will not return to the power station by the rails; a part of the current will shunt from the rails to earth in the negative area and find its way to nearby networks of metallic underground structures and flow on them in a general direction toward the substation. As the station is approached, the current tends to leave the structures to earth and return to the rails. Corrosion will take place where these currents leave the pipes to earth.

Another Source of Damage

Experience has shown that stray currents also leave the pipe in the negative zone at remote distances from the ends of the car lines, a condition which is somewhat contrary to the usual explanation of the flow of stray currents. This condition is made possible by two separate tracks leading from the same power house and laid out in such a way that the return of one line is almost without loss of potential, while the other has considerable loss. In this case part of the current will leak across through the earth to the track which is without loss of potential. These currents will accumulate on the pipes running in the same general direction and very often cause rapid corrosion.

An example of corrosion from stray current in accordance with these conditions was found at a point one mile distant from the end of the nearest railway line. Earth current measurements showed an average current of six milliamperes leaking to earth from every square foot of pipe. This is an unusually high leakage current, when it is considered that leakage values below .5 of a milliampere per square foot are considered safe.

Preventive Measures

The magnitude of stray currents is determined by the design, construction, maintenance and operation of the railway system. In the effort to eliminate the corrosion from stray railway current, the most logical procedure is to attack the trouble at its source, the production of the stray currents.

An analysis of the power distribution and the operation of the railway is the most essential factor to consider when making electrolysis surveys.

The question of electrolysis has been very actively studied for a number of years by the "American Committee on Electrolysis," which was formed from representatives of the various public utility associations whose interests were affected. Most members of this association are probably familiar with the report of the committee issued in 1921. This report represents the unanimous opinion of the representatives of all the different interests involved.

A matter of particular concern is the study and development of railway distribution. Considerable progress has been made in recent years in the development of automatic, semi-automatic and remote control substations, and these are now being used on both city and interurban lines. The economic operation of such substations makes possible a greater number of feeding points than can economically be supplied through manually operated stations. The increase in the number of substations will obviously reduce the feeding distances, and effect a saving in distribution copper, and a saving in line and return losses. The general effect is the reduction of track voltage drops; thereby reducing the leakage of stray current into the earth.

Important Development

This is a very important development in railway operation for the protection of damage to pipes from electrolysis, as the same factors that determine economy of railway operation also control the leakage of stray currents to earth.

Within the last year, four additional substations have been added to the local railway system within the territory affecting our piping system and recent surveys show that such measures have materially reduced stray currents in the piping systems.

The principal measures used by this company to eliminate or reduce corrosion from stray current are:

1. Electrical drainage.
2. Insulating joints.
3. Electrical connections between pipes in close association.

Electrical Drainage

Electrical drainage is used to drain enough current to make the pipes negative to the earth in the vicinity of negative feeder connections. While electrical drainage is not considered good practice by many engineers, nevertheless, under certain conditions, it appears to be the best temporary expedient consistent with economy. Where large mains are already in place, it seems logical to apply a limited amount of drainage until such time as remedial measures can be applied to the railway system. Electrical drainage is applied in cooperation with other utilities through committee activites which will be discussed later in this paper.

Where drainage systems are in use, very careful surveys and inspections must be made at frequent intervals if adequate protection is to be realized, as changes and extensions to either railway or underground systems will establish added points of hazard.

Care must be taken to avoid unequal drainage between pipes that are in close association. The drainage of one system of pipes will, of course, lower its potential with respect to the neighboring pipes tending to injure the latter. This in turn calls for drainage of the

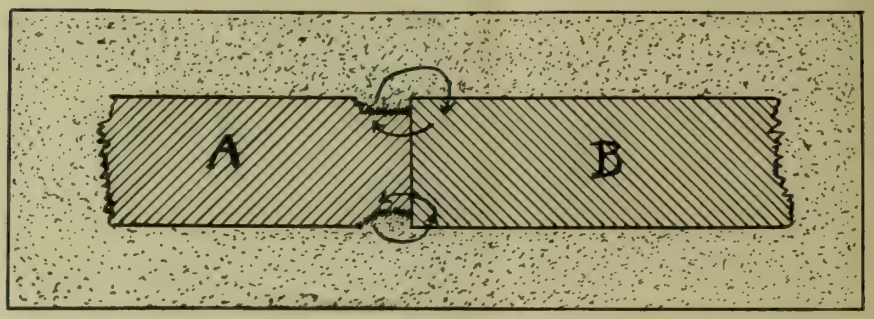

Diagram illustrating galvanic action between two dissimilar metals in contact buried in soils. A. Electropositive metal which is corroded. B. Electronegative metal which is protected against corrosion at the expense of the electropositive metal.

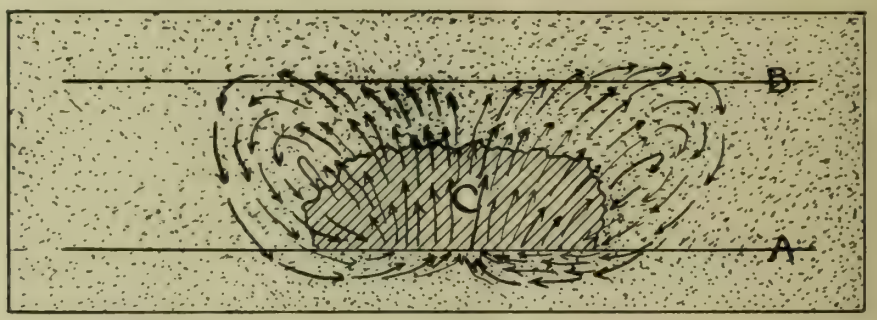

Diagram illustrating how corrosion is accelerated by two pipes in close association in the earth. Pipe "B" acts as a conducting medium to complete a galvanic circuit from the area "C" of high concentration.

injured system which may in turn damage the first or other structures and consequently a system of competitive drainage is established.

Overdrainage of cable systems is very often a hazard to pipe structures. Pipes as a rule are much closer to cable conduits in the ground than they are to rails. In many cases, the pipes are resting directly against the conduit. Under such conditions where both metals are in wet soil, it is possible for large leakage currents to flow and cause damage to the main or service pipe. In one particular instance, overdrainage of cable systems caused serious damage to one of our transmission mains on a street where no electric railway tracks exist. This condition brings out the fact that potential measurements between pipes and cables should not as a rule be confined to streets having railway tracks.

Insulating Joints

Insulating joints are used in new pipe lines and some existing lines in negative and neutral zones with particular reference to those points where it is expected that large transverse currents are flowing between parallel rails due to unusually high voltage drops between them, or where it is expected that currents will be transmitted to and discharged from the pipes in soils of low electrical resistance. In the insulated sections, the service pipes are prevented from making electrical contact with other piping systems by the use of insulating joints at the meters. Without insulating joints in the service pipe, stray current could enter from the other piping systems through gas water heaters and other appliances with which it comes in contact and injury would result to both the service and the section of the main to which it connects. It is often necessary to install insulating joints on cross mains which connect the insulated sections.

We have found from laboratory studies, together with studies in the field under working conditions, that cement used as an insulating medium offers the highest electrical resistance to the flow of stray current, and when joints are placed at regular intervals of approximately 100 feet, the current flow on the pipe lines is reduced to relatively small values. Resistance measurements of a number of insulating joints that were in service for approximately three years, showed an average electrical resistance of .6 ohms in soils having a resistance below 1000 ohms per cubic centimeter. In many cases the resistance of an insulating joint is greater than the resistance of 400,000 feet of pipe.

Objection Answered

The principal objection that has been raised to the use of insulating joints is that corrosion is apt to occur on the positive side of the joint. During the last four years we have engaged in regular tests and inspections for joint corrosion, and to date no corrosion from this cause has been located. The reason why such installations might fail to protect the

pipes in many instances is the too infrequent use of insulating joints especially if the pipe line is laid parallel with high potential gradients in the earth.

For example, in a case, where the difference of potential in the earth is, say, ten volts per 1000 feet, and a pipe line is located in a direction approximately parallel to the electromotive force, heavy currents will, as a rule, be picked up by the pipe, and if this is discharged into the earth, serious damage will, of course, result. If the continuity of the pipe is broken up by inserting insulating joints, then practically all of the potential drop would be concentrated at the joints. For instance, if two insulating joints are inserted in a pipe 1000 feet in length, the drop across each joint will be approximately five volts.

Since the leakage path around such joints is usually very short, it is evident that high voltage potentials will produce a correspondingly high current density across this short distance in soils of low electrical resistance, and as a consequence, sufficient currents will flow around the joints to destroy them within a comparatively short time. It is evident that in order to prevent this, a sufficient number of insulating joints must be used so as to reduce the current density around the joints to a practical minimum. In other words, the frequency with which insulating joints may be placed to secure adequate protection against electrolysis is determined by two factors, namely, potential gradients in the earth and electrical resistance of the soil.

To illustrate a practical example of the effectiveness of insulating joints, a sixteen-inch non-insulated steel pipe having been destroyed beyond repairs after less than three years' service, was renewed with the same size and kind of pipe with insulating joints placed at regular intervals of 100 feet. This pipe has been in service a little more than four years, and to date, it has not suffered damage from electrolysis, although subjected to the same stray current conditions.

Earth Current Meter

The most difficult part of an electrolysis survey, perhaps, consists in drawing proper conclusions. No one set of measurements will suffice as a basis. While potential measurements represent the tendency to produce stray currents, the currents which cause the damage are determined as well by the restivity of the soil, which varies over wide limits from one part of the city to another. Currents flowing in the pipes will be affected by the relative location of the pipes and the rails in the streets. Services or mains

METERS & METERING

Electrically Operated Flow Meters Show Trend Toward Efficiency

WITH the great advancement which has taken place in engineering practice, realization of the importance of making systematic and accurate measurements of the conditions and quantities involved has grown rapidly. At the same time, the desirability of locating the meters at points of greatest convenience to the users is more keenly appreciated today than ever before.

An example of this trend is supplied by the popularity of flow meters of the electically operated type by the use of which an indicator may be located in clear view of the boiler fireman as a guide in firing, with the recorder and integrator placed at a convenient point among a group of recording instruments.

No Mechanical Motion

Also, from another point of view, electrical operation is especially advantageous for flow meters, since it affords a means of producing external indications and records of conditions existing inside of a high pressure steam or water pipe, without transmission of mechanical motion—as for instance, by means of a rotating shaft, passing through a pressure-tight packing gland, which of course would be essential and would necessarily cause serious friction losses.

Naturally, however, when electrical means are introduced to avoid the objectionable features of a mechanically-operated instrument, other undesirable features are likely to be introduced unless careful planning is applied to all phases of the question.

Because of these considerations, the new Brown electrically operated flow meter would seem to deserve the special attention of all engineers interested in flow measurement, since by a novel, but thoroughly practical utilization of a well-known electrical principle, the design of the Brown electric flow meter at one stroke avoids all electrical as well as mechanical difficulties.

Six Features Listed

Among the characteristics of this new line of instruments are the following features:

1. The readings of the instrument are fundamentally independent of the value of the voltage impressed upon the electrical system. The instrument reads correctly, while operating on varying line voltages without the use of either voltage regulators or compensators.

2. The electrical circuits at the manometer, indicator and recorder consist simply of stationary, divided, inductance coils. These have only three connections which are permanently made at the time of installation. There are no make-and-break contacts.

3. In the manometer, or meter body, all electrical windings and connections are entirely external to the pressure chamber.

Electric Clock Control

4. The integrator is a mechanical device operated by the electric clock which is available for operating the integrator at all rates of flow, making possible the use of the most easily-read type of 5-figure counter for the integrator.

5. A pen operated by the action of the integrator mechanism makes a record at the outer edge of the chart each time the integrator mechanism increases the counter reading by one unit. Each tenth mark is distinguishable from the intermediate marks in order to facilitate counting when it is desirable to determine the total flow for a day or during any hours of the day, without having to watch the counter.

Compact Arrangement

6. The entire integrator mechanism with its individual recording pen is so simple and compact that it can be mounted in the standard recorder case along with the recording mechanism, thus avoiding the necessity of a separate integrator case.

The simple inductance bridge principle upon which all of these instruments operate, their freedom from troubles obviated by electrical connections that are permanent and external to the pressure chamber, their independence of voltage fluctuation, their automatic recording planimeters, the adaptability with which their manometers handle various ranges, their easy reading 5-figure integrating counters, the compactness of their operating units—the advantages of all of these va-

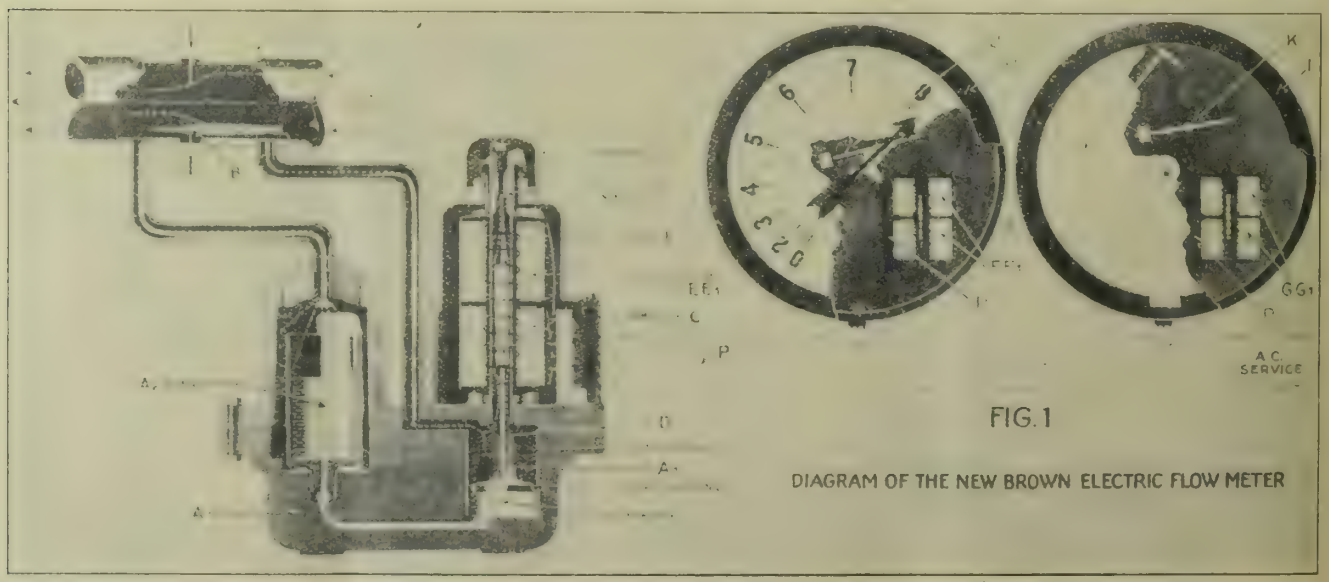

FIG. 1

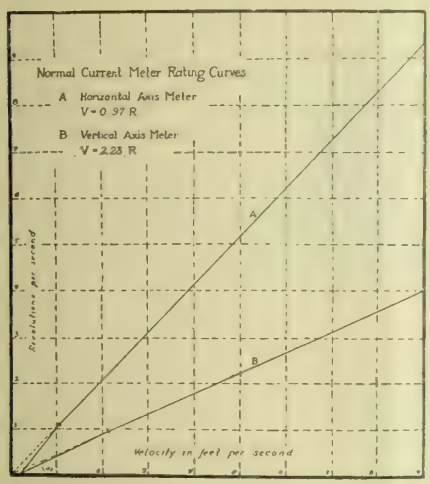
DIAGRAM OF THE NEW BROWN ELECTRIC FLOW METER

rious features, the manufacturer asserts, make this new flow meter especially desirable for measuring the flow of steam, water, gas, air and other fluids, and of exceptional interest to all power plant and industrial engineers and officials concerned with such measurements.

Current Meter Notes

A recent survey of current meter literature revealed many references to rating



Normal Current Meter Rating Curves
A Horizontal Axis Meter
V = 0.97 R
B Vertical Axis Meter
V = 2.23 R
Revolutions per second
Velocity in feet per second

TYPICAL CURRENT METER RATING CURVES

curves in connection with developing the rating equations. No mention was made of the importance of the rating curve as a source of information concerning the efficiency, reliability and friction of meters.

Since necessity and desire for better and more economical work have increased the interest in current meters, it may be opportune to call attention to the benefits obtainable from an inspection of the meters and its rating curve.

The current meter rating curve is the graphic record of meter actions under definitely known water and operating conditions.

* * *

An efficient meter has a normal rating curve consisting of two sections whose merging point designates that velocity at which reliable meter work may be expected, as far as the meter itself is concerned. At low velocities, the opposing or negative forces such as friction, inertia, eddies and others are relatively strong; they interfere with regular meter actions. The meter indications under such circumstances can not be trusted.

The efficiency gauge for any meter is the distance of the merging point of the curve sections from the zero line, expressed in velocity per second. The shorter that distance the better the meter.

CATALOG and ADVISORY SERVICE ON REQUEST

A sluggish meter has a low sloped curve which indicates considerable stream disturbances. Such meter, if of large size, is laborious to operate and its indications are apt to be incorrect because the presence of the meter is materially changing the original stream flow to ascertain which is the primary object.

An active meter gives a rating curve of steep slope, suggesting high quality of meter work especially if the meter is small in size and in form stream-line. The original stream flow is but little disturbed by such meter and the meter operation requires but nominal manual effort.

* * *

Current meters may be classified by their individual rating curves. A normal curve is typical for all meters whose rotors are unprotected and unobstructedly exposed to the stream forces. It consists of a high and a low velocity section, the former being identical with the ideal curve (that curve obtained by rating an imaginary, perfectly frictionless meter, operated under ideal conditions). The normal curve permits the application of the ideal curve as a reference line, thus making it possible to discriminate between correct and faulty rating points.

Since not all rating stations are provided with indicating devices to give distance and time of meter travel and the meter revolutions automatically, it is more than likely that some of the rating points are erroneous.

It would be wrong to place such faulty points in line to determine the rating curve and the equation. All faulty points are exposed by the ideal curve, when it is applied as reference line.

* * *

Some meters are surrounded by frames and rotor protections, which invariably interfere with the free approach of the stream filaments and encourage eddy formations. Their rating curves are broken line curves and do not permit reference to the ideal curve. Their rotor action is the result of artificial water conditions created by a multitude of eddies. They do not indicate the original stream flow. Meters of this type are reliable only when stream conditions are perfectly identical to those under which they were rated.

* * *

A current meter rating curve does not indicate accuracy of meter work, it shows, however, the efficiency of the meter and gives that stream velocity at which the meter is expected to act reliably, providing the stream and operating conditions are favorable to good meter work. To determine this is left to to the ingenuity of the operator.

Frank J. Kimball Passes

Frank J. Kimball, for fifteen years president of the Frank J. Kimball Company, Los Angeles, passed away November 4 at his home in Los Angeles, following a chronic ailment of some years standing.

Active until a few days before his death, this well-known engineer and manufacturer had reached only the age of 52.

Born in Meridian, Mississippi, Mr. Kimball came to California in 1889 and immediately entered the field of engineering, particularly that branch relating to underground water supply.

F. J. Kimball

In the fifteen years of Mr. Kimball's continuous service as president of the company founded by him, he became widely known as an authority on water supply. He was an inventor of note, as is evidenced by the successful business he developed in the Kimball direct flow turbine pump, now used extensively wherever water is required from underground sources.

Mr. Kimball was a member of many engineering societies, and tendered his advice and support on many engineering projects for the country at large.

Engineering Details of Dam

(Continued from Page 13)

northwest corner of the property to be irrigated. Within the property, it runs about 15 miles farther, gradually narrowing from a capacity of 500 to 20 second feet at the southerly end.

At each section line, laterals are taken off, running east and carrying from 100 second feet down to 10 and finally 7.5 second feet in the sublaterals. Each sublateral runs to the high point of the quarter section which it serves.

The dam and diversion system were designed by C. E. Griggs, chief engineer of the district. They were then checked and approved a second time by Stone and Webster of Boston, before submission to the experts of the bonding houses which handled the securities.

Preliminary work in the development of an irrigation project near Needles, California, has begun with the shipping of casing and well supplies by G. P. Mohler to his holdings, and the sinking of a well on the land of H. K. LeClair. Work on other wells is to be begun shortly. It has been estimated that each of the wells will supply water enough for irrigating 100 acres of alfalfa.

The Progress of Irrigation

(*Continued from Page 10*)

$230,000 in 1935. This project under the program will be completed in 1935.

On the Belle Fourche, South Dakota, project $1,000,000 will be divided as follows: $125,000 in 1928, $250,000 in 1929, $250,000 in 1930, $250,000 in 1931, and $125,000 in 1932. Under the program this project will be completed in 1932.

A total of $12,400,000 will be spent to complete Echo reservoir and Weber Provo canal and other divisions distributed as follows: $1,240,000 in 1928, $1,000,000 in 1929, $760,000 in 1930, $1,400,000 in 1934, $2,000,000 in 1935, $2,000,000 in 1936, and $3,000,000 in 1937. At the end of the ten-year program this project will not be completed and it will be necessary to expend an additional $1,000,000 thereafter to complete it.

At Okanogan, Washington, $320,000 will be used to line laterals and complete pumping plant and the entire amount to be expended in 1929.

At Yakima, Washington, $25,579,000 has been apportioned for storage at Cle Elum reservoir and to complete construction of Roza, Kennewick, and Kittitas divisions. The expenditures on this project include $2,000,000 in 1928, $1,500,000 in 1929, $1,500,000 in 1930, $1,700,000 in 1931, $2,000,000 in 1932, $2,000,000 in 1933, $3,011,000 in 1934, $2,500,000 in 1935, $2,500,000 in 1936, and $2,500,000 in 1937. At the end of 1937 this project will not be entirely finished and an expenditure of $4,368,000 will be required thereafter.

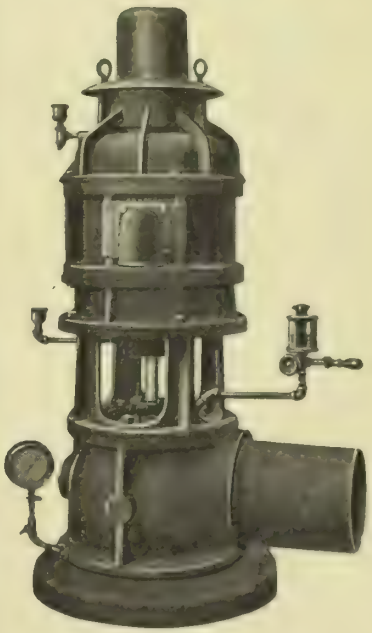
A total of $5,195,000 will be spent to complete the Riverton, Wyo., project as follows: $600,000 in 1929, $600,000 in 1930, $500,000 in 1935, $2,000,000 in 1936 and $1,495,000 in 1937. Under the program this project will be completed in 1937.

The sum of $5,193,000 has been proposed for drainage on Garland division and distribution and drainage on Willwood division and completion of Heart Mountain division, Shoshone, Wyo., project divided as follows: $150,000 in 1928, $340,000 in 1929, $248,000 in 1930, $1,000,000 in 1935, $1,000,000 in 1936, $1,000,000 in 1937. Under the program this project will not be completed at the end of ten years and expenditures thereafter amounting to $1,455,000 will be necessary.

Watson Water Company of Romoland, Riverside County, has applied to the California Railroad Commission for a certificate of public convenience and necessity for the distribution of water in that district and for the establishment of rates for such service.

Layne & Bowler
Turbine Centrifugal Pumps

42 years of pump leadership



For two generations pump building and water development have been the life work of Layne & Bowler officials. As pioneers of deep well water development we have, during this long period of time, tried and tested every conceivable type of pump—and by the process of elimination have evolved a pump that is the most dependable, efficient type possible to obtain. Our forty-two years of experience cannot be duplicated by any other concern—and you derive the benefits of this mature knowledge without extra cost. Layne & Bowler Pumps have won their reputation mainly on their economy of operation. Let the World's largest water developers solve your pumping problems.

WATER PURIFICATION

Southern Pacific Railroad's Experience With the Zeolite Treatment

By C. W. STURDEVANT

Assistant Engineer of Tests, Southern Pacific Company, San Francisco

DURING the past twelve to fifteen years considerable attention has been paid to the zeolite or "base exchange" method of water softening, especially for use in connection with laundries and stationary boilers, but practically no railroad, with the exception of the Southern Pacific Company, has made use of this treatment in connection with locomotive boilers.

The principle of zeolite treatment is that of base exchange, making use of base-exchange silicates possessing those properties by which they may combine with either the base sodium or the bases calcium or magnesium.

When regenerated, that is, ready to soften water, the mineral is possessed of a supply of base sodium in exchangeable form. During the softening run, this base sodium is replaced by the calcium and magnesium bases of the hard water.

When the supply of the base sodium is exhausted, that is, when the mineral has become possessed of its capacity of the calcium and magnesium bases, this softening action ceases. At this stage of the process the mineral is ready for regeneration, during which it is treated with a solution of sodium chloride (common salt). This salt is rather cheap and readily obtainable.

Regeneration Reverses Action

During the regeneration, the exchange of bases is exactly the reverse of that which takes place while softening water. At this time the base sodium of the salt is taken up by the mineral which gives up its load of the calcium and magnesium bases in exchange therefor. These hardening bases combine with the chloride of the salt solution which, during the regeneration, or salt brine flushing, is changed from sodium chloride to calcium chloride or magnesium chloride. These chlorides, being soluble, cause no sludge and are therefore flushed off through any convenient drain.

With the rapid-rate mineral now used by most of the manufacturers of zeolite water softeners, the time required for reconditioning of the zeolite mineral has been reduced to fifteen or twenty minutes. The two processes, softening water and then regenerating with salt brine, are repeated alternately with practically no loss to the mineral itself, during years of service.

This treatment is entirely independent of the actual water softening which does not take place while regeneration is going on; hence what excess of salt solution is required is simply washed away to the drain with the chloride of calcium and magnesium. The excess is never carried away in the treated or soft water.

During the base-exchange process of softening water, the exchange of bases, sodium for calcium and magnesium, is in the exact relation of the combining powers of these elements; therefore, overtreatment is impossible.

Factors Affecting Plant Size

The amount of zeolite mineral required is also proportional to the amount of water desired to treat between reconditioning periods coupled together with the incrusting content of the untreated water, as the converting power of the natural zeolite mineral, or green sand, is approximately 40 grains to the pound of mineral, under most favorable conditions, to 30 grains under ordinary operating conditions; consequently the size of the plant must have a certain amount of engineering in order to fit in with the variable local conditions.

The waters which are being treated on the Southern Pacific Company's lines are, by analysis, very similar to those found in other parts of the states and vary, naturally, as do waters elsewhere. At the present time, we are treating water varying from 11 grains of incrusting matter and 5.48 grains of soluble matter per gallon up to 33.94 grains of incrusting matter and 8.69 grains of soluble matter per gallon, and in one case, that of the El Centro, California, city supply, from the Colorado river, carrying 26.7 grains of incrusting matter as well as 20.58 grains of soluble salts.

In all cases the total incrusting matter is converted to soluble matter through the zeolite method of treatment, producing a zero-hardness water, with the exception of the silica, alumina and oxide of iron, which in ordinary cases range from one-half of one grain to say three grains per gallon. This, however, does no harm whatever nor does it form any scale in the absence of a binder, such as the calcium and magnesium carbonate and sulphate, which, as above stated, have been converted to sodium carbonate and sulphate.

However, this soluble matter produced by the treatment and added to the soluble matter originally contained in the untreated water, builds up a total of the combined soluble and insoluble matter, making what is ordinarily termed light water which always been feared due to the belief that much foaming and priming might result.

Again, fear of corrosion or pitting might be encountered.

Caustic Embrittlement Not a Factor

Also, as a result of said treatment, some have entertained the belief that caustic embrittlement might result. It is true that in some cases, where our locomotive boilers are badly scaled up, we do have a little trouble from foaming immediately after starting a zeolite plant. This is due to the fact that the salt water has a dissolving effect upon the old scale, producing a heavy sludge within the boiler and if not blown out regularly and rather often, foaming will result. However, if a reasonable amount of care is exercised in the handling of the blow-off cock, together with proper washing of the boiler, very little, if any trouble is encountered, and after a reasonably short time, most of the old scale will have disappeared and then such light water condition disappears.

So far as corrosion and pitting are concerned, we have paid particular attention to this and have even suspended pieces of new boiler plate, boiler tubes, steel wire, etc., in the boilers as close to the firesheet as possible and have left them in this position for from six months to a year, making inspections and tests after such time only to find material in original condition. We appreciate that even these tests are not the same or as severe as if the test pieces were a part of the firesheet or tube and therefor do not carry a convincing argument. However, we are still mindful of the possibility of above-mentioned after effects and are ever on the alert. So far, we have seen nothing to sustain the corrosion or pitting theory.

It is not my intention to claim that

Chlorination

Manual Control Solution Feed Chlorinator - Type MSP

A new rugged apparatus in which the Chlorine is measured under a Vacuum

has become standard practice for the sterilization of water, —the sanitation of swimming pools,—the disinfection of sewage,—the elimination of noxious odors,—and for many other purposes,—largely because of the accuracy and reliability of W&T Chlorine Control Apparatus.

¶ Chlorination of drinking water is not only unsurpassed community health insurance but it is downright good business insurance,—in view of the recent tendency of the Courts* to award damages to persons stricken with intestinal disease caused by polluted water.

the zeolite treatment is a cure-all for all waters. There is no doubt in my mind but that in a water excessively high in temporary hardness, calcium and magnesium carbonate, this hardness should first be reduced or precipitated by means of the lime treatment before passing the water through the zeolite plant, thus reducing the total soluble or alkali content after treatment to a minimum. However, this company has not, as yet, had to resort to this pre-treatment, due to the fact that as yet we are not attempting to treat, with the zeolite method, water excessively high in temporary hardness.

Bad Water Causes Epidemic

What is said by state health officials to be the most serious outbreak of typhoid fever which has occurred in any similar area in the state within the recent years broke out some weeks ago in Akron, New York, more than 200 persons out of a population of 2,000 having been ill with the disease. The State Health Department assigned two physicians and 10 health department nurses, the Erie County chapter of the Red Cross also sent ten nurses, and fifty private nurses have been employed for these cases.

There is said to be no question but that the epidemic is due to the water supply, which was known to be polluted but the use of which was continued, although an effort had been made to eliminate danger by the use of chlorination in 1920. The State Health Department had advised a safer supply and the local Chamber of Commerce had seconded this advice, but nothing came of it further than the installing of a chlorinating apparatus. During October the chlorinating apparatus had been out of order and its use was discontinued for several days and it is believed that most of the cases were due to the water drunk during that intermission of the chlorine treatment.

P. G. & E. Sells Water Supply Plants to New York Firm

Another wholesale transfer of water service properties was brought about through the recent sale by the Pacific Gas and Electric Company of all its water holdings to the Federal Water Service Corporation of New York, announcement of which was made on December 9. It was also stated that the Federal Corporation had purchased the Port Costa Water Service Corporation, formerly one of the holdings of the McNear estate.

In addition, C. T. Chenery of New York, president of the Federal Corpora-

tion, announced the recent purchase by his company of the water supply companies in Hermosa, Redondo, and Martinez.

Clean Up Field

The campaign of acquisition of Pacific Coast water companies was begun three months ago, it was disclosed, with the purchase by the Federal of the Fresno City Water Corporation, formerly owned by the San Joaquin Light and Power Company. Since that time the New York concern has acquired the independent water companies of Bakersfield, Visalia and Chico.

The water holdings of the Pacific Gas and Electric consisted of the six companies serving Stockton, Oroville, Willows, Redding, Dixon and Livermore. Their purchase will give the Federal 292 miles of water mains throughout the northern and central portions of the State and make it the largest exclusively water corporation in the United States, according to Chenery.

This is in line with the policy announced by the New York concern at its organization six months ago to acquire water property all along the Pacific Coast.

To Handle As One

Subject to the approval of the State Railroad Commission, the Federal plans to merge the fourteen California companies, the gross income of which is estimated to be in excess of $1,500,000 annually, into one operating organization to be known as the California Water Service Corporation, Chenery announced, which will be a subsidiary of the parent company in New York.

The Federal corporation already has acquired extensive water service holdings in the East, which have been similarly merged under the names of Union Water Service Corporation, West Virginia Water Service Corporation and New York Water Service Corporation.

Terms Not Stated

Prices and terms of the transfer of the Pacific Gas and Electric Company's water companies were not disclosed, but that several millions will change hands as a result of the deal is conceded.

C. B. Jackson, formerly general manager of the Fresno City Water Corporation, will be vice president and general manager of the California concern, Chenery said, while E. B. Walthall of Fresno will act as its secretary-treasurer. E. K. Barnum will be chief engineer.

McCutcheon, Olney, Mannon and Greene of San Francisco are counsel for the Federal Water Service Corporation in California and have handled the legal proceedings in connection with the transfers of the various water properties.

SEWAGE DISPOSAL

Activated Sludge Processes and Their Recent Development in U. S. Cities

Pasadena, Lodi, Pomona and Folsom Prison Are Only California Localities With Activated Sludge Plants

By WALTER C. ROBERTS

*Director of the Pacific Engineering Laboratory of San Francisco**

THE early history of the activated sludge method of sewage disposal credits two American investigators, Black and Phelps, with doing the first experimental work on the aeration of sewage in 1910. In 1912 the Massachusetts State Board of Health at Lawrence, Mass., conducted laboratory experiments by aeration of sewage in gallon bottles, and later in a small tank. The chief result of these early experiments was to prove that aeration of sewage had a marked clarifying effect, and to greatly stimulate scientific interest in this method.

Dr. Fowler, in Manchester, England, began experiments in 1913 and was the first to show the real value of mixing previously aerated sludge with fresh sewage. Bartow and Mohlman at the University of Illinois in 1915 conducted somewhat similar experiments. The city of Milwaukee started investigations in 1914 under direction of Hatton and Copeland. The subsequent work at Milwaukee has contributed much to the present knowledge of the activated sludge process.

A few years later the city of Chicago started on a 250-million-dollar sewage disposal program and established a large experimental laboratory. A million-dollar experimental plant was built where the different types of equipment and methods of sewage disposal could be studied under actual working conditions.

England Leads Abroad

Two other cities have carried on extensive experimental work in connection with their activated sludge plants, Indianapolis, Indiana, and Houston, Texas.

Several European countries have carried on investigations on sewage disposal but in the field of activated sludge studies, England has the lead of other foreign countries. The English investigators have evolved new types of plants, three of which will be described later. They also use types of screens and other equipment not seen in this country. The cities of Manchester, Birmingham and Sheffield have conducted the most extensive investigations.

In Canada, particularly in the Province of Ontario, there have been several installations of activated sludge plants, mostly in small cities. These plants are reported as operating successfully, but there is a scarcity of data on their efficiency and operation costs that makes comparison with other plants difficult.

In California, the city of Pasadena, together with adjoining territory, built an activated sludge plant which was largely modeled after the Milwaukee plant. Lodi has an activated sludge plant of a similar type to the Pasadena plant. The principal difference is the method of sludge disposal. Another plant has recently been constructed at Pomona. The only other plant in operation in California is at the Folsom Prison.

Design Discussed

The U. S. Public Health Service has just completed a plant at the Grand Canyon, which is a very complete small plant. After filtering and chlorinating, the effluent meets drinking water standards.

Taking up now the different types of construction, we find that the usual design for activated sludge plants consists primarily of four units. First, some method for removing the coarser materials in the sewage; second, aeration tanks; third, a clarifier; and fourth, some arrangement for sludge disposal. Provision is also made for the return of a certain amount of sludge from the clarifier to the raw sewage entering the aeration tank.

The removal of the coarser materials eliminates substances which would require long periods of aeration and gives an influent entering the aeration tank which contains only finely divided substances. This removal is accomplished by the use of bar screens and grit chambers followed by the use either of fine screens or sedimentation basins. Bar screens consist of iron bars placed from a half inch to an inch apart and remove the large solid particles from the sewage. The grit chambers consist of broad channels in which the rate of flow of the sewage is reduced to about one cubic foot per second. These grit chambers follow the bar screens and remove gravel and other heavy solids.

Several Types of Screens

Several types of self cleaning fine screens are in use which will give a satisfactory influent for the aeration tanks. It has been found that rotating cylindrical screens with short beveled slots of not less than one-sixteenth of an inch in width give good results. This type of screen is preferred to a mesh screen. There is a tendency toward the choice of screens with a minimum of mechanical devices. Rotating cylindrical screens are used at Pasadena and Lodi. The use of settling basins for removing coarse solids is gaining favor. These have a smaller operating cost but larger initial cost than screening plants and take care of maximum flow conditions more easily. The use of Imhoff tanks as settling basins provides for the digestion of settleable material and offers an opportunity to return the excess activated sludge there for final digestion and de-watering. Dorr clarifiers are used as settling basins at the new North Side plant at Chicago. An Imhoff tank is to be used at the new Pomona plant.

The period of detention in the settling basins and in the Imhoff tanks is the same and varies with the nature of the sewage. It is usually about an hour.

In the aeration tanks there are two principal methods of maintaining aerobic conditions in the sewage, one by agitation with air and the other by agitation with mechanical devices.

Aeration Tanks Described

The aeration tanks for air agitation are rectangular with wide variations in dimensions, being built from 12-20 feet in width, from 70-300 feet in length and from 7-16 feet in depth. Air agitation is usually accomplished by forcing air under pressure through porous plates laid in rows at the bottoms of the tanks. The compressed air is furnished by power blowers capable of about 10 pounds pressure. The pressure necessary is but little more than sufficient to force the air through the plates. The plates occasionally become partially clogged, requir-

*An address delivered before the League of California Municipalities at their 28th annual convention, August 16, 1926.

ing greater air pressure and may eventually need to be replaced. The air for the blower is filtered through air filters to remove any substances that would clog the plates. There are two general types of aeration tanks, the "ridge and furrow," and the "Manchester or circulating." The ridge and furrow type has the rows of plates perpendicular to the length of the tanks, each row being separated from the next by a ridge. The ridges prevent the settling of the sludge other than over the plates, where it is caught again in the rising current. The area of the porous plates is from one-fifth to one-tenth of the surface area of the liquid. This type of tank is in use at Pasadena and Lodi.

The Manchester or circulating type of tank has the plates arranged only along one longitudinal side of the tank which arrangement, with the aid of sloping baffles at the top and bottom, produces a rotating motion of the liquid. This method requires fewer plates, slightly less air, and mixes the sewage and sludge more thoroughly than in the ridge and furrow type. There is also the advantage of cheaper construction, lower power costs, and cheaper upkeep. The circulating type of tank is used at Manchester, England, Indianapolis, Indiana, and will be used in the huge new North Side plant at Chicago, and in the new Pomona, California, plant. The amount of air required depends on several variable factors, but is usually about 1.5 cubic feet of air per gallon of liquid treated. The Lodi plant has an enviable record in being able to use what is probably the lowest amount of air per gallon of sewage of any plant keeping authentic records. During most of the year the air consumption is reported at from .6 to 1.0 cubic feet of air per gallon of sewage.

The detention period for the sewage in the aeration tanks is about six hours for both the "ridge and furrow" and the Manchester tanks.

Reconditioning Tanks

The sludge which is returned to the incoming sewage, is frequently reaerated or "reconditioned" in separate aeration tanks before it is used. These reconditioning tanks are usually similar in construction to the other aeration tanks. All conveying channels for both fresh and treated sewage are usually built with porous plates in the bottoms to permit a constant aeration and to prevent the settling out of solids which might start septic action.

Experiments with the air diffusion type of plants indicate that oxygen is most rapidly dissolved from the air as the bubbles break on the surface of the tank and dissolves much more slowly as the bubbles rise through the liquid. The

You *Name the* Load
We *Make the* Pipe!

SINCE concrete pipe (as made by Bent) came into its own, engineers question no longer its striking advantages for a great variety of uses. *But*—a concrete pipe installation is either a mediocre or an eminently superior job of work, depending upon who fulfilled the contract.

Many trade names have become hall-marks of tradition, that serve as an unerring guide to discriminating buyers. Today the name "BENT" on a joint of Concrete Pipe marks it as a strictly finely made product. The same care and skill is exercised in its manufacture, and in the laying of the line, as though every future contract depended on *that* job meeting the fullest requirements of specifications—*and more.*

Let us give you a "concrete" demonstration of what we mean by "Bent" Service.

main function of the rising bubbles is therefore to agitate and mix the sewage and the added sludge. It seemed possible that some mechanical method of mixing and surfacing aeration could be found that would be as successful as air diffusion and easier and cheaper to operate. This has resulted in the manufacturing of different devices for this purpose. At least two of these are worthy of description.

A plant at Sheffield, England, circulates the sewage through narrow and comparatively shallow parallel channels arranged like cross baffles. Paddle wheels in each channel give the sewage an undulating motion similar to that seen in the water behind a stern wheel steamer, the wheels also give the liquid the same frothy appearance. The speed of the current is sufficient to prevent settlement and the length of the channels is such that the undulating motion is continuous. This type of tank is claimed to be economical and successful but has not been widely adopted. There is no plant of this type of operation in the United States.

Simplex Type Described

The "Simplex" type of mechanical aerator consists of an upright iron cylinder approximately twelve feet long and two and a half feet in diameter. This is set on legs in the bottom of a hopper bottom tank with about a six-inch clearance, which permits a free circulation of the liquid into the cylinder. Over the cylinder but not attached to it, is a revolving inverted cone about five feet across, the upper side of which is fitted with curved blades on edge. An opening is cut in the inverted apex of the cone the size of the cylinder. The cone is about the level of the liquid and throws it out in a spray drawing it up from the bottom of the tank through the cylinder. When the spray strikes the surface of the liquid, additional agitation is secured. The cone is driven from a power unit by a shaft which can be extended to run a series of aeration units. This type of plant has given satisfactory results experimentally in Chicago, and Decatur, Illinois, and under operating conditions in a small city in Texas, and a unit is to be installed in California this year. The Simplex system has been installed in several British disposal plants and is being installed in a few American cities.

The clarifier following digestion makes it possible to decant the clear liquid and collect the sludge. Plain basins with steep hopper bottoms are used, but flatter bottoms with a mechanical device for scraping or squeegeeing the sludge to the center such as used in the Dorr clarifier, are more com-

(*Continued on Page 52*)

New Post for Stumm

R. A. Stumm, who is well known to the various California public utilities through his connections with the Paraffine Company, Inc., has recently become indentified with the Los Angeles Manufacturing Company of Los Angeles. Mr. Stumm has followed engineering sales work for a great many years, and has formed a host of friends up and down the Pacific Coast, both in the various public utility companies, and in the oil companies.

R. A. Stumm

The Los Angeles Manufacturing Company is one of the few pioneer organizations of Los Angeles, being formed in 1902. It has progressed very steadily in its growth, and today ranks as one of the largest of its kind in Southern California. It specializes in the fabrication of riveted and welded steel pipe for all classes of work including water supply systems and irrigation. Mr. Stumm assumed his duties December 1.

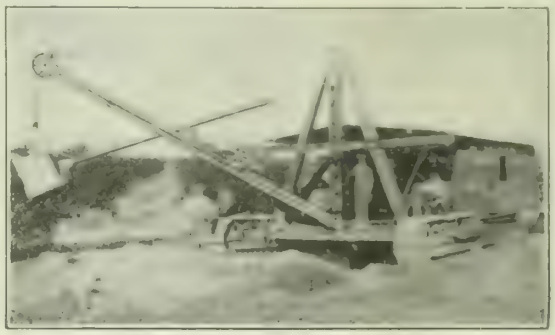
United Concrete Moves to L. A.

The United Concrete Pipe and Construction Company has recently moved its general offices from Merced to Los Angeles, with headquarters in the Chamber of Commerce Building, telephone Westmore 2338. The branch offices of the company at Sacramento, Merced, Ventura, Woodland, and Delhi will still be maintained. The main plant is located at Compton, California.

For Cleanout -- Maintenance -- New Ditches

There's a Bay City for Every Job

BAY CITY Land Dredges span the ditch, can dig any desired slope, and dump waste on both banks. BAY CITIES leave clean, wide berms, and can work up or down streams. One trip over the ditch is enough. The Shovel Type Dipper handles hard material in which other types of buckets cannot make a good showing.



At left—One yard BAY CITY Dredge digging and cleaning ditches in Florida Citrus Groves.

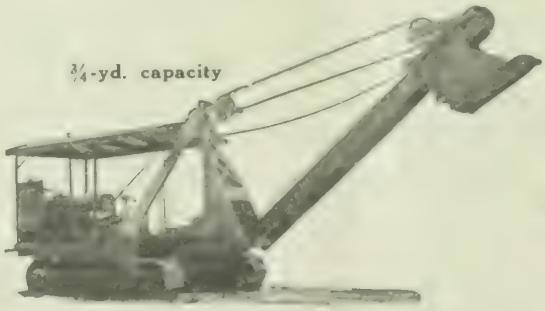
BAY CITY Land Dipper Dredges are built to fit the job. Walking, Crawler, Track or Floating mounting. Easily dismantled, transported and assembled. Capacities ½ to 1½ cubic yards. Oil engine or electric operation.

FOR SMALLER DITCHES — OR PIPE LINE TRENCHES

The BAY CITY 16-B convertible Excavator will handle a wide range of work. Operates Dragline, Trench Shovel, Clamshell or Skimmer. All steel. Shipped assembled. Digs any width or depth up to 20 feet.

STEEL CONSTRUCTION

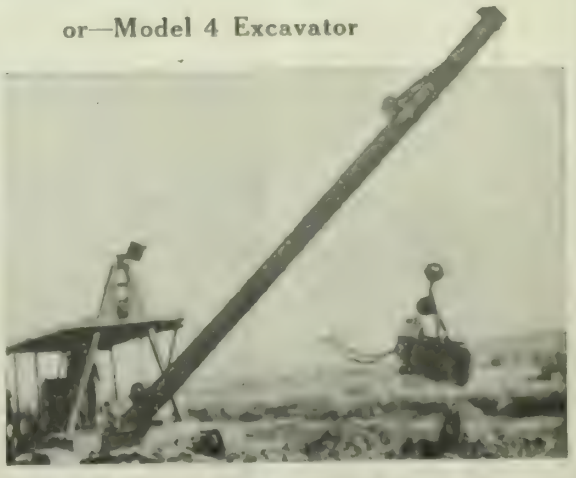
¾-yd. capacity



FULL CRAWLER MOUNTING

or—Model 4 Excavator

BAY CITY Model 4 is a small low-priced convertible, one-man operated Excavator. Fills the gap between hand labor and high priced equipment. Capacity 20 to 40 cubic yards per hour. Gasoline or electric power. A Real Digger economically designed for the small job. Also operates shovel, and clamshell.



One of the Model 4's Owned by Colorado Irrigation Companies. Cleaning Out Canal.

Problems of a Sub-Surface Water Supply

(*Continued from Page 27*)

the Rancho de Kaweah, and conveying it to lands within its boundaries for irrigation and domestic use. Briefly stated, the complaint alleged: That the underground water body in the Rancho de Kaweah is a part of the Kaweah River as the same passes over the Rancho, by lowering this underground body of water which, it was alleged, supported the surface flow.

The stand of the defendant, briefly, was: That there was and is a surplus of water over and above the reasonable needs of all the plaintiffs, allowing for ditch seepage and thorough irrigation of approximately 100,000 acres shown to have been irrigated. All of the principles of law applicable to water and the use thereof were involved in this case. The plaintiffs included in their number riparian owners, overlying land owners and appropriators from natural streams. The right of ditch owners to water lost by seepage from the ditches; the right of overlying land owners to underground waters built up by natural streams; the rights of riparian owners as effected by the "Water Commission Act of 1913," were argued and considered. I should know considerable on this subject after ten years of litigation, and the study of a collection of field data that treats on it from every angle. As a result, but one thought is uppermost in my mind: It is that underground water is and will be for many years to come an important factor in making possible the irrigation of large areas in California.

Two Years Delay

As I said, the complaint was filed July, 1916, and the trial began October, 1917, before Judge Wallace in the Superior Court of Tulare County. It closed after 16 days of argument, in May, 1919. The court gave its opinion in favor of the plaintiffs in July, 1919. The Supreme Court of the State was asked for a writ of prohibition, to prevent the entry of a judgment in accordance with the opinion, on grounds that the judge was an interested party, he having a small lot underlaid with the same body of water that the dispute was about. The writ was granted, and all proceedings to that date were declared invalid. Judge Jones of Nevada was called in, and he made an order requesting the Governor to appoint a Judge outside the county to hear the case. Judge Kinsell of Oakland was appointed, was taken ill after hearing a few motions, and resigned.

Then the Hon. Peter J. Shields of Sacramento was appointed, but on account of pressing business in his court, could not serve. Then Judge William M. Finch was appointed and accepted. The trial of the case proceeded before him for about four weeks, when he was offered a seat on the District Court of Appeals, Third Appellate District. This he accepted and withdrew from the case. During Judge Finch's stay on the bench, he repeatedly urged a compromise and even said the means were not lacking whereby this could be done. Judge Seawell of Oakland was then appointed and accepted, but after a brief stay found that his wife had relatives that had land in our district, and retired. Judge Albert Lee Stephens of Los Angeles was next appointed and accepted the task of trying the case.

After almost two years' delay, the case was opened November, 1921, with Judge Stephens presiding. The trial closed July 31, 1923.

Perpetual Injunction Ordered

Final arguments were made in Los Angeles in December, 1923, and Judge Stephens issued a memoranda opinion in May, 1924. Findings of fact and conclusions of law were filed in May, 1925; ordering the issuance of a perpetual injunction against the Lindsay Strathmore Irrigation District. In April, 1926, the judgment was filed, and concurrently therewith an order suspending the operation of the injunction, on terms, pending an appeal to the Supreme Court which the Lindsay District announced it would take. At the time the findings were filed in May, 1925, the attorneys for the district made a motion for an order suspending the injunction pending the appeal. Judge Stephens made an informal announcement that he would grant the motion. The plaintiffs then asked the Supreme Court for a writ of prohibition to prevent the entry of such order. This matter was argued before the Supreme Court En Bank at Los Angeles. That court three months later denied the writ.

The case is now in the Supreme Court on appeal. The record on appeal consists of 25,000 pages of transcript, over 700 exhibits and the judgment roll, which comprises 900 printed pages. The cost has been, including both sides, close to a million dollars. There has been some criticism of the length of this trial, but I wish to show to this convention, that our people are very grateful that we have been able to hold the water during this period. We have had an opportunity to strengthen our position during the past two years, by the acquisition of water stock in mutual water companies and corporations diverting water from the Kaweah River. This water stock represents an amount of water in acre feet, 50 per cent greater than any amount pumped in any one year by our district, and we are now devising ways and means of using this water, if our appeal to the Supreme Court is not successful.

The Lindsay District has one of the most modern irrigating systems which is based on a high duty of water. Thirty-nine pumping plants are located on the Rancho de Kaweah; about 20 miles of redwood pipe, 14 inches to 48 inches in diameter, lead from the rancho to a low line cemented canal, six miles long; this canal conveys the water to the main pumping station, three miles north of Lindsay. The total lift at the rancho is about 120 feet to the main pumping station; there it is boosted 162 feet to a gunite bench flume 6 miles in length. From this flume the water is taken out and distributed over the district by means of 100 miles of riveted steel pipe, varying in diameter from 4 to 36 inches, and is delivered to the consumers under pressures varying from 0 to 75 pounds.

The same supply is used for both domestic and irrigation purposes. At the end of the bench flume, two steel lines lead off, one 30 inches and another 36 inches in diameter. The first 4 miles in length supplies a second small booster station where another lift of 160 feet is made to serve 2000 acres on a higher elevation. At this last lift the water is place in a small cement canal three miles long and is distributed therefrom by steel lines. The system is 100 per cent metered, with loss from all sources of about 4 per cent. This includes the loss by metering as a whole at the source and distributing in small amounts.

Water Is All Metered

Our people like the meter system, and I am a firm believer that where individuals own their own plants the water should be metered, so that they can tell the amount used and have some idea that the application of water is near the amount needed for the crops being raised. The irrigation rate is $10.00 per acre foot and the domestic rate $20.00 per acre foot. This money is used on operation only, while bond interest and general funds are paid from direct taxes on all lands, the rate being the same on improved and unimproved lands. The average cost of water per acre which includes everything, including litigation, is about $26.00 per acre.

The balancing feature is taken care of by a small reservoir holding 20 acre feet, located about one-quarter mile beyond the last pumping station, and 25 feet higher. The pumps are connected with the line going to the reservoir, and the surplus, if any, goes by. If a short-

tage exists the same line carries the water back.

The irrigation season normally is about 210 days, depending greatly on the rainfall, and water use is based on a high duty and economic handling. The duty is about 1.6 acre feet per year. A certain amount is allowed per acre each thirty-day period, and the consumer is usually permitted to take the same in heads as needed. Very few services take as high as 35-inch heads, the average being about 15 inches. Our connected electric load is 3750 H.P., yearly use over 10,000,000 KWH, and the rate is about .8 of a cent per KWH and voltage on all motors 2200.

Many Interesting Problems

We have had some very interesting problems to meet in the operating features, especialy in the control and eradication of algae. If any one is interested I would be glad to answer their questions. The gunite bench flume is a unique piece of construction. I have a plan of it here on the wall and also a few pictures which may also be of interest to others.

The experience of the last ten years with the affairs of the Lindsay Strathmore District has caused me to form the opinion that no more dependable supply of water for irrigation purposes can be obtained, than that from underground basins. Nature has created many such natural reservoirs in California, of which that tapped by the Lindsay District is probably the best. The rains of the fall and winter, and the snow flow of the spring and early summer, are rapidly absorbed, and as rapidly extracted by the pumps. The rate of underground lateral percolation is so slow—about six feet a day—that little water escapes. In a climate where evaporation from water surface is so great—from 5 to 7 feet per annum,—the storing of water underground completely salvages this loss, provided the water table in the sands and gravels is not less than four feet below the surface. In my opinion the most economical method of conserving water is to take advantage of these natural storage basins, and by causing the surface flow of the streams to pass over wider areas, increase the absorption thereby. No more economical and permanent source of supply can be obtained.

Open Kansas City Office

The Barber-Greene Company has opened a new office in Kansas City, Missouri, at 2045 Main street. E. H. Cooper, district manager of the Barber-Greene Company will be in charge.

The complete Barber-Greene line, including ditchers, loaders, portable conveyors and coal handling equipment will be handled through this new office.

"COMMERCIAL" BUTTERFLY VALVES

"Commercial" Butterfly Valves are now made in ten styles to meet the many problems in Irrigation and Industrial work.

They are generally used in place of Gate Valves, as they are more easily and quickly operated and are much cheaper.

All parts are replaceable and require practically no fitting.

WRITE TODAY FOR ILLUSTRATED CATALOG AND PRICES ON ALL "COMMERCIAL" FITTINGS.

LEGAL *and* JUDICIAL

A DEPARTMENT CONDUCTED BY HANKINS & HANKINS

Colorado Rules on Disputed Election of Officers

Quo warranto held to be proper proceeding to oust officers of irrigation district.

The Divide Irrigation District of Colorado held an annual election to elect two directors, one for a vacancy and one as a successor to Canning who was president and director. At the election the relators were elected and the secretary so notified them, but that the old Board (Lockard and Canning) were in doubt as to the legality of the election, and the Board refused to issue a Certificate of Election.

The proceeding by way of quo warranto was commenced and in the case of Lockard vs. People ex rel. Hasselbush et al. 250 Pac. Rep. 152 (July 6th, 1926) the Supreme Court of Colorado held that this proceeding was proper to test the right to the offices, stating:

Newly elected directors as residents of the state and irrigation district, and claiming to be lawfully elected directors, *held* entitled to join in action in quo warranto to oust from office President and Secretary of the District who were trying to extend their own tenure of office and withholding certificate of election from relators.

Washington Supreme Court Defines "Reasonable Diligence"

Sets forth law of water rights as between appropriator and riparian owner.

In the case of Hunter Land Co. vs. Laugenour, 250 Pac. 41 (October 21, 1926) the Supreme Court of Washington considers many questions concerning the law of waters of that state. The controversy involved the rights of the various claimants to the waters of a stream known as Hunter Creek.

On the point of "reasonable diligence" the Court states:

"The evidence leaves but little doubt that the construction of the ditch by which the water was diverted was commenced in the year 1883 and completed in the year 1885. The rule is that when the actual diversion of water to a beneficial use on land is at a time later than the work of constructing the means by which it is diverted is begun, the time of diversion relates back to the beginning of the work only when the work has been pursued with reasonable diligence, so that the real question is, was the work in this instance pursued with reasonable diligence? It is our opinion that it was. The ditch was some 2½ miles in length, and for a part of the way it required the construction of a flume. The work of construction was thus of considerable magnitude, and it would seem that from the very nature of the work there was no lack of diligence. In addition to this, it was shown that Hunter was industrious and energetic and devoted his entire time to the work of developing his property.

Also on the question of the water rights as between appropriator and riparian owner and as between several riparian owners the Court sets forth the law as applied in Washington, as follow:

That lands of settlers are non-riparian does not affect water rights acquired by appropriation.

Private ownership of lands riparian to stream does not prevent appropriation of water for irrigation purposes for non-riparian lands.

All water rights, not attaching as riparian right to lands privately owned, may be appropriated by owners of other lands.

Riparian owners have coequal rights to use water for purposes of irrigation, notwithstanding settlement by one of them antedated the other.

Riparian right is not equivalent of right by appropriation, and cannot be exercised to exhaustion of waters, though needs of land require it, in disregard of rights of other riparian owners.

Riparian claimant, as against subsequent appropriator, has only right to take for irrigating purposes such proportion of water as his riparian land bears to quantity of riparian lands on stream capable of irrigation.

Another point of interest in this case is the remarks of the Court concerning the limitation of Riparian rights to "reasonable use." On this point the Court states:

The decision recognized our previously announced rule that a reasonable use of the waters of a stream for the purposes of irrigation was a right attaching to riparian ownership, and deduced therefrom the further rule that where all of the lands riparian to a stream were in private ownership, and where a reasonable use of the water for irrigation purposes by the riparian owners exhausted the supply of water the stream afforded, there was no room for an appropriation.

Montana Supreme Court Sets Limit as to Water Rights

When one has all the water required, or all his ditches can carry, his right to a greater flow is immaterial.

In the case of Tucker vs. Missoula Light & Water Co., 250 Pac. Rep. 11. (October 4th, 1926) the plaintiff recovers a judgment for the sum of $22,726.90 damages against defendant for the wrongful and unlawful diversion and use of water by defendant. The defendant in its answer sets up a prior right and also a defense based upon the fact that no water commissioner was appointed for the stream.

In affirming the judgment of the trial court the Supreme Court of Montana passes upon several points of interest.

As to the defense that no water commissioner had been appointed, the Court says:

Counsel for defendant asserts that the water code of Montana is "so complete a remedy for all water uses and for all wrongful uses of water on an adjudicated stream that it seems self-evident that the Legislative Assembly ... intended and designed this code as an exclusive remedy." We do not so view the statutes to which reference is made. A special statutory remedy is not exclusive, unless such intention is clearly manifest. It is merely cumulative, unless a contrary intention clearly appears and it cannot be otherwise than cumulative unless it is entirely adequate for the protection of pre-existing rights —The right to sue for damages for the invasion of a right existed under the common law, and exists under our code ... and the statutory remedy referred to by counsel must, if it is to supersede such right of action, be entirely adequate to protect the rights of owners of decreed rights at all time. It is therefore manifest that the remedy provided for (Code) is but cumulative.

On the question of the amount of water to which each of the parties was entitled, the Court quotes the following general rules of law:

The so-called "ownership" of water differs from that of personal property capable of corporeal possession. Neither the appropriator of water nor one to which a right is decreed owns the corpus of any part of the flow of the stream. He is entitled only to the beneficial use of the amount of water called for by his appropriation or decree when he has need therefor, and providing his distributing system has a sufficient capacity to carry such an amount of water. When his ditches are incapable of carrying the amount of water decreed to him, his right is measured by the capacity of his system of distribution, regardless of his needs. So long as a party has all the water his necessity requires or that his ditches will carry, it is immaterial that he has a right, under decree or otherwise, to a greater flow from the creek. It is his duty to permit the excess to remain in the creek or, having diverted it, to return it to the creek in such manner that it will be available to subsequent appropriators or decreed rights.

On the question of the amount of damages awarded, the defendant claimed that the same were excessive. On this

Digging, Cleaning Canals - *at Low Cost*

THE NEW RUTH DREDGER digs successfully in either dry or swampy ground. With its quick adjustable elevator, operating from either side of the dredger and its high speed endless chain of automatic self-emptying buckets and consequent uninterrupted flow of dirt, and ease of mobility, it operates at a minimum cost per cubic yard or lineal foot, heretofore considered impossible.

The RUTH cuts smooth even banks and bottoms—cleans canals, whether empty or filled with water, of all muck, sand, tulles, small willows and water grasses.

Write describing the type of work you contemplate doing and our engineers will gladly co-operate with you in selecting the dredger best adapted to your needs.

Send today for BULLETIN No. 9—it illustrates the NEW RUTH DREDGER, type and size of canals it digs or cleans, and gives specifications, maximum capacities, and operating costs.

OVERHEAD IRRIGATION

CONDUCTED BY WM. J. B. STEWART

HOW TO GET THE BEST COVERAGE WITH "OVERHEAD"

By H. A. WADSWORTH

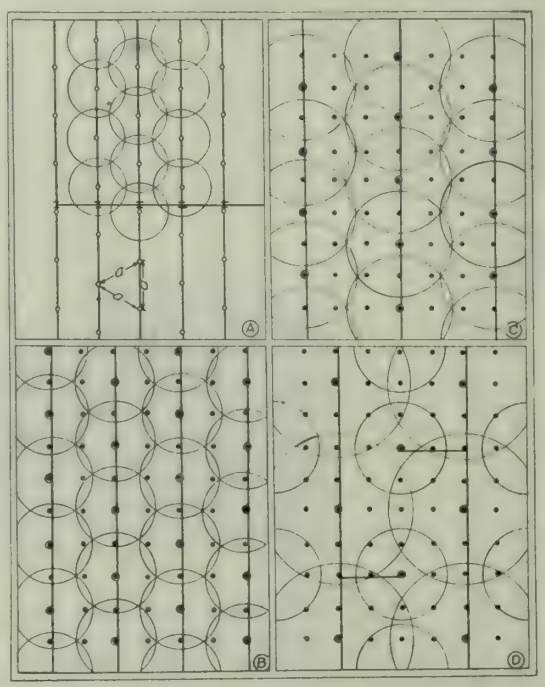
SPRINKLER installations for orchards, nurseries, and truck gardens fall into two general classes: perforated overhead pipes, sometimes called overhead nozzle lines, and revolving sprinkler systems which water circular areas.

Sprinkling heads cannot distribute water over a given rectangular area as uniformly as a well operated sprinkler line because of the overlap of the circles of application which are necessary to insure complete coverage. With field crops, nursery plantings, and truck crops, where the location of sprinklers is not rather rigidly fixed by planting arrangement, part of this objection can be obviated. When sprinkler heads can be located on a hexagonal pattern and every head placed at an equal distance from every other head adjacent to it, only about 15 per cent of the area served will be within the zones of overlap, provided the spacing to the spread which can be expected from a single head.

Location of Sprinkler Heads

In cases where the location of the heads cannot conform to a true hexagonal spacing because of the planting scheme—or for some other reason—the amount of overlap must be increased if complete coverage is provided. No real objection is offered by this necessary overlap, since all sprinkler heads throw less water to the extreme circumference of the circle of coverage than is applied to the central area. The overlap tends to equalize any lack of uniformity of application which may result from a single head.

Many commercial sprinkler heads now on the market throw water with fair uniformity over a circle with a 60-foot diameter when a pressure of from 15 to 18 pounds per square inch is available at the head. With an expected diameter of coverage of 60 feet, sprinkler heads should be located so that each head is 52 feet from its neighbors in every direction. Such a spacing can be effected by staggering the sprinkler heads on feed lines which are parallel and which are 45 feet apart. This plan of installation is evidently impossible in orchards that are planted on the rectangular system. Several plans of layout are shown in figure 1. In this figure, plan A is a hexagonal installation for truck gardens, nurseries, or for orchards planted on the hexagonal plan. Plans B, C, and D are superimposed upon rectangular orchard plantings.



LAYOUTS OF PERMANENT SPRINKLER INSTALLATIONS

A. A hexagonal installation reduces the overlap of circles of coverage to a minimum. Each head is the same distance from its neighbors in every direction. Such a method of installation is not adapted to orchards on a rectangular planting plan.

B. A common method of installation in rectangular plantings is to establish a sprinkler head in every second tree in every second row. The sprinkler heads are not equally spaced.

C. Economy in underground piping results when individual sprinklers can be located in every second tree in every third row. The distribution is lacking in uniformity.

D. When sprinklers of large diameters of coverage are used auxiliary sprinklers are sometimes installed to insure complete coverage without excessive overlap

In orchards set on the rectangular plan, with 24-foot spacings, a close approximation to the ideal installation suggested above can be reached by establishing sprinkler heads in alternate trees in alternate rows. When such a scheme is adopted, the diameter of a single circle of coverage must be two and one-half times the distance between trees, if complete coverage is to be obtained with a minimum of overlap. Under the condition given the diameter required for most efficient coverage is 60 feet.

Some growers object to locating heads directly over a tree. The accumulation of excess water at the trunk of the tree, because of unavoidable leaks in the sprinkler heads, and the difficulty of handling fumigation tents over trees equipped with sprinkling stands, are given as criticisms of this method. Growers who disapprove of such an arrangement sometimes install sprinklers in the centers of the tree squares. The diameter of coverage is the same in either case. Some obstruction to cultivation must be caused by an installation in which the sprinkler pipes rise from the centers of the tree squares. must be allowed to obtain complete coverage. If sprinkler heads are placed in every third tree in every second row, the circle of applica-

Special Heads Cause Overlap

Some types of sprinkler heads are designed for greater coverage than the 60-foot diameter usually served by the more common heads. It is difficult to use these special heads advantageously in orchards on common spacings, because of the unavoidable overlap which

Development of Activated Sludge Process

(*Continued from Page 44*)

monly found. The period of detention is from one to four hours.

Sludge Disposal Problem

The collected sludge contains 98-99.5 per cent of water and is easily handled by air lifts, pumps, or some type of ejector. A portion is returned to the sewage influent and the remainder to the sludge disposal system. The amount of sludge found necessary to return to the aeration tanks for best results varies from 12.25 per cent of sludge by volume. This amount can only be determined by experiment and is usually about 20 per cent.

The satisfactory disposal of the sludge produced by the activated sludge process offers, perhaps, the biggest problem found in such plants. The sludge from the clarifiers is a brown flocculent mass of organic matter of high bacterial content. It is slow to dry on sand beds, does not filter easily, and is difficult to handle in artificial driers. Efforts to get it into a form that can be readily sold as fertilizer, have not met with much success without excessive costs. A large amount of work has been done at Milwaukee, Chicago, Houston, and elsewhere in an effort to make this an economic possibility. Various mechanical filters have been tried in an effort to get sludge in a condition in which it can be readily dried.

The treatment of the sludge with various chemicals such as sulphur dioxide, sulphuric acid, alum and ferrous sulphate has been tried in hopes of increasing its rate of filtration and has met with varying success. It is found that sludges from different sewages react differently under the same treatment. In the arid and semi-arid regions of the Pacific Coast it is likely that sand drying beds will be successful. This method has been used with good results at Lodi. The sludge must be placed in much shallower depths than would be used with Imhoff sludge. The method of sludge disposal in use at Indianapolis and Houston is to pump the sludge to large lagoons. The lagoons are usually underdrained. The sludge decomposes and partially dries with some odor and is flushed into a nearby stream during high water. Another method is to use the sludge for direct irrigation on agricultural land. Perhaps the most promising method is to digest the sludge, after mixing it with the coarse material taken out by preliminary treatment in Imhoff tanks. This not only offers a method for disposal of the coarse material but dewaters the sludge so that it can be more readily dried on sand beds. This causes the loss of some of the fertilizing value and greatly increases the initial cost of the plant. Researches have indicated that two or three times as much sludge capacity is required as is necessary in an Imhoff installation without activation.

Increasing Filter Capacity

The use of activated sludge plants as a preliminary treatment for sprinkling filters offers a promising future. The effect is to relieve the load of the filters, thereby increasing the filter capacity.

Surprisingly large increases are possible in the dosage applied to the filters by the use of only limited detention periods in the aeration tanks. This makes it possible to supplement sprinkling filter systems with standby activated sludge units for use during peak periods. These periods of high flow are common in California as in resort cities having a large seasonal fluctuation in population, and in cities with seasonal industries such as canneries and packing houses.

The sanitary disposal of the trade wastes from many industrial plants is one of the biggest problems of the sanitary engineer. The advent of the activated sludge process and its application to trade waste problems, has opened up a new field for investigation. It is found that some of the wastes can be successfully treated by this method if fixed with domestic sewage, but not if treated separately without excessive costs for chemical precipitation. This again, is a problem which varies with individual plants and must be solved by local study of each particular trade waste.

There is no doubt but that the trade waste problems of many cities could be solved by properly designed activated sludge plants and that further studies will perfect methods for treatment of wastes not at present successfully treated.

The comparatively high cost of activated sludge plants has been one of the main objections to their adoption. The mechanical types show a power economy and require less labor attendance. So far, data on the depreciation charges for this type are too meager to warrant any definite conclusions. It would seem that some form of mechanical aeration eventually will be found that will be the most economical form of activated sludge plant, especially for small installations.

The initial cost of an activated sludge plant is no greater than that of other methods giving as high grade of effluent.

The higher operating cost of activated sludge plants over other methods is due to more mechanical devices, higher power cost, and a greater labor overhead. The cost per million gallons, including depreciation, interest, labor, power, etc., has been found to run from $20 to $50 in the few plants where data are available. The initial cost of the plants varies from $10 to $30 per capita.

The wide variation in these cost figures serves to emphasize the fact that each municipality has a separate sewage disposal problem of its own and that cost data of other cities may not be at all applicable. Thorough preliminary investigation is necessary to economically design a sewage disposal system, whether it be an activated sludge plant, or one of the other types.

SURVEY *of* HYDRAULIC DEVELOPMENT

As Shown by Official Records of the Month -- Local, State, and Governmental

Applications Filed

Among the applications for permit to appropriate water filed with the State Department of Public Works, Division of Water Rights (California), during the month of November, 1926, were the following:

Application No. 5263 (San Bernardino County—Noah Adair, c/o David W. Richards, attorney, 218 Katz Bldg., San Bernardino, Calif., for 0.67 cubic foot per second from a spring tributary to Cajon Canyon to be diverted in Sec. 32, T 2 N, R 5 W, S. B. M. for agricultural purposes on 10 acres. Estimated cost $500.

Application No. 5265 (Butte County)—Walter J. O'Neill, c/o Polk & Robinson, Chico, Calif., for 0.5 cubic foot per second from Dicus Pond to be diverted in Sec. 24, T 23 N, R 2 W, M. D. M., for agricultural purposes on 40 acres.

Application No. 5266 (Tuolumne County)—Turlock Irrigation District, Turlock, Calif., for 80,000 acre feet per annum from Middle Fk. of S. Fk. of Tuolumne River and Big Creek tributary to San Joaquin River to be diverted in Secs. 23 & 34, T 1 S, R 18 E, M. D. M., for irrigation purposes on 181,490 acres. Estimated cost $5,574,000.

Application No. 5267 (San Diego County)—S. W. Swan, c/o F. A. Wilkie, P. O. Box 735, National City, Calif., for 1.00 cubic foot per second from San Filipe Creek to be diverted in Sec. 5, T 13 S, R 4 E, S. B. M. for agricultural and domestic purposes on 35 acres. Estimated cost $50,000.

Application No. 5269 (Stanislaus County)—C. C. Crookshank, c/o L. J. Maddux, attorney, Modesto, Calif., for 2.54 cubic feet per second from Tuolumne River tributary to San Joaquin River to be diverted in Sec. 17, T 4 S, R 8 E, M. D. M. for agricultural purposes on 203 acres. Estimated cost $3,500.00.

Application No. 5270 (Butte County)—N. Stephenson, Biggs, Calif., for 0.37 cubic foot per second from Lateral "H" of Reclamation Dist. 833, tributary to Butte Creek and Sacramento River to be diverted in Sec. 24, T 18 N, R 2 E, M. D. M. for agricultural purposes on 30 acres. Estimated cost $600.

Application No. 5271 (Madera County)—Woman's Board of Home Missions of the Presbyterian Church in the U. S. A., 156 5th Ave., New York, N. Y., for 0.02 cubic foot per second from 2 springs tributary to Peckinpah Creek and San Joaquin River to be diverted in Sec. 17, T 8 S, R 23 E, M. D. M. for irrigation and domestic purposes on 4 acres. Estimated cost $500.

Application No. 5272 (Yuba County)—F. W. Johnstone of Walnut Creek, Calif., for 200 cubic feet per second and 10,000 acre feet per annum from Yuba River tributary to Feather River to be diverted in Sec. 30, T 16 N, R 6 E, M.D.M. for agricultural purposes on 15,000 acres. Estimated cost $250,000.

Application No. 5273 (Ventura County)—C. C. Capley, R. F. D. No. 3, Box 291, Pasadena, Calif., for .40 cubic foot per second from Tinta Creek tributary to Cuyama River to be diverted in Sec. 32, T 8 N, R 24 W, S.B.M. for irrigation and domestic purposes on 120 acres.

Application No. 5259 (Riverside County)—Winfield Hogaboom, as trustee and agent of Romola Water Co., c/o Hunter & Farraher, attorneys, 900 I. N. Van Nuys Bldg., Los Angeles, Calif., for 20 cubic feet per second from San Jacinto River to be diverted in Sec. 2, T 4 S, R 2 W, S. B. M. for irrigation and domestic purposes on 7000 acres. Estimated cost $190,000.

Application No. 5279 (Stanislaus County)—C. C. Turner, P. O. Box 142, Oakdale, Calif., for .69 cubic foot per second from Stanislaus River tributary to San Joaquin River to be diverted in Sec. 17, T 2 S, R 10 E, M. D. M. for agricultural purposes on 55 acres. Estimated cost $880.

Application No. 5280 (San Diego County)—Neil Rasmussen, c/o T. H. King, 920 8th St., San Diego, Calif., for 1.17 cubic feet per second from Viejas Creek tributary to Sweetwater River to be diverted in Sec. 30, T 15 S, R 3 E, S. B. M. for municipal purposes in Sandy Rock. Estimated cost $50,000.

Application No. 5281 (San Diego County)—Neil Rasmussen, c/o T. H. King, 920 8th St., San Diego, Calif., for .50 cubic foot per second from Viejas Creek tributary to Sweetwater River to be diverted in Sec. 35, T 15 S, R 2 E, S. B. M. for municipal purposes proposed subdivision. Estimated cost $20,000.

Application No. 5282 (Butte County)—C. M. Faris Estate, c/o Geo. D. Adams, 2131 F St., Sacramento, Calif., for 16.40 cubic feet per second from Lateral "E" of Reclamation Dist. 833 tributary to Butte Creek and Sacramento River to be divered in Sec. 26, T 18 N, R 2 E, M. D. M. for agricultural purposes on 656.2 acres of rice. Estimated cost $2,000.

Application No. 5284 (Madera, Merced and Mariposa Counties)—Webb & Sheller, La Grande, Calif., for 60,000 acre feet per annum from Chowchilla River tributary to San Joaquin River to be diverted in Sec. 18, T 7 S, R 20 E, M. D. M. for irrigation purposes on 20,000 acres. Estimated cost $400,000.

Application No. 5287 (Butte County)—Harry Howard, Chico, Calif., for .5 cubic foot per second from Dicus Pond to be diverted in Sec. 24, T 23 N, R 2 W, for irrigation purposes on 40 acres in Sec. 24.

Permits Issued

Among the permits to appropriate water issued by the Department of Public Works, Division of Water Rights, California, during the month of November, 1926, were the following:

Permit No. 2662, Application No. 4851 (Placer County) Issued to Pacific Gas & Electric Co., San Francisco, Calif., Nov. 10, 1926, for 300 acre feet per annum from Six Mile Valley in Sec. 25, T 17 N, R 12 E, for irrigation and domestic purposes. Estimated cost $1500.

Permit No. 2667, Application No. 4514 (El Dorado County) Issued to S. F. Akin, Placerville, Calif., Nov. 15, 1926, for .62 cubic foot per second from Cold Springs Branch in Sec. 2, T 10 N, R 10 E, for domestic and irrigation of 50 acres in Secs. 9 and 10. Estimated cost $150.

Permit No. 2668, Application No. 4903 (Los Angeles County) Issued to Haines Canyon Rock Co., Tujunga, Calif., Nov. 16, 1926, for .11 cubic foot per second from a well in Sec. 18, T 2 N, R 13 W, for industrial and domestic purposes in Sec. 18. Estimated cost $4500.

Permit No. 2670, Application No. 5031 (Sacramento County) Issued to Mary K. Deterding, Sacramento, Calif., Nov. 18, 1926, for 4.85 cubic feet per second from American River, movable point in Section 22 and 28, T 9 N, R 6 E, for irrigation of 387.79 acres near point of diversion. Estimated cost $3500.

Permit No. 2672, Application No. 5078 (Marin County) Issued to H. W. Thompson, Nicasio, Calif., Nov. 19, 1926, for .32 cubic foot per second from an unnamed stream in projected Sec. 1, T 2 N, R 8 W, for domestic and irrigation of 25.66 acres near point of diversion. Estimated cost $500.

Permit No. 2673, Application No. 5080 (Napa County) Issue to E. Bonzi, Napa, Calif., November 22, 1926, for 3.66 cubic feet per second from Putah Creek in Sec. 9, T 8 N, R 3 W, for irrigation of 293 acres near point of diversion. Estimated cost $3000.

Permit No. 2674, Application No. 5075 (Shasta County) Issued to D. J. Kirby, Castella, Calif., Nov. 22, 1926, for 0.1 cubic foot per second from North Fork of Castel Creek in Sec. 1, T 38 N, R 5 W, for domestic and irrigation of 8 acres near point of diversion. Estimated cost $500.

Permit No. 2675, Application No. 5201 (San Joaquin County) Issued to Fred H. Finck, Stockton, Calif., Nov. 23, 1926, for 3 cubic feet per second from Old River in Sec. 12, T 2 S, R 4 E, for irrigation of 245.3 acres near point of diversion. Estimated cost $4,000.

Permit No. 2677, Application No. 5001 (Alameda County) Issued to County of Alameda, Oakland, Calif., Nov. 26, 1926, for .5 cubic foot per second and 60 acre feet per annum from Arroyo del Valle, in Sec. 4, T 4 S, R 2 E, M. D. M. for domestic and irrigation of 65.85 acres in Secs. 3 and 4. Estimated cost $30,000.

Whittier Water Company has applied to the California Railroad Commission for authority to issue $70,000 of notes for the purpose of renewing outstanding notes and $16,500 of notes payable in three years, for the purpose of financing improvements.

Coverage with "Overhead"

(*Continued from Page 50*)

tion from a single head must have a diameter equal to about three and one-third times the distance between the trees. With trees planted on 24-foot distances, for example, the diameter of application required would be about 80 feet, and undesirable inequalities in application would necessarily result.

Some manufacturers, particularly those who specialize in sprinkling devices for golf greens, offer sprinklers with great diameters of coverage for orchard use. The advantage in using such heads lies in economy in underground piping. The great disadvantage is that undesirable inequalities of distribution must exist if the sprinkling heads be located with respect to existing tree rows. In some installations with large-diameter heads, a dry area is allowed to remain between the circles covered by four large sprinklers. This dry area is covered by a small sprinkler fed from a lateral leading from the nearest main.

Legal and Judicial News

(*Continued from Page 48*)

point and in support of the verdict, the Supreme Court states:

It is asserted that the amount of the verdict shows that it was given under the influence of passion and prejudice, and it is pointed out that the damages awarded for a partial loss of crops would equal or exceed the purchase price of the land on which the crops were grown, including the water right. The purchase price of the land, or its value, cannot affect the value of crops raised thereon. It is not beyond the realm of possibility that a purchaser might pay the entire purchase price of his land and water right out of three years' crops. The question for determination is whether, under the evidence adduced, the amount awarded is justified.

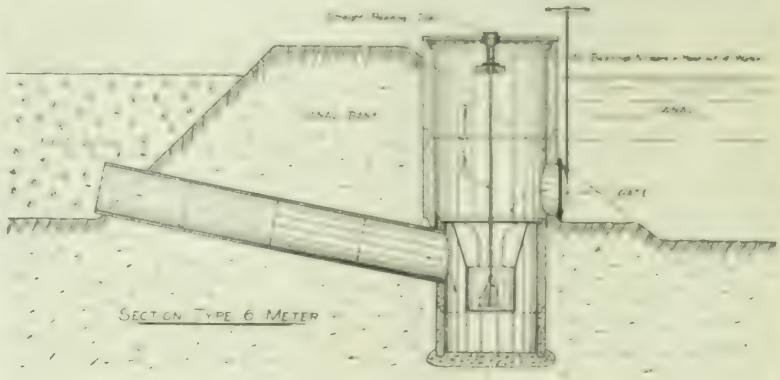
Vista Uses "Rule of Reason"

(*Continued from Page 17*)

vised as a "speeding up" measure. Undoubtedly this bonus has had the desired effect for a rush of applications have been filed to secure this advantage during the first year. In the interval from the completion of the system in March, applications covering 7283 acres have been made and something over 275 individual service meters have been installed.

Meeting some opposition from the land owners at the outset because of the novelty of the plan and failure to grasp the manifest advantages to the small land owner, the results have been so satisfactory and the advantages so apparent that much of the rapid advancement of the district is ascribed by those most closely associated with the enterprise, to this ingenious handling of a perplexing business problem.

The RELIANCE METER



THE "Type 6" Reliance Irrigation Meter offers you standardized permanent construction at a very low first cost. Their sustained efficiency with a minimum of upkeep has been proven by 12 years usage. Cut shows installation of the 4 sec. ft. size in 24 and 30-inch concrete pipe. This is the standard type of setting adopted by many irrigation districts in Texas and elsewhere who are now equipping all their deliveries with this device. The "Type 6" meter is furnished in sizes ranging from ½ up to 16 sec. ft.

PARSONS

The Parsons Model 21 Special Irrigation Ditching Machine has proven in its work for the United Concrete Pipe & Construction Co., near Ventura, Calif., that it is designed to lower the cost of ditching. Its sturdy construction and great digging ability combined with its economy of operation mean lowest ditching costs for you. It digs a ditch with a maximum width—so far—of 43 inches; by 48 inches deep.

These machines now ready for delivery

Corrosion Problems of a Water System

(*Continued from Page 33*)

passing very close to the rails will have large stray currents, and these currents are likely to leave over restricted areas, causing more concentrated corrosion.

The current strength in pipes cannot always be used as an index of electrolysis hazards. Relatively large currents may be flowing on a pipe without causing any corresponding damage for the reason that these currents do not flow to the soil. On the other hand, relatively small currents may be flowing along the main and yet corrosion may be taking place.

Heretofore our greatest difficulty encountered in electrolysis testing has been our inability to measure directly the factor responsible for the corrosion, namely, the density of the current flowing from a pipe to earth. It was evident, therefore, that there was a need for improved means of electrolysis testing, whereby it would be possible to determine the polarity of the pipe with respect to earth, and for the quantitative measurement of current density at any desired point in the earth.

An earth current meter was developed by Burton McCollum of the United States Bureau of Standards and was described in some detail in the Electric Railway Journal of November 21, 1921. This instrument enables one to determine the actual density of current discharge from the pipe which is measured in terms of milliamperes per square foot of pipe surface. We have used this instrument for electrolysis testing for the past two years and have found it to be well adapted for use under practical conditions. By the use of this instrument, information can be had showing far more definitely the actual electrolysis conditions prevailing on any particular point than it is possible to secure by any other means heretofore available. This instrument is the best means available whereby it is possible to differentiate between natural soil corrosion and corrosion from stray currents.

Cooperative Treatment

When stray current flows into the earth, many different utilities owning underground structures are affected; hence the problem of electrolysis is one which is preeminently adapted to cooperative treatment. When each interest cares for its problem independently then each is partly undoing the work of others and a condition arises where money is being spent in producing systems that afford only temporary relief.

Such a condition is to be found where each utility attempts to apply to drainage system independent of all other utilities. It is easy to understand how confusion often arises when, say three companies apply drainage systems independent of each other, and large differences of potential exist between them. The three systems are in many ways in conflict, and very often rapid corrosion takes place.

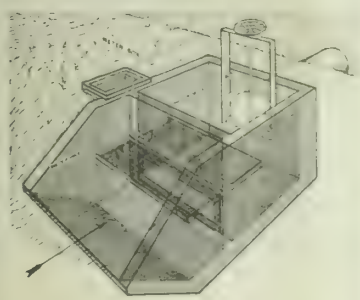
Troubles in various utilities finally reached a point when it was realized that stray electric currents could be best controlled by coordination of effort on the part of all interests. As a result a committee of representatives of all interested utilities in the East Bay Cities was organized in 1922 to determine the causes of damage to underground structures and recommend measures for their mitigation through means of cooperation among the interests concerned. Such assistance in the way of testing instruments, engineers, draftsmen, field employees, transportation and office space are contributed by the various member organizations. This committee holds monthly meetings to discuss the technical phases in connection with reports of tests and investigations that have been made during the current month and makes recommendations for protective measures. It recommends tests and investigations to be made and indicates the methods to be followed in making such tests and investigations.

How Committee Works

Regular surveys are made of the railway systems and the various underground structure systems, and include such measurements as: Current of station loads, rail gradients, overall potentials, difference of potential between rails and underground structures, current on underground structures, difference of potential between different structures and earth current measurements. These tests comprise to date over 2000 24-hour recording charts and 6000 readings from indicating meters. Test on railway systems required over 800,000 feet of wire which had to be strung on pole lines.

In addition to regular tests, this committee also investigates special cases of corrosion and installs pilot wires and drainage cables. Many serious cases have been corrected through committee activities at a minimum of expense to the interests affected.

The work of this committee has rendered valuable service in the installation and maintenance of drainage systems. An agreement was reached whereby drainage cables from the various underground structures were run to the most convenient manhole, either telephone or electric light and these connected to the



Submerged Orifice Measuring Structure

acre foot meter and turn out gate combined.

The installation cost of this unit is remarkably low. Write for design catalog.

Now in Our New Plant and in Production

Kimball satisfied pump owners compelled us to build a new and more commodious plant. We have now the most modern pump manufacturing plant on the coast, fully prepared to take care of all your pump needs. **And in production.**

We welcome visitors and inquiries

FRANK J. KIMBALL CO.

1012 E. 62nd St.,

Los Angeles, Cal., U.S.A.

negative return on a common bus bar. Such an arrangement makes it possible to insert resistance grids in series with drainage cables in order to equalize the potential between various underground structures.

This committee makes monthly tests of return current on all drainage systems as a precaution against damage from broken drainage connections or unusually large currents being drained due to changes or additions to the various structures. Tests are taken periodically to check the voltage conditions existing between the various structures, and steps are immediately taken to correct any dangerous conditions that might be found.

Cooperative treatment of electrolysis problems has been proven successful in a number of cities throughout the country, and is now generally recognized as representing the best practice in electrolysis prevention.

Water for Special Purposes

(Continued from Page 29)

portion of the crop area is in alfalfa, as in the San Joaquin and Imperial Valleys, greater amounts are used, varying from 2 to 3 feet depth per annum delivered at the land.

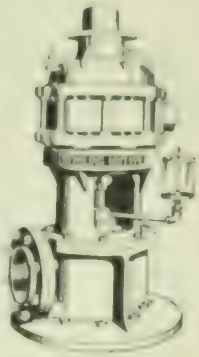
The question as to the relative quantity of water which will be required when an irrigated area is annexed to a growing city, with the prospect of the land being subdivided and used for other purposes, is one of growing importance. The past experience at Los Angeles has been, that as irrigated lands are subdivided and become residential in character with one-family houses surrounded by lawns and gardens, the water requirement remains unchanged or at least does not exceed that for irrigation. The data assembled in this paper confirm this experience and indicate that the same rule would hold for residential cities generally in California, including those in the region of San Francisco Bay.

The rule does not hold, however, for cities with population density exceeding 9 or 10 per acre. In such communities the population has begun to live on more than one floor level, apartment houses and flats are in evidence and commercial activities and industries have become established with greater demands upon the water supply.

For residential cities in California the rule will probably continue to hold, but as such cities become more metropolitan in character, and industries are established, there will undoubtedly be a change. There are thus very definite limits within which urban water requirements can be considered as acre for acre identical with that for irrigation.

Sterling Quality CENTRIFUGAL PUMPS

VERTICAL PUMPS for Surface or Pit Pumping. Same construction features as the split case Centrifugal Pump. Sizes—1½ in., 2 in., 3 in., 4 in., 5 in., 6 in., & 8 in. Send for bulletin No. 21.



Sterling Unitype Drive
The Original

Deep Well Turbine Pumps

Made for the following well diams.: 4 in., 6 in., 7 in., 8 in., 10 in., 12 in., 14 in., 16 in., 18 in. and 20 in. Capacities 20 G.P.M. to 4,000 G.P.M. Send for Bulletin No. 16

NOTE—The motor drive for this vertical pump interchanges with the deep well Turbine Drive.

AMONG OUR CONTRIBUTORS

Editorial Jottings About Current and Forthcoming Feature Articles, Dealing With Practical Problems of Hydraulics, and the Men Who Have Written Them

MAJOR CHARLES R. OLBERG, who furnished the information for the staff article on the Coolidge Dam, is assistant chief engineer with the U. S. Indian service. He was graduated from George Washington University in 1900 and was appointed structural draftsman in the Supervising Architect's office, of Washington. The next year he was made assistant hydrographer with the U. S. Geological Survey, and in 1902 he became assistant engineer with the U. S. Reclamation Service. In 1905 he was appointed structural engineer in the United States Quartermaster's Corps. In 1907 he was made supervising engineer with the U. S. Indian Service, a position he held until the United States entered the World War. During the war he was captain and then major in the engineering forces. Since 1919 he has held his present position of assistant chief engineer with the U. S. Indian Service.

Major Olberg's career has been marked by many important achievements. He was in charge of the preliminary work, including the design, of the Roosevelt dam; he constructed the Ashurst-Hayden Dam; and was in charge of the design and part of the construction of the Sacaton dam and bridge. These three projects, as well as the one on which he is engaged at present, the San Carlos project, are located in Arizona. Major Olberg is known as the inventor of a design for pumping from rivers, and an erosion control method, as well as of the multiple-dome type of dam.

GEORGE S. HENRY, who contributed last month an account of the water allocation problem of the Vista Irrigation district writes in this issue of some of the management problems of the district. Mr. Henry is *ex*-president of the Vista Irrigation district and not its president, as was erroneously stated in the last issue.

LOUIS MEYER, author of the article entitled "Melones Dam Completion Marks End of War Between Districts and Power Companies," has been an interested observer of activities on the Melones project from its earliest inception. As publisher of the Oakdale *Leader*, he has contacted with the financial, technical and construction sides of the work on the dam through every stage of its progress, and he reports the story to the readers of MODERN IRRIGATION in a popular and non-technical style which reveals, nevertheless, a familiarity with the history and the development of the project in all of its several interesting phases.

GEORGE W. TRAUGER

Mr. Trauger is superintendent of the Lindsay Strathmore Irrigation District in California. His paper on "Problems of a Sub-Surface Water Supply," read before the recent annual meeting of the California Section, American Water Works Association, is published in this issue through the courtesy of the editor of the Journal of the American Water Works Association.

H. A. WADSWORTH, who writes on "Coverage in Overhead Sprinkling," has prepared a bulletin, published by the California Agricultural Extension Service, on "Irrigation by Overhead Sprinkling," which is said to be one of the most comprehensive discussions of the subject as a whole that has yet appeared. His article in this issue is an excerpt from that bulletin. Mr. Wadsworth is assistant professor of Irrigation Investigations and Practice in the College of Agriculture, University of California, and is also assistant irrigation engineer in the Experiment Station of the University.

CHARLES H. LEE, who contributes the "Data on the Use of Water for Special Purposes" is well known to the readers of MODERN IRRIGATION. Through his many years of experience with the various phases of the water problem he is enabled to speak with authority on the subject. A graduate of the University of California, he was appointed hydrographer with the U. S. Geological Survey in 1905. In 1906 he became a member of the engineering staff of the Los Angeles aqueduct. In 1912 he was put in charge of underground water investigations of the California State Conservation Commission in Southern California. In 1919, on his return from service with the American Expeditionary Forces in France, he was made president of the California State Water Commission, and later became chief of the Division of Water Rights, State Department of Public Works. Mr. Lee is at present engaged in private practice as consulting engineer in San Francisco.

IN AN EARLY ISSUE, MODERN IRRIGATION expects to have an account of the very interesting irrigation system on the ranch of W. K. Kellogg, near Spadra, California. The novel feature of this installation is its remote automatic control which reduces to a minimum the possibilities of human error. This account has been written for the magazine by Adolf H. Koebig, senior partner of the firm of Koebig and Koebig, who designed the system. Mr. Koebig has his engineering degree from the University of Karlsruhe, Baden, and has followed his profession in Germany and the United States for more than fifty years, during some forty of which he has been a noted figure in engineering circles in Southern California.

AMONG THE OTHER interesting features in our forthcoming numbers will be an article by A. K. Warren, chief engineer of the Bureau of Sanitation, Los Angeles County, giving a detailed account of the new sewage treatment plant being constructed south of Watts, Calif.
